No. 1

An Unusual Case of Recurrent Cannabis-Induced Flashbacks

Poster Presenter: Alexander Maksymenko, M.D.
Co-Authors: Adenike Ishola, M.D., M.P.H., Tolulope A. Olupona, M.D., Oluwole Jegede, M.D., Kodjovi Kodjo, M.D., Mario Gustave, M.D., Ayodeji Jolayemi, M.D.

SUMMARY:
Introduction: Flashbacks are sudden, involuntary, and vivid memories of past personal experiences. In many cases, these powerful memories are closely linked with traumatic events. The association of psychedelic drugs such as Lysergic acid diethylamide (LSD) or Phencyclidine (PCP) with flashbacks is well documented, however, although the association of Cannabis with flashbacks is well known, such phenomena are not well documented and its physiology still appears elusive. The use of cannabis in the United States is still considered illegal under federal law, however according to the 2013 surveys of National Institute of Health (NIH), marijuana use has increased dramatically over the past decade. Although, about 9.5 percent of Americans reported use of marijuana, 30 percent of users meet the criteria of cannabis use disorder. Cannabis induced flashbacks can be misdiagnosed as hallucinations or can overlap psychotic symptoms. Case Summary: We report the case of a 35-year-old African American woman with a past medical history of HIV and an unclear psychiatric history. The patient was brought to the Emergency Department by EMS activated by her husband for a psychiatric evaluation. She was reported to be acting odd and bizarre, disorganized, and talking to herself. A review of the patient's medical records showed a past history of auditory hallucinations and paranoia following her use of K2. On further evaluation, the patient stated that her symptoms were precipitated specifically by the scent of her husband's fragrance. She describes a recurrence of these episodes. She further relates a relationship between her symptoms and her heavy marijuana use, she endorses smoking "a few blunts" two days before the incident. The patient stated that she always gets flashbacks of her sister's death each time she smells the peculiar scent of her husband's cologne. The patient was treated with Risperidone 1 mg PO daily for Cannabis induced psychotic disorder. The patient's symptoms responded well to a trial of antipsychotics along with psychotherapy. Her symptoms subsequently resolved and she was discharged with aftercare follow-up. Discussion: Cannabis is a psychoactive drug which is widely consumed in industrialized countries and around the world. One of the described effects of Cannabis use include the flashback phenomena. With psychedelic agents, flashbacks often occur as transient, spontaneous recurrences of the drug effect and it tends to appear after a period following use particularly in heavy users. The individual usually re-experiences a visual hallucination or other perceptual disturbance triggered by a familiar smell that takes them back to a special or poignant moment like in our index case. This case illustrates the clinical presentation of cannabis use which might have triggered flashbacks in a young African American woman.

No. 2

Little Known Substance, Kratom, Causing Opioid Like Withdrawal in 57-Year-Old Patient Seeking Detox

Poster Presenter: Ashley Bindshedler, D.O.

SUMMARY:
A 59-year-old Caucasian male with a past psychiatric history of alcohol use disorder, cocaine use disorder, and opioid use disorder and cured Hepatitis C presented voluntarily for kratom detoxification. Kratom is a plant based substance with active ingredient of Mitragynine, a supraspinal mu and delta agonist with a 3.5 hour half life. Kratom has been used historically as a stimulant or for pain relief by ingesting raw leaves or steeping them in tea, other methods include ingesting capsules or smoking the leaves. This patient began taking 42 capsules spread out over the course of the day for 5 weeks with last use being 1 day prior to admission. While on kratom, the patient experienced symptoms of euphoria and relaxation. He reported withdrawal symptoms of anxiety, nausea, mild constipation, irritability, fatigue, myalgias, cravings and poor sleep. He denied depression, suicidal/homicidal thoughts, hallucinations, or delusions. He was

medically cleared, admitted to the psychiatry unit and successfully detoxed off kratom with the opioid withdrawal protocol of Clonidine 0.1 mg TID PRN, methocarbamol 1500 QID PRN, loperamide PRN and ondansetron PRN which the patient found helpful. There have been other case reports where patients have used kratom to manage their chronic pain and detoxify off opioids. There have also been reports where kratom may have been a contributor to patient death. The purpose of this project is to remind providers that new substances will continue to be used by patients and it is important to stay educated on these substances. Specifically, this project will address the pharmacology and the symptoms of intoxication, withdrawal and proposed treatment modalities for kratom use and share different resources providers can use to learn about new substances.

No. 3

Development and Validation of Selfie Addiction Scale

Poster Presenter: Awadhesh P. Singh Solanki, M.B.B.S.

SUMMARY:

Aims and Objectives The aim of this study was to develop a self-diagnostic Selfie Addiction Scale. In addition, the reliability and validity of the Selfie Addiction Scale was demonstrated. Background This is probably first Selfie Addiction Scale developed according to different sources. Method A total of 200 participants were recruited from July to September 2015 to complete a set of questionnaires including 47 items. The participants consisted of 88 boys and 112 girls; with ages ranging from 18 to 28 years (Mean=21.15, SD=2.95 years). Factor analysis, t-test, ANOVA, and correlation analysis were conducted to verify the reliability and validity of this scale. For concurrent validity we used Smartphone Addiction Scale-Short Version (SAS-SV), Internet Addiction Test (IAT) by Dr. Kimberly Young, Measure of Body Apperception (MBA), Visual Analogue Scale (VAS), Barratt Impulsiveness Scale (BIS-11), Rosenberg-self Esteem Scale, Narcissistic Personality Inventory (NPI16) , CAGE questionnaire and substance dependence and abuse diagnosis of DSM-V. Results The internal consistency and concurrent validity of selfie addiction scale were verified (Cronbach's alpha?=?0.962). Selfie Addiction Scale and its sub-scales were significantly correlated with other scales. The visual analogue scale of each factor also showed a significant correlation with each sub-scale. Conclusions As selfie is becoming a new form of addiction among people in the community, Selfie Addiction Scale which showed good reliability and validity for the assessment of selfie addiction can be used efficiently for the evaluation of selfie addiction in the community and for the research purposes. In addition, it also showed correlation with related psychopathology of the respondent in study population. This scale also covers different domains like narcissistic personality, feeling of self worth, body apperception and body dysmorphic disorder. Ultimately it will help to prevent harmful effects of selfie addiction.

No. 4

Smartphone and Internet Addiction in School Going Children and Associated Psychopathologies

Poster Presenter: Awadhesh P. Singh Solanki, M.B.B.S.

SUMMARY:

AIMS AND HYPOTHESIS The aim of the study was to find out the effect of smartphone and internet use and its associated psychopathology in school children. BACKGROUND Smartphone and internet use among school going children have increased exponentially and its effects on school going children were rarely explored before. METHOD A total of 511 school students from class 1-12 from different urban schools of Kolkata were included in this study from February 2015 to January 2016 to complete a set of questionnaires including demographic details, smartphone addiction scale short version, internet addiction test, teacher's and self-version of Strength and difficulty questionnaire (SDQ). The participants consisted of 413 boys and 98 girls; with ages ranging from 6 to 18 years (Mean=10.81, SD=1.8 years). For measuring the difference between various socio-demographic, clinical & neuropsychological variables, chi square, ANOVA and t-Tests were applied. Spearman's correlation coefficient was used to determine correlation, if any, between the variables. RESULTS Total 25.2% school going children were found addicted to smartphones and 27.8% were moderate and severe internet users. Students

who were having smartphone addiction were having poor grades, significantly higher emotional and conduct problems, more hyperactive and having peer relationships problems, low poor prosocial scores and they were less social and less interactive with others. Overall they were having more difficulties and negative impact of smartphone in their lives. Internet and smartphone addiction both are significantly correlated with each other as smartphone is providing easy internet interface and most of the apps are based on internet connectivity and providing virtual social platform. Children of class 1st to 5th who were having both working parents were having higher smartphone addiction rate. CONCLUSIONS Ultimately this study has shown that excessive smartphone and internet use in children should be monitored and this is a myth that smartphone is making our children smarter. On the contrary it causes scholastic performance deterioration, poor peer interaction and psychopathology. Working parents don't have time to monitor their children, internet and smartphone use due to work pressure and they feel convenient as child doesn't disturb them when they are busy with work which needs to be dealt with.

No. 5

Marijuana Laced With Embalming Fluid Causing Seizures: Is Formaldehyde the Culprit?

Poster Presenter: Bishara Bhasi, M.D.
Co-Author: Najeeb U. Hussain, M.D.

SUMMARY:

Marijuana laced with embalming fluid causing seizures: Is formaldehyde the culprit? Co authors Bishara Bhasi, MD; Najeeb Hussain, MD Abstract: 26 year old female with a past psychiatric history of schizophrenia and cannabis use disorder and no prior history of seizure disorder, who presented with multiple Emergency Room (ER) visits (total of 5) for multiple episodes of seizures in 1 week. During the patient's second ER visit, the patient was found on the streets, confused and was brought in by EMS, who noted that the patient may have been "smoking something". Patient admitted only to smoking cannabis, initially. Patient subsequently had a witnessed, generalized tonic-clonic seizure in the ER, sustained a lip bite, and had postictal confusion. Patient was admitted to the observation unit and neurology team was consulted. CT and MRI showed no acute changes or intracranial space occupying lesions. EEG showed diffuse slowing, without any epileptiform activity. Patient was started on antiepileptic drugs. She had no further episodes of seizures during the hospitalizations and was discharged home. Patient returned the same day, with another episode of seizure, which was attributed to seizure medication non-compliance at that time. Patient was loaded with the antiepileptic drug and discharged home. She subsequently presented to the ER with seizures, twice the next day, despite therapeutic blood levels of the antiepileptic drug. Psychiatry was consulted at that time. Patient then admitted to smoking marijuana laced with embalming fluid each time on her way back home, after discharge. During the multiple ER visits, patient's urine drug screen was consistently only positive for Cannabinoids and never for PCP. Patient was calm, cooperative and didn't show any signs of agitation, other than mild irritability on examination. She reported feeling like she was "stuck" and "couldn't move at times" and also explained that her joints felt hyperflexible at times. Marijuana laced with embalming fluid is a drug that has been around for centuries, however it has been gaining popularity lately. The contents of embalming fluid include formaldehyde, methanol and may also contain PCP, all of which may cause seizures at toxic levels. Urine drug screens usually detect PCP at a level more than 25 ng/ml. Furthermore, PCP causes seizures at levels more than 100 ng/ml. In the absence of PCP in Urine drug screen in the patient, it is unlikely that PCP is the main cause for the seizures. The absence of metabolic acidosis in the patient, also precludes methanol toxicity from being the main cause of the seizures. In this poster, we discuss the challenges of recognizing embalming fluid abuse and subsequent seizures and hypothesize the likely cause to be formaldehyde, a potent neurotoxin, in the embalming fluid.

No. 6

Caffeine-Induced Psychosis in a Bodybuilder With Chronic Testosterone and Amphetamine/Dextroamphetamine Misuse: A Case Report

Poster Presenter: Camila Albuquerque De Brito Gomes, M.D.

Co-Author: Yassir Osama Mahgoub, M.D.

