In the Diagnostic and Statistical Manual of Mental Disorders, fifth edition, text revision (DSM-5-TR), the criteria for bipolar and related disorder due to another medical condition were updated to enhance their clarity and consistency. The changes were approved by the DSM Steering Committee and APA Assembly and Board of Trustees.

**Rationale for Change**

In DSM-IV, criterion A for “substance-induced mood disorder” and “mood disorder due to a general medical condition” (i.e., the criterion that defined the symptoms that must be prominent) were identically worded. Following the elimination of the DSM-IV “mood disorders” grouping in favor of a “bipolar and related disorders” grouping and a “depressive disorders” grouping in DSM-5, a splitting of the DSM-IV categories for substance-induced mood disorders and mood disorder due to a general medical condition into their bipolar and depressive disorder components was required. This led to differences in wording of criterion A which could have resulted in the criterion mistakenly being interpreted as requiring elevated, expansive, or irritable mood or markedly diminished interest or pleasure in all, or almost all, activities, which was not the intent. Moreover, if it is read in the intended way, i.e., that the “with or without” applies both to depressed mood and diminished interest or pleasure in activities, these phrases become superfluous as they carry no diagnostic weight. Hence, the criterion was reworded in DSM-5-TR to be clearer and match that in “substance/medication-induced bipolar and related disorder” and “depressive disorder due to another medical condition” to enhance the consistency in its application.