SUMMARY:
Introduction:Caffeine is the world's most consumed psychoactive substance. It is also considered a performance-enhancing substance by some bodybuilders and is, sometimes, excessively used for this purpose. Caffeine's action on adenosine and dopamine receptors is well known, but many other studies reveal its action on testosterone and cortisol, and its possible implication with psychosis. We describe a case of brief psychotic episode following acute, excessive caffeine intake in a body builder with chronic testosterone and amphetamine/dextroamphetamine misuse. Methods:PubMed search for "caffeine", "psychosis", "Adderall", "testosterone", and "cortisol", and an unique case summary. Case report:48 year-old male, bodybuilder, with no medical or psychiatric history, admitted for new onset psychosis, with delusions of being able to predict the death of high profile government officials. He linked his predictions to religion, major astrological events, and developed interest in numerology science, which was out of character for him. He posted his beliefs on social media, which led to Secret Service involvement followed by psychiatric hospitalization. Prior to this episode, he was using unknown amounts of non-prescribed testosterone and amphetamine/dextroamphetamine 60mg daily as performance-enhancing substance in cyclical fashion, for 7 months each year, for the last 4 years. There was no past history of psychosis or any other psychiatric disorder, despite his regular misuse of testosterone and amphetamine/dextroamphetamine. He reported finishing his last cycle of the mentioned substances, a few days prior to his psychosis emergence. This was followed by an increased amount of caffeine ingestion, drinking a minimum of seven espressos each morning (?560mg of caffeine), instead of his usual one daily cup (?80mg of caffeine). His urine toxicology on admission was positive for amphetamines. His psychosis resolved 5 days later, without antipsychotics, as per patient's choice. He was discharged home with secret service notification, outpatient follow up and strong recommendations against using the above combination. Discussion:Several performance-enhancing substances have been implicated with psychosis and mood disorders, such as anabolic steroids, and amphetemine/dextroamphetamine. Although those substances have been reported to cause psychosis independently, our patient was never psychotic despite using them regularly for the last 4 years. There was no recent change in pattern or amount of their use. His psychosis occurred with the recent, excessive caffeine intake, which could possibly cause psychosis by itself or synergistically with another performance-enhancing substance. Conclusion:Caffeine might interact synergistically with other performance-enhancing substances, resulting in increased levels of cortisol and/ or testosterone, and could potentially cause psychosis.

Signing Out Against Medical Advice in a Rehab Setting: A Retrospective Study
Poster Presenter: Charles Rodolphe Odom, M.D.
Co-Authors: Frozan Walyzada, M.D., Rachael Griffin, Margarita Abramovich, Kenny Hernandez, Rachel Schoolcraft

SUMMARY:
Background: Discharge against medical advice (AMA) occurs when a patient chooses to leave before the treating physician has recommended discharge. Patients who leave AMA often present with challenging care as they are more likely to have worse outcomes and are rehospitalized more often than patients who complete treatment (Pages et al ; 1998). Studies have consistently demonstrated that patients who suffer from substance abuse are more likely to leave AMA (Jeffer; 1993). Between 6% and 35% of psychiatric patients discharged themselves from hospital AMA (Dalrymple ; 1993). Few studies have been done which analyze the reasons for AMA in an addiction rehabilitation setting. A study conducted by Lekas et al examined the role of patient-provider interactions contributing to AMA discharge. Inadequate pain management, dissatisfaction with medical care, hospital fatigue (defined as a longing to return to one's home), and everyday life issues were significant factors contributing to AMA in a general hospital setting.

Methods: We will review retrospectively the charts from an in-patient rehab setting in an underserved area between July 2015 to June 2017 to identify the reasons patients sign out AMA and assess correlations to substance abuse, demographics, psychiatric, and medical comorbidities. Conclusion: This retrospective analysis aims to investigate, as well as understand, the influence of patient provider encounter on Rehab AMA discharges. We hope to enhance the development of interventions to prevent AMA, thereby improving patient outcome, promoting retention in an addiction rehab program, and increasing cost effectiveness of treatment.

No. 9

Mind Over Substance? The Role of Mindfulness-Based Interventions in Treating Substance Use Disorders

Poster Presenter: Claire Sathe
Co-Author: Rashi Aggarwal, M.D.

SUMMARY:

Objective: Many patients with a substance use disorder (SUD) fail to achieve long-term recovery with standard pharmacological and behavioral approaches. As a result, the research is increasingly turning to alternative therapies, including mindfulness-based interventions (MBIs). MBIs focus on developing patients' non-judgmental awareness of present experience so that they recognize cognitive or affective states that have previously triggered relapse and avoid the habitual response of substance use. This literature review examines studies that have investigated the effectiveness of MBIs in the treatment of SUDs. Method: Literature review was done on PubMed by using the keywords "mindfulness" and "substance use disorder" or "addiction." We limited our research to English language publications. Results: 28 studies were reviewed, including 23 primary studies and 5 secondary analyses. Of the 23 primary studies, 16 were randomized controlled trials. Participants were affected by SUDs involving illicit drugs, alcohol, and/or tobacco. MBIs tested ranged from a brief mindfulness-based instruction to weekly group sessions over several months. Importantly, many of the studies suffer from major limitations, including small sample size, high attrition rates, and lack of long-term follow-up. The vast majority of the studies found that MBIs were effective either in decreasing cravings, reducing substance use, or preventing relapse after abstinence. Several studies also found a positive relationship between MBIs and markers of mental health in SUD patients such as decreased stress and increased social functioning. Some studies found that the positive impact of MBIs was more pronounced for ethnic or racial minorities and women, perhaps due to the individualized and experiential focus of MBIs. A few of the studies reviewed showed limited or no efficacy of MBIs in treating SUDs. In one study, the benefits of MBIs were restricted to patients with co-occurring psychiatric conditions. Another study found that the MBI tested did not affect abstinence rate for smokers, though it did increase chances of recovery after a lapse. A single study found that the MBI tested was less effective than a distraction-based strategy at reducing cravings of alcohol-dependent participants. However, the MBI tested in this study consisted in a brief mindfulness-based instruction designed as an acute-setting coping strategy. By contrast, a running theme throughout many studies is that frequent formal practice at home is key to maximizing the benefits of MBIs, which tend to develop over time. Conclusion: Numerous studies suggest that MBIs could become a promising new avenue to supplement current pharmacological and behavioral treatments for SUDs. However, a wide range of MBIs was investigated in those studies, with varying outcomes. Further studies would be required to confirm the benefits of MBIs and to assess which types of MBIs are most effective in promoting long-term recovery.

Measures Undertaken at the University of Maryland Medical System in Response to the Opioid Endemic in Baltimore

Poster Presenter: Dileep Sreedharan, D.O.
Co-Authors: Mariam Elizabeth Faris, D.O., Lauren Laddaran, D.O., Avinash Ramprashad, M.D., Eric Weintraub, M.D., Christopher J. Welsh, M.D.

SUMMARY:

The US is in the midst of an opioid epidemic. More than 30,000 people have died from prescription and illicit opioid overdose in 2015. In Maryland alone, between 2015 and 2016, the number of heroin

related deaths increased by 62% (1212 deaths), prescription opioid related deaths increased by 19% (418 deaths) and fentanyl-related deaths increased by 76% (1119 deaths). The city of Baltimore has witnessed a dramatic surge in opioid related deaths in recent years. This poster describes three different programs that have been initiated at the UMMS in response to the opioid epidemic. The goal of these programs is to engage opioid dependent patients in the Emergency Department (ED) in substance abuse treatment. These include the Screening, Brief Intervention, and Referral to Treatment (SBIRT) project, an ED buprenorphine initiative, and a buprenorphine bridge clinic. An SBIRT program for ED patients is a city-wide initiative, utilizing peer recovery coaches with the intent of screening and providing interventions to all adult ED patients who are at risk for substance use. Once evaluated, these patients are referred to treatment and are closely followed up. While SBIRT has been demonstrated to be effective in certain populations, a recent report showed that SBIRT alone was only marginally effective in patients with severe substance use disorders in the ED setting. Subsequently, UMMS developed a protocol that utilizes early initiation of pharmacotherapy (buprenorphine) for patients with opioid dependence. Emerging literature demonstrated that ED initiated buprenorphine treatment was found to significantly decrease opioid use and increase engagement in outpatient substance abuse treatment. Hence, an initiative was undertaken at UMMS to train ED physicians to identify appropriate patients and begin buprenorphine induction in the ED. Using an algorithm developed by substance abuse specialists, the ED physicians are provided access to inclusion and exclusion criteria, recommended laboratory tests, dosing, and potential side effects including precipitated withdrawal. Finally, in conjunction with the Psychiatric Emergency Services (PES), a buprenorphine bridge clinic was developed to address the significant shortage of community providers able and willing to immediately treat patients with opioid agonist therapy. The bridge clinic allows patients to receive continued opioid agonist treatment in the period between ER visit and outpatient intake, thus increasing the likelihood of successfully engaging in treatment. Working in Baltimore has given us the opportunity to gain ample clinical experience working with individuals with opioid use disorders and have helped us identify some innovative strategies for engaging these individuals in treatment. We will provide data and guidelines for the identification, intervention, and treatment of opioid use disorder in the ED setting based upon these three initiatives that have been put into place at UMMS.

No. 11

Prevalence of Substance Use Disorders in a Psychogeriatric Outpatient Clinic

Poster Presenter: Erika Maynard, M.D.

SUMMARY:

Prevalence of Substance Use Disorders in a Psychogeriatric Outpatient Clinic Dr. Erika Maynard, MD Leah Stalnaker, MSIV Dr. Ruthie Cooper, MD Mallory Morris, MSIV Henry Heisy, MSIV Dr. Suzanne Holroyd, MD The purpose of this study was to determine the prevalence of substance use disorders- specifically disorders involving alcohol, narcotics, benzodiazepines, marijuana, and stimulants as well as caffeine and tobacco - in a geriatric psychiatry outpatient clinic population. As the baby boom generation ages, the number of geriatric patients will increase from 40.3 million to 72.1 million between 2010 and 2030. The hope of collecting and presenting this data is that physicians will be better prepared to detect and treat substance use disorders in the growing geriatric population, as they can increase the risk for both medical and psychiatric morbidity. There is a dearth of literature regarding substance abuse among older adults. There are likely several reasons for this, including generational stereotyping, discomfort, inaccurate self-reporting, and misinterpretation of physical symptoms as normal consequences of aging. However, the United States geriatric population is known to have the highest rate of substance use disorder of the developed countries, and the aging baby boom generation has a higher prevalence of substance use than prior generations. In previous years, alcohol use disorder has been the most prevalent substance use disorder amongst older adults, however, it is unclear whether this has changed as the rate of opiate addiction in the United States continues to rise. In this study, 200 patients ages 60 and above who were treated in an

outpatient psychogeriatric clinic were examined by retrospective chart review for presence of substance use disorders. Demographic and clinical variables were also collected including age, sex, race, education level, living arrangements, prescribed controlled substances, mental status exam scores, comorbid medical conditions and comorbid psychiatric conditions. Data was entered into SPSS and examined. Results are presented and discussed, especially as they related to the existing known literature.

No. 12

Opioid-Induced Catatonia in a Middle-Aged Woman: Case Report and Literature Review

Poster Presenter: Fabrizzio A. Delgado, M.D.
Co-Author: Maria Velasco

SUMMARY:

The case we present is of a 40 year old female with history of opioid use disorder who was brought in the emergency department. She was unresponsive to questions, showed signs of waxy flexibility, fixed posturing and catalepsy with Busch and Francis catatonia scale (BFCS) score of 17. Patient had been seen two times previously on the same day because of heroin use and occasional auditory hallucinations. Opiates, methadone and benzodiazepines (after challenge) were positive on urine toxicology. Patient was given lorazepam challenge IM route and the patient became more verbal and responsive to external stimuli. Two hours later patient became agitated, was praying loud, and presented purposeless movements and dancing mannerisms. She was given 2 mg PO of lorazepam was given with little to no effect. 30 minutes later patient continue to be agitated and broke her glasses, she was then given 1MG of lorazepam IM route with resolution of symptoms. Catatonia is a disorder that used to be described as rare. Prospective studies at individual psychiatric units describe an incidence ranging from 5-20%. (1) It is characterized by stupor/akinesia, catalepsy, waxy flexibility, mutism, negativism, posturing, mannerisms, stereotypy, agitation, echolalia and echopraxia. (3) Catatonia can be seen as part of a mood or psychotic disorders (2) (4). It can also be secondary to a variety of medical conditions including neurological disorders, infections and metabolic disturbances (5). Catatonia can be also secondary to medications and substances such as corticosteroids, immunosuppressants, clomipramine, antipsychotics, methylphenidate, cocaine, PCP, and as in this case, by high doses of opioids (4, 5,7,9,11). The pathophysiology of Catatonia is complex. It includes alterations in dopamine. Disturbances in serotoninergic, GABA, (4,5) norepinephrine and glutamate systems. Iron channel abnormalities, dysfunction of frontal, neocortical, limbic and even brain stem circuitry are suspected. (8,6) Systemic opioid administration can increase muscle tone and induce muscle rigidity. This is probably related to a catatonic state (7) and is different from the akinetic state with no muscular rigidity produced by injections into the Nucleus Accumbens. This findings suggests interference of at least two different topographic locations involved in the opioid induced akinesia and muscular rigidity of catatonia.(8) In a time when heroin and prescription opioids has increased across the US among men, women, most age groups and all income levels (14) we present a case of a potentially fatal consequence of the use of opioids. The pathophysiology of this disorder is not completely understood and should be a focus of our research. Increased awareness is needed for identification of catatonia and its prompt treatment in this population. Rating scales and screening instruments are reliable and a valid tool that facilitates diagnosis and treatment protocols for catatonia. (13)

No. 13

Anticonvulsants as an Alternative or Adjunct to Treat Alcohol Withdrawal: A Systematic Review

Poster Presenter: Fnu Syeda Arshiya Farheen, M.B.B.S.
Lead Author: Aarti Govind Chhatlani, M.D.
Co-Authors: Madhuri Jakkam Setty, M.B.B.S., Geetha Manikkara, Rajesh R. Tampi, M.D., M.S.

SUMMARY:

Background: There is growing evidence that anticonvulsants are a safe alternative to treat alcohol withdrawal or they may be an appropriate adjunct. Objective: To systematically review literature to evaluate the data available on commonly used anticonvulsants as monotherapy or adjunct to treat alcohol withdrawal. Methods: We

performed a literature search of Pubmed, PsychINFO, MEDLINE and Cochran databases through 31 August 2016, using the following keywords: “alcohol withdrawal”, “valproate”, “gabapentin”, “lamotrigine”, “carbamazepine” and “oxcarbazepine”. The search was not restricted by language but in the final analysis only studies that were published in English or had official English translations were included. Results: The systematic review of literature identified a total of 23 double blind randomized controlled trials that evaluated the use of anticonvulsants in treatment of alcohol withdrawal. Of these studies, seven focused on patients in outpatient setting. While sixteen studies focused on patients that were admitted and four studies did not specify the setting. According to the literature, anticonvulsants are just as effective as sedatives/hypnotics in treating mild or moderate alcohol withdrawal symptoms. Six studies evaluated the use of anticonvulsants as adjuncts to sedatives/hypnotics. Combining anticonvulsants with sedatives decreases the quantity of sedatives required to treat withdrawal symptoms and the symptoms resolve quicker. There is some data that gabapentin, valproate and carbamazepine can be used to treat alcohol withdrawals as monotherapies. In addition, 20 of these studies looked at adverse effects. In one study patients experienced drug adverse effects and the study was terminated. In most studies, drop-out rates due to severe withdrawal or adverse effects were similar between control and anticonvulsant groups. The remaining studies identified minor adverse effects. Conclusion: Anticonvulsants have good efficacy as monotherapy and as adjuncts with sedatives /hypnotics in treating mild to moderate alcohol withdrawal syndrome. Anticonvulsants have less adverse effects and addiction potential compared to sedatives/hypnotics.

No. 14

Heroin-Induced Leukoencephalopathy: A Case Report and Literature Review

Poster Presenter: Fnu Syeda Arshiya Farheen, M.B.B.S.

Co-Authors: Juan Joseph Young, M.D., Rajesh R. Tampi, M.D., M.S., Venkatesh Sreeram, Ngu Aung

SUMMARY:

Objective: Toxic leukoencephalopathy is a rare neurologic disease. Our aim is to inform the cognitive and behavioral disturbance associated with toxic leukoencephalopathy [TLE] and heroin use along with imaging findings in a middle-aged woman. Design: Case report. Case presentation: A 49-year-old Caucasian women with history of Major Depressive Disorder, Post-Traumatic Stress Disorder, Generalized Anxiety Disorder and Heroin use disorder (sniffing heroin for more than 20 years) was admitted for altered mental status. She was disoriented with dissociative symptoms, impoverished thought content, blunted affect and distractibility. During her stay she was minimally responsive, stayed isolative and displayed bizarre behavior, was refusing food and fluid intake. Initially she was considered as in delirious state due to infectious etiology, as her urinalysis was positive for Leukocyte esterase and head Computed Tomography (CT) was normal, which later confirmed negative with urine culture and other labs including blood and cerebrospinal fluid (CSF) cell count and culture. She was also tested negative for other infectious pathologies including Hepatitis, Syphilis and Human Immunodeficiency Virus (HIV). Her magnetic resonance imaging (MRI) brain showed white matter lesions (Mild but diffused signal abnormality in the deep supratentorial white matter with mild diffusion restriction). She was admitted for 9 days with improvement in orientation, mood and spontaneous speech, but remained disorganized and paranoid in behavior. Discussion: TLE is an uncommon complication with heroin abuse. Inhalational heroin use by heating the drug has been studied as an implication in TLE, which typically termed as “Chasing the dragon” with first case identified in 1982. Few case reports reported the dose of heroin attained with inhalation is high, while few studies claimed heating produces a mediate toxic compound that cause TLE. TLE is characterized with deficits involving motor and cerebellar pathways, especially posterior limb of internal capsule involvement and spongiform myelinopathy with fluid overload in myelin sheaths. TLE that occur rarely with exclusion of cerebellar and brain stem involvement in cocaine abusers, reported better prognosis. Literature suggests the association of intravenous heroin with Hypoxic Ischemic Encephalopathy (HIE). While HIE is frequently

associated with gray matter changes in MRI, whereas no such involvement elicited in TLE. Coenzyme Q and other antioxidant therapy has been studied to demonstrate clinical improvement according to the literature. Conclusion: Toxic leucoencephalopathy associated with inhalational heroin use has been studied as rare, but has poor prognosis. The etiology and pathophysiology involved is poorly understood. We need more RCTs and Systematic reviews to understand the pathophysiology and to help with timely management of this debilitating neurological condition.

No. 15

Use of Cariprazine (Vrylar) in Psychiatric Disorders: Systematic Review

Poster Presenter: Fnu Syeda Arshiya Farheen, M.B.B.S.

Co-Authors: Aarti Govind Chhatlani, M.D., Madhuri Jakkam Setty, M.B.B.S., Geetha Manikkara, Rajesh R. Tampi, M.D., M.S.

SUMMARY:

Introduction: Cariprazine is a new, novel, atypical antipsychotic agent with Dopamine D2 and D3 partial agonist effects recently approved for treating schizophrenia, bipolar mania and in clinical trial phase 2 for depression in the USA. Objective: The purpose of this review is to systematically review literature to evaluate the safety and efficacy of cariprazine in psychiatric disorders (Schizophrenia, bipolar disorders, depression) in comparison with a placebo. Methods: We performed a literature search of PubMed, MEDLINE, EMBASE, PsycINFO and Cochrane collaboration databases through 31 August, 2016 using the following keywords: “cariprazine”, “depression”, “schizophrenia” and “bipolar disorder”. The search was not restricted by the age of the patients or the language of the study. However, in the final analysis the studies involving patients that were published in English or had official English translations were included. In addition, we reviewed the bibliographic databases of published articles for additional studies. Results: The systematic review of literature identified a total of 9 articles that evaluated the use of cariprazine in treatment of psychiatric disorders. There were 8 double blinded randomized controlled trials and 1 was analyses of pooled data from phase II/III trials; of these 50% were phase III trials (n=4) and phase II trials (n=4). Four of these evaluated the safety and efficacy of Cariprazine in Bipolar I depression, one investigated its use as an adjunct to antidepressants in Major depressive disorder (MDD) and three evaluated its use in treatment of acute exacerbation of Schizophrenia. Two studies used risperidone or aripiprazole as comparators in addition to placebo. Both low- and high-dose cariprazine were more effective than placebo in the treatment of acute manic or mixed episodes associated with bipolar I disorder and also Schizophrenia. As an adjunctive treatment, it showed efficacy in treatment of MDD patients as measured by change in MADRS total score. However, patients were selected based on inadequate antidepressant response, these results may not be generalized to all patients with MDD. The main cause of study discontinuation was mania or akathesia. Side effects were similar in all studies evaluated. Conclusions: This review has demonstrated modest safety, superior efficacy and good tolerability of cariprazine in treating psychosis, mania, and depression at both low and high dose in comparison to placebo. Cariprazine was generally well tolerated, however EPS-related treatment emergent adverse events were more common than with placebo particularly the incidence of akathisia was greater with cariprazine than with placebo

Hallucinations as a Side Effect of Mirtazapine: A Case Report and Literature Review

Poster Presenter: Alexandra Berliner, M.D.

Co-Authors: Rashi Aggarwal, M.D., Tamkeen Khurshid, M.B.B.S.

SUMMARY:

Introduction: Mirtazapine is a commonly used antidepressant with a relatively safe side effect profile. Among all the side effects listed, hallucinations are an uncommon side effect that is relatively unknown. Here we describe our patient and review of the relevant literature. Case: We present a case of a 92 year old woman without any prior psychiatric history who initially presented to the hospital complaining of a tremor and muscle spasm in all 4 extremities that began several weeks ago. After an extensive work up, it was presumed to

be related to anxiety. In the outpatient clinic, she was started on mirtazapine 7.5 mg PO at bedtime. Patient developed new onset of visual hallucinations after the second dose of mirtazapine, which included visualizing crawling insects. Family noted that she appeared to be “pulling on strings” and waving things away from her. She continued to take mirtazapine for a total of 4 days prior to stopping as the hallucinations have worsened. Hallucinations began improving upon discontinuation of mirtazapine and fully resolved on the 3rd day of discontinuation. Results: Three other cases were reported in the literature, all the cases were in older patients (age >58). The hallucinations fully resolved once mirtazapine was either lowered in dose or discontinued. This case, along with the cases reviewed, suggests a relationship between mirtazapine use and development of hallucinations. The appearance of hallucinations directly after initiation of mirtazapine and the prompt resolution of hallucinations after drug discontinuation, led to the impression that this was a drug-induced phenomena. Mirtazapine is a tetracyclic antidepressant with noradrenergic and serotonergic activity. Mirtazapine also blocks histamine H1 receptors, which leads to sedation. It has also been shown that treatment with mirtazapine increases the dopamine levels in the frontal cortex, as a result of alpha2-adrenergic blockade. The exact pathophysiology of mirtazapine induced hallucinations remains unknown. Three hypotheses have been postulated in an attempt to explain the side effect. One hypothesis is the serotonergic delirium hypothesis, which is unlikely since none of the patients met the criteria for serotonin syndrome. Another hypothesis is the norepinephrine oversensitivity hypothesis and the last is the dopaminergic hypothesis. Oversensitivity to acute increases of norepinephrine following mirtazapine initiation is a possible explanation as centrally increased norepinephrine has been observed in certain types of delirium. Dopamine is a likely contributor to hallucinations as evidenced by the dopamine receptors playing a role in pathophysiology of schizophrenia. Discussion: The relative tolerability of mirtazapine, along with its side effect profile, makes it a first line medication for treating depression in elderly patients. Although uncommon, hallucinations can be a side effect of mirtazapine that patients and providers should become aware o

No. 17

Dose-Depedendent Duloxetine Hepatotoxicity: A Case of Idiosyncratic Drug-Induced Liver Injury

Poster Presenter: Areef S. Kassam, M.D.
Co-Author: Elizabeth Cunningham

SUMMARY:

Introduction: Duloxetine (Cymbalta®) inhibits the re-uptake of both serotonin and norepinephrine and is FDA approved for major depressive disorder, diabetic neuropathy, fibromyalgia, chronic musculoskeletal pain, and generalized anxiety disorder. While cases of hepatotoxicity with duloxetine have been documented, none have demonstrated a dose-dependent relationship. Objectives: The primary objective is to describe a case of drug-induced liver injury after a dosage increase of duloxetine. Case Discussion: We present a case of a 37 year old female with Major Depressive Disorder, Alcohol Use Disorder, and Opioid Use Disorder presenting with a depressive episode. She was started on duloxetine 40 mg daily then increased to 60mg in order to target residual depressive symptoms. Twenty four hours later, she had significant anxiety, bilateral tremor, hyperthermia, and autonomic instability. Physical exam was remarkable for right upper quadrant tenderness. Tests for viral hepatitis and auto-antibodies were negative. Table 1: Liver Function Tests Total Bilirubin Alkaline Phosphatase AST ALT Reference Range 0.1-1.2 mg/dL 38-126 U/L 17-59 U/L 11-58 U/L Baseline 0.4 mg/dL 57 U/L 20 U/L 12 U/L At Symptom Onset (A) 0.4 mg/dL 105 U/L 203 U/L 156 U/L 2 days after Discontinuation (B) 0.2 mg/dL 101 U/L 49 U/L 93 U/L 7 days after Discontinuation (C) 0.3mg/dL 83 U/L 25-37 U/L 37U/L The patient’s initial lab work revealed normal liver function tests upon admission (Table 1). All medications were held and the patient was given a normal saline bolus. Subsequently, the patient showed improvement of physical symptoms. Symptoms fully resolved and laboratory markers returned to baseline within one week of duloxetine discontinuation. Conclusion: This case offers an example of acute drug-induced liver injury occurring after a dosage increase of duloxetine. The onset of

symptoms and elevation in enzymes following a duloxetine dose increase support the etiology of a dose-dependent drug-induced liver injury in this patient.

No. 18

Assessment of Metabolic Syndrome in Patients Experiencing First-Episode Psychosis Treated With Antipsychotics

Poster Presenter: Ariba Shah

SUMMARY:

Although antipsychotic medications have been shown to affect lipid and glucose metabolism and a need for early monitoring has been identified, Canadian data on the metabolic side effects of antipsychotics in young patients in the early phase is scarce. The aim of this study was to quantify the risk of metabolic syndrome development over the initial 1-2 years of antipsychotic treatment in patients experiencing a first episode of psychosis and to examine adherence to metabolic screening in a real-world EPI program. We conducted a retrospective chart review of 52 patients, 14-35 years old, admitted to the Early Psychosis Intervention Program at Hotel Dieu Hospital, in Kingston, ON, Canada, from 2009-2016. This clinic has a multidisciplinary approach to care, with patients being followed up by an individually assigned case manager, clinic nurse and psychologist, in addition to a psychiatrist. To be included in our study, patients must have had at least one year of follow up from time of initial visit, and at least two time points where they had all measurements. Data was collected on age, sex, antipsychotic medication, Body Mass Index (BMI), waist circumference (WC), blood pressure (BP), high density lipoprotein (HDL), triglycerides (TG), fasting blood sugar (FBS)/ random glucose (RG), and HbA1C at initial visit, and follow ups at 3, 6, 12, 18, and 24 months. Metabolic Syndrome was defined using the International Diabetes Federation criteria. The percent of patients in this retrospective cohort with metabolic syndrome increased over time: 11%, 19%, 29%, 33%, and 35% at 0, 6, 12, 18, and 24 months respectively. Looking at individual parameters, the percent of patients with high BMI, BP, waist circumference, TG, FBS, and low HDL, all increased over time. Waist circumference showed the biggest increase, with 17.5% of patients having a high waist circumference at baseline and 50% at 24 months. Glycemic control contributed the least towards metabolic syndrome: HbA1C was within target in all patients and RG was high in only two patients at baseline with no change over time. In patients with early psychosis treated with antipsychotics, BMI and WC become abnormal before blood parameters, and, therefore, appear to be cost effective measures to predict the development of metabolic syndrome. Despite their young age, these patients are at high risk of developing metabolic syndrome and subsequent cardiovascular disease, warranting close and early follow-up.

No. 19

A Case of Neuroleptic Malignant Syndrome in the Context of Lithium Toxicity and Aripiprazole Use

Poster Presenter: Autumn Rose Schultz, M.D.
Co-Author: Carolyn Elizabeth Linek-Rajapaksha, M.D.

SUMMARY:

Mr. C, a 60-year-old Hispanic male with active psychiatric diagnoses of bipolar disorder type I and cannabis use disorder was admitted to the psychiatric unit for worsening depression and intermittent suicidal ideation in the context of medication non-compliance. On admission, his outpatient oral aripiprazole was reinitiated and later titrated. The patient continued to show little improvement in his psychomotor retardation, neglect of ADLs, and poor oral intake. He later endorsed psychotic symptoms and therefore, on hospital day 27, lithium was started and titrated for efficacy. Patient began to show some reduction in auditory and visual hallucinations and psychomotor retardation. However, on hospital day 49 the patient was found to have altered mental status (AMS), bilateral upper extremity tremors, disorientation, and worsening psychomotor retardation. Lithium level was found to be supratherapeutic and patient was transferred to the medical ward due to lithium toxicity; lithium administration was held. He continued to display AMS, and was also thought to be catatonic. He failed several lorazepam challenges and had a thorough negative medical workup. Lithium levels became subtherapeutic and lithium was restarted on hospital day 53. He subsequently developed worsened rigidity, autonomic instability

and fevers, leading to concern for neuroleptic malignant syndrome (NMS) despite repeated normal levels of CK. The patient's lithium and aripiprazole were discontinued on hospital day 55. Empiric NMS treatment with bromocriptine and dantrolene were subsequently initiated with resolution of fevers, rigidity, and autonomic derangements. As NMS is a psychiatric emergency with significant morbidity and mortality, understanding the etiology and risk factors as well as early detection are critical to patient outcome. In this poster, we discuss the potential for aripiprazole and lithium to lead to development of NMS.

No. 20

Quetiapine-Associated Neutropenia After Suicide Attempt by Overdose

Poster Presenter: Bartholt Bloomfield-Clagett, M.D.

SUMMARY:

Ms. G, a 78 year old Hispanic female with a past psychiatric history of schizophrenia, presented to the psychiatric consult service after overdose on multiple home medications, including quetiapine, clopidogrel, ranitidine, omeprazole, and acetaminophen. Her hospital course was complicated by severe neutropenia. On admission, her absolute neutrophil count (ANC) was 8000, which decreased to a nadir of 100 after two weeks in the hospital. Ms. G was given 2 doses of granulocyte colony stimulating factor with initial brisk ANC recovery followed by a rapid decline to neutropenic levels. Five weeks after admission, the patient's ANC recovered to greater than 1000. Quetiapine was restarted and the patient's ANC decreased again to less than 800. Quetiapine was discontinued and Ms. G's ANC recovered. While quetiapine associated neutropenia has been reported in the literature previously, this represents the first case of reported quetiapine-associated neutropenia after overdose. In this poster, we provide a review of the literature, including possible mechanisms of quetiapine induced neutropenia. We also discuss the possible benefit of ANC monitoring after antipsychotic overdose and the challenges of antipsychotic treatment for schizophrenia in those with antipsychotic induced neutropenia.

No. 21

Comparing the Effects of Bupropion and Escitalopram on Excessive Internet Game Play in Patients With Major Depressive Disorder

Poster Presenter: Beomwoo Nam

Co-Authors: Inki Sohn, Doug Hyun Han

SUMMARY:

Objective: Several studies have suggested the efficacy of bupropion and escitalopram on reducing the excessive internet game play. We hypothesized that both bupropion and escitalopram would be effective on reducing the severity of depressive symptoms and internet gaming disorder (IGD) symptoms in patients with both major depressive disorder (MDD) and IGD. However, the changes in brain connectivity between the default mode network (DMN) and the salience network were different between bupropion and escitalopram due to their different pharmacodynamics. Methods: This study was designed as a 12-week double blind prospective trial. Thirty patients were recruited for this research (15 bupropion group + 15 escitalopram group). To assess the differential functional connectivity (FC) between the hubs of the DMN and the salience network, we selected 12 regions from the automated anatomical labeling (AAL) in PickAtals software. Results: After drug treatment, the depressive symptoms and IGD symptoms in both groups were improved. Impulsivity and attention symptoms in the bupropion group were significantly decreased, compared to the escitalopram group. After treatment, FC within only the DMN in escitalopram decreased while FC between DMN and salience network in bupropion group decreased. Bupropion was associated with significantly decreased FC within the salience network and between the salience network and the DMN, compared to ecitalopram. Conclusions: Bupropion showed greater effects than escitalopram on reducing impulsivity and attention symptoms. Decreased brain connectivity between the salience network and the DMN appears to be associated with improved excessive IGD symptoms and impulsivity in MDD patients with IGD.

No. 22

Case Report: Hepatoxicity Linked to Chronic Use of Risperidone

Poster Presenter: Brandi Sauer

Co-Author: Caesa Nagpal, M.D.

SUMMARY:
Risperidone is an atypical antipsychotic that is widely used by many physicians in the treatment of Bipolar disorder and Schizophrenia. Use of Risperidone is associated with serum aminotransferase elevations which are mostly mild, transient and mostly occurring within the first 8 weeks of treatment. Some cases of acute liver injury have been reported to occur after months or years of treatment with Risperidone. We report one such case of a 38 year old male who presented with acute exacerbation of psychotic symptoms and was treated with Risperidone and developed increased serum aminotransferase and alkaline phosphatase. Method: (Case Report): Mr. Q, a 38 year old male with previous history of Schizophrenia was admitted to acute psychiatric facility after he was incompetent to stand trial. On admission, he was a poor historian and mostly gave illogical responses to most of the questions asked. The patient's mental status exam was significant for poor hygiene, malodorous, pressured speech, and disorganized thought process. He was seen responding to internal stimuli and frequently seen laughing inappropriately. He was started on Risperidone 4 mg/ day which was increased to 6 mg/ day after 3 days to have a better control of psychotic symptoms. This patient has been on Risperidone for the last 6 months. Routine labs were obtained which showed elevated serum aminotransferases (AST 200/ ALT 398), increased alkaline phosphatase and increased ammonia levels. Hepatitis panel, Serum iron, Serum ferritin, TIBC, Serum Ceruloplasmin, HIV, Vitamin B 12 and folate were negative for any abnormalities. Risperidone was discontinued and was alternately started on Paliperidone to help with psychosis. The serum aminotransferases came back to normal in 10 days after discontinuation of Risperidone. Discussion: Liver test abnormalities can occur up to 30 % of patients with long term use of Risperidone. It is mostly associated with elevated serum aminotransferases and in some rare cases can manifest as autoimmune hepatitis. It is imperative to remember that some psychopharmacological agents are also associated with risk of hepatoxicity. The type of hepatic lesion associated with antipsychotics can follow a primary hepatocellular pattern, therefore the main change in laboratory tests seem to be an elevation in aminotransferases. Hence it is important to get liver function tests when initiating treatment with atypical antipsychotics. Conclusion: Atypical antipsychotics like Risperidone can be associated with hepatoxicity and it is important to get liver function tests before and during treatment with atypical antipsychotics.

No. 23

Clozapine-Induced Myocarditis Following Bacterial Gastroenteritis: The Role of Infection in Clozapine-Mediated Cardiac Events

Poster Presenter: Christian Umfrid, M.D.
Co-Author: Julie B. Penzner, M.D.

SUMMARY:
Mr. G, a 39-year-old Orthodox Jewish man, was admitted to the inpatient psychiatric unit for initiation of clozapine for treatment-refractory schizoaffective disorder. Pre-treatment history and work-up demonstrated that he was medically stable and without contraindications to clozapine administration; he had well-managed hypertension, hyperlipidemia, and hypothyroidism, and had an unremarkable laboratory and cardiac evaluation, including baseline electrocardiogram and echocardiogram. Clozapine was initiated and titrated over the course of two weeks to a therapeutic dose with close monitoring of serum levels, and was well-tolerated by the patient. On day 14 of treatment, he developed constitutional symptoms of fatigue, malaise, accompanied over the following day by fever, nausea, explosive diarrhea and vomiting. His stool was positive for pathogenic enteroaggregative E. coli, indicative of infectious gastroenteritis, likely acquired from contaminated food brought onto the unit. Clozapine was held after symptom onset, and the patient was treated with broad-spectrum antibiotics given an evolving acute kidney injury, rising leukocytosis and fever. Despite improvement of gastrointestinal symptoms, he remained persistently febrile and had elevated cardiac enzymes. The patient's medical status rapidly declined and he required transfer to the intensive care unit, where he was intubated for acute respiratory failure, and was found to be in heart failure (ejection fraction 33% from baseline 62%). Cardiac biopsy confirmed myocarditis, with the likely

etiology being clozapine. This case is remarkable for clozapine-induced myocarditis with acute onset coinciding with a bacterial infection not typically associated with myocarditis. It further contributes to a small number of recently reported cases that have demonstrated an apparent temporal correlation between infection and clozapine-induced myocarditis during drug initiation and titration. Taken together, these cases have begun to suggest a possible synergistic relationship between the immune response to infectious pathogens and to clozapine in the precipitation of myocarditis. Given the complex immunomodulatory actions of clozapine, and the previously demonstrated rise in clozapine serum levels during infection, there exist multiple possible mechanisms of interaction and immunopotentiation that may contribute to the onset of myocarditis and warrant further investigation. Clinically, there is considerable overlap in the early systemic symptoms of infection and myocarditis, complicating recognition of the latter and the rapid discontinuation of clozapine, which is critical to optimizing patient outcome. In this poster, we discuss a hypothesized relationship between gastrointestinal infection and risk of myocarditis during clozapine treatment, potential mechanisms, and the need for vigilance in monitoring for adverse cardiac events throughout the course of infection while a patient is treated with clozapine.

No. 24

Can a PTSD Treatment Cause Physical Trauma? New-Onset Priapism Associated With Prazosin

Poster Presenter: David Roberto De Vela Nagarkatti-Gude, M.D., Ph.D.
Co-Author: Julie C. Anderson, M.D.

SUMMARY:

After engaging in psychotherapy for several months, a 37 year-old male agreed to his therapist's recommendation that he seek psychiatric consultation for adjunctive pharmacotherapy for PTSD. Having limited prior exposure to psychotropic medication, Mr. A preferred to limit his medications but was eager to attain better sleep and relief from trauma-related nightmares, so was willing to trial prazosin. After benefitting from gradual titration to 4mg prazosin over the course of several weeks, the veteran agreed to initiation of duloxetine as well. During the a 2-week period of co-treatment with duloxetine and prazosin (up to 8mg), Mr. A experienced 3 separate episodes of priapism. During the third episode of priapism, he presented to the Emergency Department and required emergent Urology consultation and treatment with irrigation/aspiration and phenylephrine. Prazosin was stopped, duloxetine was continued, and the patient continued without further episodes or priapism throughout the period of follow up. In this poster, we consider the variety of dosing paradigms that have been suggested, examine literature suggesting that anti-adrenergic medications may all carry a risk for the serious adverse effect of priapism, and discuss whether factors in medication dose and titration schedule may affect risk.

No. 25

Valproic Acid-Induced Necrotizing Pancreatitis: A Case Report and Literature Review

Poster Presenter: Deepika Sundararaj, M.D.
Co-Author: Walter Kilpatrick

SUMMARY:

Background: Acute pancreatitis is an established but poorly recognized side effect of treatment with valproic acid (VPA). Multiple case reports have been published analyzing the correlation between valproic acid and acute pancreatitis. Norgaard et al, performed a population-based case-control study in Denmark analyzing valproic acid as an independent risk factor for acute pancreatitis. However, necrotizing pancreatitis may be an even rarer side effect associated with valproic acid. Our literature review revealed only one case report describing it. Method: Initial lab work showed elevated lipase of 1000 with amylase of 708. As part of his sepsis work up, a CT abdomen was done which showed progressive pancreatitis with hypoenhancing areas in the body and tail suggesting necrosis. RUQ ultrasound was negative for gallstones or biliary dilatation. Results: Our case describes a 70-year-old male who presented after 48-hours of decreased PO intake and worsening abdominal pain. He decompensated and was admitted to the ICU with necrotizing pancreatitis. As he did not have risk factors for other more prevalent causes of pancreatitis, it was determined his etiology was related to his VPA treatment. Psychiatry was

consulted to recommend alternate medication management for patient's bipolar disorder. At our initial consult, we determined the patent had been treated with VPA for at least 10 years. He was started on gabapentin and lithium. The patient eventually stabilized and was transferred to the regular medicine floor. Unfortunately due to his deconditioning, he required PEG tube, but placement was made difficult due to his pathology. Ultimately he decompensated further and was made CMO and discharged to hospice care. Discussion: There have been multiple case reports of acute pancreatitis associated with VPA. Our literature review found only one case report discussing necrotizing pancreatitis associated with VPA use. To our knowledge, this is only the 2nd case of necrotizing pancreatitis reported secondary to VPA. Conclusion: Clinicians need to be aware of the potential long-term effects of treatment with VPA including rare sequelae of necrotizing pancreatitis in order to safely treat and monitor patients utilizing this medication.

No. 26

Application of Novel Approaches for the Design of a Venlafaxine Efficacy Prediction Model

Poster Presenter: Dekel Taliaz

SUMMARY:

To date, the gold standard used to determine patient response to antidepressant treatment is a depression score improvement of 50% or greater from the initial score. However, this definition does not take into account the 'time to response' different individuals exhibit, therefore not allowing for any differentiation between response rates. By taking into consideration both depression scores, and time to response, new features can be identified that may serve as predictors. In addition, not necessarily a single polymorphism, but rather combinations of genetic variations may impact the efficacy to antidepressants. We applied novel methods, to design a prediction model of efficacy to Venlafaxine treatment. First, we designed a response model for Venlafaxine treatment based on the raw data of the Sequence Treatment Alternatives to Relieve Depression (STAR*D) clinical trial. Second, we applied a genome- wide association approach for genetic feature selection, and then we developed a prediction model by applying machine learning algorithms to define combinations of parameters that predict response for Venlafaxine. The following results were obtained: Area Under the Curve of 0.8511, accuracy of 77.50%, sensitivity of 76.19% and specificity of 78.95%. The use of different response models and machine learning algorithms allowed us to design a highly accurate prediction model of response to Venlafaxine. Applying new models and new algorithmic methods on currently available large datasets can lead to novel findings which will advance our understanding of psychiatric disorders, and advance the design of accurate prediction models for psychiatric medications.

No. 27

Adverse Outcomes in Switching From Brand-Name to Generic Desvenlafaxine

Poster Presenter: Elena Jordan

Co-Authors: Jeannie D. Lochhead, M.D., Adam Mathew Basiago, Michele A. Nelson, M.D., Gerald Maguire

SUMMARY:

Major depressive disorder (MDD) is the world's leading cause of disability. It affects approximately 300 million people, and is a major risk factor for suicide with close to 800,000 deaths per year due to suicide. Selective serotonin reuptake inhibitors (SSRIs) are an effective treatment, but some patients do not reach remission with an SSRI. These patients may benefit from treatment with a selective norepinephrine reuptake inhibitors (SNRI), such as desvenlafaxine. We report a series of cases of patients who were in remission from MDD, but whose symptoms returned upon switching from brand name Pristiq to generic desvenlafaxine. This case series lends support to previous reports that some psychiatric patients are more successfully treated with a name brand medication, and raises the question of differences in generics and brand name medications. Multiple factors might explain this. Generic medications do not undergo the same stringent approval process that name brands require. There are not the large clinical trials needed by name-brands, and instead generics are approved based on bioequivalence studies. Bioequivalence is used to determine whether a brand name and

generic have the same efficacy and is determined by comparing the bioavailability, the area-under-the-curve on the drug concentration-time curve (AUC), as well as the maximum plasma concentration of the drug. Importantly, bioequivalence studies are generally performed on homogenous small groups of male, healthy volunteers and regulating agencies (FDA) require that a generic have only an 80% to 125% bioequivalence of its name brand counterpart This means there is room for generics to be potentially less effective than name brand equivalents, especially when certain subcategories are taken into account.

No. 28

A Case of Extrapyramidal Symptoms With the Co-Administration of Aripiprazole and Paroxetine

Poster Presenter: Eliza Buelt, M.D.

SUMMARY:

Background Aripiprazole is a second generation antipsychotic that is a partial agonist at dopamine D2 and serotonin 5-HT1A receptors and an antagonist at serotonin 5-HT2A receptors. It is metabolized to its active metabolite dehydroaripiprazole by cytochrome (CYP) 2D6 and CYP3A4. Paroxetine is a selective serotonin reuptake inhibitor and is a potent CYP2D6 inhibitor. Paroxetine has been shown to increase aripiprazole levels in a dose-dependent manner.1 This case illustrates side effects with the co-administration of these medications. Case A 24-year-old woman with a history of schizoaffective disorder, depressive type presented to the Emergency Department complaining of bilateral hand tremor, stiffness, drooling, and restlessness. Her symptoms developed a month after a hospitalization following a suicide attempt in the setting of paranoid psychosis. She was discharged on aripiprazole 15 mg BID and paroxetine 40 mg daily. On exam, she was noted to have mydriatic pupils and tremor in her bilateral hands, tongue, and lips. She maintained an uncomfortable appearing upright posture, had cogwheel rigidity in bilateral upper extremities, and decreased arm swing on her gait. Creatine phosphokinase and serum iron levels were checked due to concern for neuroleptic malignant syndrome and were normal. She was admitted to the inpatient psychiatric unit. Initially, paroxetine was decreased by half and aripiprazole was held. She was also started on benztropine 0.5 mg BID. Her cogwheel rigidity and tremor improved. Aripiprazole was restarted at a lower dose prior to discharge. Discussion Second generation antipsychotics medications and antidepressants are commonly co-prescribed in clinical practice. Even small doses of paroxetine have been shown to increase aripiprazole levels, and in this case the patient presented with extrapyramidal symptoms and akathisia. Clinicians should be aware of common drug-drug interactions and the potential for adverse effects. Additionally, although genetic testing was not performed in this case there is significant polymorphism in the CYP2D6 gene and other cytochromes which may influence proneness to adverse effects.2

No. 29

The Use of Long-Acting Injectable (LAI) Antipsychotics in Greece: Physicians' Beliefs and LAIs Use in Clinical Practice

Poster Presenter: Fotiadis Petros

SUMMARY:

Background/ Aim: Treatment goals of patients with schizophrenia have recently been raised – improvement and maintenance of functionality is nowadays in focus, in line with relapse prevention and long term symptom control. Long acting injectable antipsychotics (LAIs), especially early in the disease course at the time when functionality is most important to be preserved, is considered to be a valid treatment option, although very often underutilized. The aim of this observational questionnaire-based study was to evaluate the % of LAIs usage in clinical practice in Greece and investigate its correlation with physicians' beliefs. Methods: Questionnaires were distributed to psychiatrists in 3 PanHellenic Conferences in 2015-2016. One Way Analysis of Variance was used as the main statistical evaluation tool as well as paired samples t-test when comparisons were made between mean values. Results: This analysis included 98 questionnaires filled in by psychiatrists in Greece. 76,5% of the responding psychiatrists are practicing in the 2 big cities, Athens and Thessaloniki, 50% are practicing 6-15 years and 45% of them have only private practices. Preliminary data concerning the psychiatrists' perception showed that 50% of the

sample recommend a LAI after the first relapse and almost 1 out of 5 that their first LAI recommendation is only after the 2nd relapse. When evaluating the positive LAI features, it seems that psychiatrists in Greece are convinced that "LAIs are as effective as oral formulations" (4.6/5±0.6) whereas they do not believe that "LAIs are easy to titrate" (3.7/5±1.3). The benefits of LAIs that psychiatrists reported in the questionnaires in frequency order were: increased compliance, relapse prevention, treatment control, less adverse events and treatment coverage. The problems that were also reported were: increased duration of adverse events, cost, fear of needles, invasive method and difficulty of applying the injection. In a scale from 1-5 (1=no awareness, 5=excellent knowledge), the physicians' knowledge level concerning guidelines and switching/ titration methods is good (mean 3.9±0.7 and 4.0±0,8, respectively). Mean usage % of LAI was 28.4±22.6%, with only 16.7% of the sample using LAIs ?50% in their practice. Multiple linear regression analysis (stepwise selection) indicates that the % of LAIs use in real life clinical practice is statistically significant related to the physicians' practice since psychiatrists with only private practices report lower use of LAIs (p=0.001) and psychiatrists practicing in Thessaloniki report a higher use of LAIs (p=0.03). Conclusion: Despite the rather good knowledge and positive perception towards the clinical benefits of LAIs that the psychiatrists in Greece have, it seems that the use of LAIs is still low in Greece. Problems that clinicians face act as a barrier for increased usage in clinical practice and should be adequately addressed in the near future.

No. 30

Effects of Adjunctive Raloxifene on Symptom Severity in Women With Schizophrenia: A Meta-Analysis

Poster Presenter: Rachel Steere, D.O.
Co-Authors: Vedrana Hodzic, M.D., Andrea Hiyam Naaum, M.D.

SUMMARY:
Context: Growing evidence suggests that estrogen reduces the severity of positive and negative symptoms of schizophrenia. There is an increasing shift to investigating selective estrogen receptor modulators (Raloxifene) as they provide the protective effects of estrogen without the adverse effects on reproductive organs. Objective: To assess the effects of adjunctive raloxifene on symptom severity as measured by the PANSS when compared to antipsychotics alone in the treatment of adult women with schizophrenia or schizoaffective disorder. Data Sources: Electronic databases (PubMed, PsychINFO) were searched for randomized control trials published in English from January 1990 to October 2016. Search terms included: selective estrogen receptor modulator, raloxifene, schizophrenia, schizoaffective disorder, raloxifene hydrochloride. Study Selection: Eligibility criteria were RCTs of adjunctive raloxifene in the treatment of women with schizophrenia or schizoaffective disorder stabilized on antipsychotic medications. Studies were restricted to adults and had to include PANSS scores at intake and completion of treatment. Thirty-seven articles were found and 7 full text articles were assessed for eligibility, resulting in 3 studies for quantitative meta-analysis. Data Extraction: Two authors independently extracted data. Effect sizes were represented by standardized mean differences (SMD). Results: A total of 149 participants across 3 studies were included in the analysis, with 133 participants completing the studies. Compared to antipsychotics alone, adjunctive raloxifene showed improvement in the total PANSS score (SMD 1.194, CI 0.844, 1.545, p=0.000), positive PANSS score (SMD 1.222, CI 0.869, 1.574, p= 0.000), negative PANSS score (SMD 0.992, CI 0.651, 1.334, p= 0.000), and general psychopathology PANSS score (SMD 1.137, CI 0.789, 1.485, p= 0.000). Conclusions: This meta-analysis demonstrates that total and all PANSS sub-scores showed a significant response to treatment with adjunctive raloxifene when compared to antipsychotics alone in women with schizophrenia or schizoaffective disorder. These findings are promising as negative symptoms pose a significant treatment challenge.

No. 31

A Review of the Effects of Adjunctive 5-HT3 Antagonists on Symptom Severity in Adults With Schizophrenia

Poster Presenter: Andrea Hiyam Naaum, M.D.
Co-Authors: Rachel Steere, D.O., Vedrana Hodzic, M.D.

SUMMARY:

Schizophrenia is a complex neuropsychiatric disorder that can be profoundly debilitating, ranking in the top 10 causes of long-term disability worldwide and affecting up to 0.7% of the population during their lifetime. Symptomology is classified in 3 main clusters: positive symptoms, negative symptoms and cognitive deficits. The heterogeneity of symptoms signifies that there may be a need to identify differing etiologies for different disease with the syndrome. There are numerous neurotransmitter systems implicated in schizophrenia (dopaminergic, serotonergic, glutamatergic), which adds to the difficulty in effectively treating the disorder. The primary treatment for schizophrenia is antipsychotic medications, predominantly targeting the dopaminergic system. Antipsychotics primarily target positive symptoms, and have reduced efficacy on cognitive and negative symptoms. This has led to exploration of potential adjunctive treatments to extend the current therapeutic benefits of antipsychotic drugs. The finding that drugs with serotonergic antagonist properties (such as clozapine, quetiapine and olanzapine) are efficacious in treating schizophrenia, as well as the emerging role of for the serotonergic system in the pathogenesis of schizophrenia, have led to the investigation of 5-HT3 antagonists as treatments. Some studies have suggested that these antagonists may reduce negative symptoms and improve cognition in patients with schizophrenia. This literature review summarizes the findings to-date on the effects adjunctive treatment with 5-HT3 antagonists has on symptom severity and cognition when compared to antipsychotics in the treatment of schizophrenia. These findings may inform future prescribing practices for patients with schizophrenia.

ADHD Is Associated With Migraine: A Systematic Review and Meta-Analysis

Poster Presenter: Haitham Salem, M.D., Ph.D.

SUMMARY:

Background: An association between primary headaches and attention deficit hyperactivity disorder (ADHD) has long been suggested. Moreover, headache is regarded as a common side effect of stimulants, the most effective treatment for ADHD. So far, no systematic review has evaluated the potential association between ADHD and headache. Method: We performed a systematic review of the literature and a meta-analysis of all reported studies on ADHD and primary headaches. Results: Our analysis showed a positive association between ADHD and migraine (OR: 1.322, 95% CI: 1.018-1717, p-value: 0.036), but not to Tension Type Headache. Conclusion: There is a significant association between migraine and ADHD. The mechanisms underlying this association remain to be elucidated, warranting further studies. Keywords: ADHD, Headache, Migraine, TTH, Meta-analysis, Stimulants

Psychosis in a Patient With Retinitis Pigmentosa: Beware of D4 Receptor Blockade!

Poster Presenter: Haitham Salem, M.D., Ph.D.

SUMMARY:

Background: Retinitis Pigmentosa is a rare inherited degenerative eye disease affecting the retinal pigment epithelium (RPE), in which mutation of rhodopsin leads to severe visual impairment, and legal blindness by age 40. While Dopamine 2 (D2) receptor blockade remains the sine qua non of antipsychotic activity, the D2 family also includes the D3 and D4 receptors. Most atypical antipsychotics have high affinity for the D4 receptor. The D4 receptors are abundant within the rods of the retina and dopamine release is the primary feedback mechanism preventing retinal degeneration by the unopposed action of melatonin. With these issues in mind, the current case discusses the selection of an antipsychotic medication in the context of retinitis pigmentosa. Case Report: A 50-year-old female with Schizophrenia and Retinitis Pigmentosa was admitted to an inpatient unit at a free standing academic psychiatric hospital in Houston, TX for an acute psychotic exacerbation with agitation and persecutory delusions. She initially refused to take any antipsychotic medication due to her belief that the medication would further exacerbate her legally blind condition. Since she remained very psychotic, a petition for forced medication administration was filed and subsequently approved by the mental health court. Course and treatment rationale: Choice

of a specific antipsychotic medication was complicated by the patient's Retinitis Pigmentosa as well as her history of non-compliance to medication on an outpatient basis. Quetiapine and Abilify have a relatively low affinity for the D4 receptor, but no IM and/or depot formulations were available at the inpatient facility. Haloperidol was subsequently selected based on its similar D4 affinity to the remaining atypical antipsychotic medication, and also since it was available in an IM and depot formulation. Pt. initially was administered IM Haldol since she refused oral Haldol, but she eventually was compliant to oral Haldol with eventual reduction in daily dose to 5mg/d with eventual treatment response and good tolerability including no change in visual acuity. Conclusion and learning points: The treatment of psychosis in patients with Retinitis Pigmentosa is not only challenging, but requires consideration of the potential D4 receptor effects associated with an antipsychotic medication. Otherwise, further retinal damage may occur. Since there is little data available concerning this rare but important issue, this case report provides some guidelines for psychosis management in such patients. Keywords: Retinitis pigmentosa, Psychosis, Antipsychotics, Dopamine receptors, Melatonin

No. 34

Methylphenidate-Induced Obsessive Thoughts in a Patient With ADHD

Poster Presenter: Bharath Kumar Reddy Nandimandalam, M.D.
Co-Author: Balkozar Seif Eldin Adam, M.D.

SUMMARY:

Mr.X is a 10 yr old WM, diagnosed with ADHD at age 6yrs, presented to the hospital with aggressive behaviors including hitting, biting his mom and grand mom, running away from home. He was prescribed Concerta 18mg qam for ADHD. He was also tried on Adderall, Focalin, Vyvanse, Tenex, Strattera that were ineffective. He was tried on Concerta 36mg qam when he was 7yrs old and it helped some but was discontinued as it caused stomach upset. Over the years, his symptoms kept on worsening, and he continued to have poor grades in the school. In the hospital, patient continued to be fidgety, hyperactive, impulsive, would frequently run about or leave his place in situations where he was expected to be seated and would frequently interrupt others during their conversation, trying to bite and hit other peers, poor focus, easily distractible, very talkative. Concerta was increased to 27 mg qam which he tolerated, but still continued to be very hyperactive, impulsive, intrusive. He was then started on Ritalin 5 mg tid to treat his ADHD symptoms. A day later, patient had developed obsessive with doubts, asks the same doubt/questions to different staff members multiple times through out the day though he was answered. Ritalin and concerta were discontinued and his obsessions have resolved completely in 4-5 days. Methylphenidate have been used extensively for the management of ADHD. Evidence suggests that stimulants are more effective than placebo. The most common side effects associated with methylphenidate are headache, loss of appetite, weight loss, insomnia, irritability, agitation. Obsessive symptoms as a side effect of methylphenidate have rarely been reported and there are only few case reports describing these in children and adolescents. In this case presentation, we would like to discuss a patient with ADHD and methylphenidate induced obsessive symptoms and review available literature on methylphenidate induced Obsessive Compulsive symptoms.

No. 35

Autism Spectrum Disorder and Fetishism: Case Report and Review of Literature

Poster Presenter: Bharath Kumar Reddy Nandimandalam, M.D.
Co-Authors: Katherine Marie Edwards, M.D., Chad Robert Elder, D.O., Garima Singh, M.D.

SUMMARY:

Mr. X is a 17-year-old Caucasian male with a past history of anxiety disorder, learning disorder, and physical and emotional abuse who presented to the Autism Clinic given concern for behavioral and emotional rigidity, impaired social and communication skills, restrictive interests, sensitivity to fabric and sounds, and significant associated anxiety. His parents reported repetitive behaviors and the patient was observed to exhibit underproductive speech with abnormal prosody during mental status examination. After his initial evaluation, a trial of Zoloft 25 mg was initiated to

treat his anxiety, with additional recommendation to continue outpatient psychotherapy. During subsequent follow up visits, his parents raised additional concern regarding behaviors of a more sexual nature. Since the age of 13, the patient had been interested in feminine clothes and products, and had been found to hide his mother's underwear in his room and masturbate into them multiple times. The patient had also dressed himself as a female, having noted that this felt "good and natural", though reporting that it was "wrong" after having been "caught" by his parents. The patient had not been bothered by these thoughts, though ultimately did not want to have them, and denied wanting to be a female. Overall, his thoughts appeared ruminative in nature and were associated with some impulsivity. Given consideration of his overall presentation, fetishistic disorder was considered as a possible diagnosis. Inappropriate sexual behaviors in individuals with autism spectrum disorder (ASD) could result in significant distress for themselves and their families, and could disrupt their social development overall. There is limited research available that discusses fetishism in individuals with ASD, and further studies would be important, especially given that these patients already struggle with identifying social norms and engaging in social interactions. Having a comorbid paraphilias that overlaps with the symptoms of ASD makes treatment and management challenging. In this case presentation, we will discuss a patient with features of both ASD and fetishistic disorder and review available literature regarding the treatment and management of patients with these comorbidities.

No. 36

Contributing Factors for the Development of Antisocial Personality Traits: A Case Report

Poster Presenter: Ayesha Shaheryar, M.B.B.S.
Co-Authors: Naveed Butt, Asghar Hossain, M.D.

SUMMARY:

Introduction: Personality development is the continuous pattern of thoughts, feelings and behaviors that distinguish one individual from another. Per Freud, the adult personality emerges as a composite of early childhood experiences, based on how these experiences are consciously and unconsciously processed within human developmental stages, and how these experiences shape the personality. In this abstract, we focus on different contributing factors on the development of antisocial personality traits. Case report: We presented a case of 11-year-old Serbian male, with no prior psychiatric hospitalizations, who presented to emergency department secondary to encouraging an online acquaintance on snapchat to commit homicidal acts and mass shootings. The patient showed deep interest in playing online criminal/violent video games and events of the Columbine shooting. The patient was raised by his mother alone. There is a history of bullying. Patient is in gifted/talented classes. Discussion: Personality disorders affect 10-15% of US population and amongst those the prevalence of antisocial personality disorder is around 0.7-4.1%. Individuals with antisocial personality trait display a persistent pattern of disregard for and violation of the rights of others and the rules of society. There are many factors which can contribute to the development of antisocial personality trait. There are hereditary factors which can play a part but social and family environment are the major influence. It has been studied that child abuse, divorce, single parent, unstable family dynamics and alcoholism in one of the parents can lead to antisocial behavior in children. Similarly, children who are adopted or living in foster care are more prone to develop antisocial personality. Home environment without any discipline and supervision can be a major contributory factor. Impact of playing violent video games is another factor which needs a wide variety of research. In the past two decades, several correlational studies involving adolescents and young adults have found a small but significant relation between playing violent video games and aggression. It has been studied that 97% of adolescents aged 12 to 17 years play computer or portable video games but the alarming fact is almost half of the adolescent population plays violent video games. Children especially boys who are involved in watching crime movies or playing violent video games will find some tough warriors or heroes from games who frequently use aggression to solve problems, rarely being punished and shows no remorse for their aggressive behaviors. In developing their identity, adolescent boys may take ideals out of

these characters and use these ideals to guide their own behavior. Conclusion: There is a need of extensive research to establish the contributory factors in the development of antisocial personality traits especially the role of social media, video games and crime movies.

No. 37

Longitudinal Change in Health Status After the Sewol Ferry Accident Among Bereaved Parents

Poster Presenter: Sangeun Yang

SUMMARY:

Objective : The present study had examined the psychiatric symptoms and physical health consequences for the bereaved parents of the high school students who died in the 2014 Sewol ferry accident. Methods : Forty bereaved parents participated in the study. The authors administered self-report questionnaires about the parents' health behaviors and psychiatric symptoms. The authors also conducted laboratory tests to assess the parents' physical health at 18 and 30 months after the accident. Univariate descriptive statistics were performed to report the prevalence and severity of psychiatric symptoms and health-related behaviors. Paired t-test and mcnemar test were performed to compare the 18-and 30-month findings. Correlation analysis between psychiatric symptoms and laboratory findings were performed to find a relationship between the two variables. Results : At 30 months after the accident, most of the bereaved parents still appeared to suffer from complicated grief (97.5%), post traumatic stress disorder (80%), insomnia (77.5%) and severe depression (62.5%) based on the scores on the Inventory of Complicated Grief (ICG), the PTSD Check List-5 (PCL-5) ,the Insomnia Severity Index (ISI) and the Patient Health Questionnaire-9 (PHQ-9). One quarter, 25%, of the bereaved parents reported high-risk drinking, and 47.5% reported increased drinking amount and frequency after the accident. In objective laboratory results, 55% of the bereaved parents were obese as defined by body mass index ≥25. The parents' mean low-density lipoprotein shows a significant increase over time (118.5 mg/ dL at 18 months. vs. 132.5 mg/dL at 30 months. paired t-test t=-4.061, p?0.001). Total cholesterol and low-density lipoprotein at 30 months after the accident were in clinically borderline high range. In correlation analysis, triglyceride was positively correlated with ISI. Conclusion : The loss of children in the Sewol ferry accident, a disaster caused by human error, continued to have considerable impact on the victims' parents' mental and physical health 18 and 30 months after the accident. A longitudinal study following the parents' physical health would be necessary to investigate the long-term effects of this traumatic experience on physical health.

No. 38

Do Parents and Children Report the Same Psychiatric Symptoms? Comparison of *DSM-5* Level 1 Self and Parent-Reported Cross Cutting Symptom Measures

Poster Presenter: Mark Peterson

SUMMARY:

Background DSM-5 Level 1 cross-cutting surveys were introduced in 2013 under "emerging measures" in Section III of DSM-5. They were designed to monitor responses to treatment over time [1]. For the child and adolescent population, special surveys were designed to assess symptoms based on the guardian's perception in addition to that of the patient's self-report. Previous research has shown disagreement between parent-child surveys [2,3]. This study was conducted to assess interrater agreement between parent and child using this measure. Methods Patients, aged 11-17, and their guardians were given DSM-5 Level 1 cross-cutting surveys before their appointments at a university child and adolescent psychiatry clinic. Psychiatric diagnoses were obtained through chart review. Each of the 25 questions was tested for interrater agreement. Results 70 pairs completed the survey. Interrater agreement showed wide variation with kappa values ranging from -.04 to .83. Two thirds of the questions had kappa values less than .4 indicating low agreement levels. Six questions showed good agreement with kappa levels at .4- . 75. Only three questions showed excellent agreement with kappa values above .75. Symptom categories with the lowest agreement were inattention, anger, irritability, and psychosis. The most common diagnoses were ADHD (n=53), MDD (n=25), and GAD (n=24). No subjects carried a diagnosis of any psychotic disorder. Two questions

addressed suicidality. The question asking if suicide has been attempted had very high agreement. The question asking if there have been thoughts of suicide (child survey) or talk of suicide (parent survey) had very low agreement. It was answered positively more often by the guardian (n=5) than by the child (n=2). The highest degree of agreement was in questions addressing substance abuse. Discussion This study found frequent disagreement between parent and child. This emphasizes the importance of gathering information about each domain from both sources when evaluating adolescents. Using the Level-1 screen allows clinicians to gather this range of information in an efficient manner.

Validation of the Mexican Versión of the Yale Food Addiction Scale for Children: The Identification of Psychopathology in a Non-Clinical Sample

Poster Presenter: Martha Paola Corral Frias
Co-Authors: Alfredo Bernardo Cuellar-Barboza, Antonio J. Lopez

SUMMARY:
Background: Food addiction is positively associated with obesity and mental pathologies; therefore it is considered a specific risk mechanism for obesity. Understanding obesity-related phenomena such as food addiction is therefore critical in our population, especially in the child population that is exposed for a longer time to the harmful effects of these entities. At the same time, we propose to evaluate the prevalence of mental health problems in children with addiction to food; to determine its clinical impact more clearly and thus establish a clinical phenotype Methods: To the pediatric patients that are positive on the YFAS-C scale applied by the study Validation of the Yale Scale for Food Addiction for Children YFAS-C in Mexican children and adolescents were contacted to be interviewed. The study consists of a single visit where consent and informed consent will be made. The structured interview MINI International Neuropsychiatric Interview (MINI KID) was conducted in its Spanish version (Sheehan et al., 2000). Results: Study in phase of recruitment of patients. Five of thirty-eight patients were recruited, of whom 80 percent were women, 100 percent were in high school, with a mean age of 15.6, 40 percent resulted with alteration in weight (1 with overweight and 1 with obesity). MINI KIDS was applied, 60 percent of the patients recruited were positive for a mental pathology. Conclusion: In this study we report, there is a high prevalence of mental pathology and food addiction.

No. 40

Behavioral Assistance Response Team Effectively Provides De-Escalation and Aggression Management at a Large Tertiary Children's Hospital

Poster Presenter: Daniel Nicoli, D.O.
Co-Authors: Anne Penner, Beau Carubia

SUMMARY:
Background: In pediatric inpatient settings, staff often feel uncomfortable managing youth with complex psychiatric comorbidities who may be at increased risk of agitation, potentially requiring de-escalation or seclusion and restraint (S&R). S&R is a rare occurrence on medical floors, and staff often have insufficient experience and training (Zicko et al., 2017). To address this, solutions have been proposed including additional nursing education, increased nursing exposure to psychiatric patients, implementation of psychiatric consultation-liaison services, and more recently, rapid response teams that specialize in behavioral emergencies (Pestka et al., 2012). There is very limited guidance in the literature regarding the effectiveness of these teams and no evidence of best practices for managing agitated children in the medical setting. Our institution, a tertiary children's hospital with over 400 beds, instituted a Behavioral Assistance Response Team (BART) in 2010. Methods: The BART consists of a multidisciplinary team that is designed to intervene when there is the potential of immediate harm due to a patient's behavior and additional resources are immediately needed. When called, the team, directed by a lead mental health counselor, works collaboratively to assist in de-escalation and determine the patient's immediate needs. Afterwards, the team debriefs with staff and discusses further recommendations such as additional supervision and formal psychiatric consultation. The bedside nurse records data including the reason for code, interventions, and patient response within the EMR. Results: From 2015-2016, there were a total of 68 code BARTs. The

most common reason was an aggressive or agitated patient (57%), followed by danger to self (15%), assaultive (9%), other (9%), and no reason listed (3%). In total, only 14 patients required restraints. Restraint was required in only 33% of the assaultive, 21% of the aggressive, 20% of the out of control, and 10% of the danger to self patients. Of those who were restrained, 29% became further agitated, 43% had no change in behavior, and 29% became calm and cooperative. Conclusion: This innovative service integrates pediatric medical and mental health providers and staff to better serve agitated patients. This model describes a frequently used and feasible service, that could be replicated more broadly. Our data demonstrate that even assaultive patients are often managed with less restrictive interventions. This may be due to the specific mental health experience and verbal de-escalation training possessed by the team members. And, in instances when more restrictive means are required, trained mental health staff are present to facilitate a safe process. In addition, there are potential benefits that could be further studied such as decreased instances of S&R and injuries, which make this model a promising way for hospitals to cut costs while also improving patient outcomes.

No. 41

A Study on the Relationship Between Inpatient Adolescents' Ratings of Object Relations and Psychopathology

Poster Presenter: Michael Esang, MB.Ch.B., M.P.H.
Co-Author: Gregory Haggerty, Ph.D.

SUMMARY:

The current study looks to investigate the relationship between inpatient adolescents' ratings of object relations and psychopathology. The study included 66 adolescents who were hospitalized on an acute inpatient unit. The patients' group and individual psychotherapists completed ratings on the patients' object relations using the Social Cognition and Object Relations Scale-Global (SCORS-G, Stein et al. 2011) and also completed ratings of prototypes of 5 common disorders (Guamaccia, Bradley, Westen, unpublished manuscript) seen with adolescent inpatients (ADHD, Conduct Disorder, Major Depressive Disorder, Generalized Anxiety Disorder, and Post-Traumatic Stress Disorder). The ratings were completed at the patients' discharge from the unit and raters were blind to each others' rating. The findings show that the SCORS-G ratings show negative correlations with the prototype ratings of the 5 disorders. The only exception was a slight positive correlation with all the items of the SCORS-G and the Major Depressive Disorder prototype. Both clinician-rated measures showed good inter-rater reliability. Clinical implications are discussed.

No. 42

Is This Premorbid Schizophrenia or Major Depression: A Case Report?

Poster Presenter: Ayesha Shaheryar, M.B.B.S.
Co-Authors: Naveed Butt, Asghar Hossain, M.D.

SUMMARY:

Schizophrenia, whilst markedly interfering with individuals functioning is characterized by positive and negative symptoms, mood symptoms and as well as neurocognitive deficits. Identifying Schizophrenia in its early stage is a crucial step as some of the symptoms commonly observed in the initial stages have a close overlap to symptoms of Major Depression Disorder. We presented a case of 16-year-old male without any history of previous hospitalizations and psychiatric illness, presented to the hospital due to increased agitation and aggression towards his mother. Triggers included his worsening social withdrawal and isolation, and deterioration of ability to care for his ADLs such as showering and grooming. The patient exhibited negative symptoms, such as blunted affect, poverty of speech and thought, apathy, anhedonia and lack of social desire or interest. He had become progressively socially withdrawn over the last few years. His diagnosis was difficult to establish as the symptoms may be due to major depression or premorbid state of schizophrenia. Depression is one of the most prevalent among the psychiatric illnesses as 7.6% of American aged 12 and older suffered from major depression (during 2009 to 2012) but it has a much better prognosis with appropriate treatment with 70-80% of patients achieve a significant reduction in the symptoms. Some of the symptoms of major depression like anhedonia, depressed mood, social isolation, lack of sleep and lack of motivation are hard to distinguish from the prodromal phase of schizophrenia.

Evidence from multiple researches suggested that the prodromal period which can last from weeks to several years. It is suggested that the earliest symptoms that individual experiences are the negative symptoms like anhedonia, depression, anxiety and social isolation with some impairment in daily functioning. The basic symptoms which are considered as significant include impaired bodily sensations; subjective experiences of thought, language, perception and motor disturbances; impaired tolerance to stress and disorders of emotion, energy, thought and memory. These early symptoms can affect social and cognitive development. Later, one can develop positive symptoms of brief or moderate intensity. During this prodromal phase, there is a high risk of comorbid disorders. In order to diagnose schizophrenia in the early stage, different assessment scales can be used. One such scale is known as CAARMS scale (Comprehensive Assessment if At- Risk Mental States), which is based on the intensity, frequency and duration of emerging positive symptoms, as well as decline in functioning. It is important to diagnose the patient in this early stage as early intervention can lead to improvement in prognosis of patients with schizophrenia.

No. 43

The Effects of Prenatal Exposure to Marijuana on Early Childhood Development: A Systematic Review

Poster Presenter: Dhurga Krishnamoorthy, M.B.B.S.

SUMMARY:

Aim: To assess the effect of prenatal marijuana exposure (PME) on the newborn, infant and early childhood development. Methods: A systematic review was conducted in the electronic database from 1996 to 2017 for the effects of PME and their fetal and early childhood outcomes. Results: Seven percent of pregnant women self-reported using marijuana in the last year, while 16% of them reported near-daily use. Marijuana use has been reported to: a) interfere with normal placentation leading to miscarriage, preeclampsia and preterm labor through imbalance in Cannabinoid receptor type 1 (CBR1) stimulation; b) cause reduction of fetal growth and head circumference due to increased pulsatility and resistance of uterine artery; c) be associated with impaired memory function, decreased verbal scores, increased aggression and hyperactivity, impaired abstract and visual reasoning; and d) cause alteration in sleep patterns. Finally, there is no consensus regarding the effects of marijuana through breastfeeding exposure and no postpartum withdrawal effects in the newborn were reported. Research on the effects of PME on offspring has been limited by several confounding factors including self-reporting bias, concomitant use of other illicit drugs and psychosocial factors. Conclusion: Overall, PME may lead to negative consequences on the developing offspring. Public health messages to health care providers and pregnant women regarding the harmfulness of PME should become a high priority. Further research is needed to reinforce the existing data and examine additional potential negative effects on the developing child. Keywords: Marijuana; cannabis; pregnancy; outcomes; prenatal; fetal; perinatal; neonatal; early childhood.

No. 44

Gender Fluidity: An Identity Issue or a Relationship Issue?

Poster Presenter: Dhurga Krishnamoorthy, M.B.B.S.

SUMMARY:

This is a case study about a 17 years old adolescent female by birth with h/o bipolar 1 disorder MRE mixed with psychotic features, parent child relationship conflict and sexual trauma, who switches between male and female. Initially she was thought to have been gender fluid but longitudinal follow up explains that her gender identity shifts in relation to the people she hangs up with. It explains how poor object relations and interpersonal relationship with others influenced her gender fluidity.

No. 45

Rizatriptan-Induced Mania-Like Symptom in an Eight-Year-Old Girl

Poster Presenter: Hitekshya Nepal, M.D.

SUMMARY:

Bipolar disorder in children is difficult to diagnose because of considerable overlap of symptoms with co-morbid disorders. Triptans are FDA approved migraine abortive medications. We present an 8

year old girl referred by her pediatrician for rapidly changing behaviors following 3 days use of Rizatriptan for migraine. According to the informants, she started having headaches for two weeks in the evening, for 4-5 hours, exaggerated by sound and light. She was initially treated with analgesics with minimal relief. Patient was started on Rizatriptan 10mg daily for migraine. Three days later, she started having decreased sleep (total duration 3-4 hours with early awakening). Parents began to notice she started being hyperactive and irritable through the day. Her sleep decreased further to about 2-3 hrs total. Patient was found to have increased energy, performing goal directed tasks like cleaning her room and making colorful crafts. She was playing with her dog imagining it to be a tiger and she being a hunter. The behaviors then started getting aggressive, she threw utensils from the kitchen stating that she would get better ones. She was hyper talkative and her speech was rapid. She was talking with alot of gestures, making faces and moving her hands in air. She started getting obsessed with applying makeup most of the time. She was found texting her male peers and writing letters to them expressing her sexual fantasies. There was no history suggestive of any medical condition. There were no other psychiatric symptoms. History was negative for abuse and any substance exposure. Family history was significant for anxiety in mother and bipolar disorder on treatment with Lithium in both paternal and maternal grandmothers. Vitals including physical examination was within normal limits. Mental status examination showed a child per stated age constantly moving in the room with significant fidgety. Speech was pressured with increased rate and rhythm, loud. Mood was irritable and affect was animated. Grandiose delusions were present. No auditory or visual hallucination seen. The complete blood count, chemistries and thyroid function was within range. CT scan of head and an electroencephalogram revealed no abnormalities. The patient was started on Valproic acid 250 mg twice daily with Risperidone 1 mg. She developed some dystonia, the Risperidone was stopped, and was treated with diphenhydramine. Patient then showed some improvement in her symptoms. The irritable mood with pressured speech and impulsive behaviors continued for which she was started on Aripiprazole. Patient had complete resolution of symptoms on this combination over 6 weeks. With this case, we highlight that mania can be induced in children with triptans which are commonly used in treatment of migraine. Clinicians should arrange for close follow up for any patients taking triptans and should be vigilant to recognize any change in behavior induced by triptans to provide prompt treatment.

No. 46

Copycat Suicide Attempt Following Netflix Show "13 Reasons Why": A Case Report and Literature Review

Poster Presenter: Muhammad Zeshan, M.D.
Co-Authors: Pankaj Manocha, M.D., Muhammad Hassan Majeed, M.D., Sadiq Naveed, M.D., Ahmed Waqas

SUMMARY:
Objectives: The impact of media industry on the acts of suicide has been an area of interest for clinicians. Our aim is to investigate the copycat effect of the portrayal of suicide attempt in the media industry. We also explored the preventive effect of these shows on such imitative acts. We present the case history of an adolescent with the history of bullying who self-identified herself like a character "Hannah" in Netflix show "13 Reasons Why". She engaged in self-harm to ease her emotional pain by mimicking herself as a Hannah in the show. The patient reported that as the season progressed, "Hannah's" parent went through suffering and pain after her death. The patient did not want her family to face pain and suffering which kept her from self-harm. Methods: We searched PubMed database for relevant articles, using terms "copycat suicide attempt" or "imitation suicide attempt", and "media" in the last 5 years. Results: Our literature review shows that both fictional and nonfictional suicide stories have a real effect on the minds of adolescents. This "suicide contagion" is frequently observed in high schools and college campuses and is a part of broader effect often known as behavioral contagion or media contagion. The impressionable nature of adolescents puts them at a higher risk of suicide, by using the similar methods of suicide shown in media, when they watch a portrayal of suicide in a fictional show. It is also evident that

news media has a stronger influence on the minds when compared to fictional formats. The burden of the portrayal of suicide in the fictional and non-fictional suicide stories depends on the news directors and journalists. At times, they glamorize the suicide rather presenting it in a way that encourages help-seeking behavior and prevents imitation. Conclusions: Mental health experts have a role in educating the media to deglamorizing the act of suicide or reporting a suicide in order to dampen the media contagion effect which can reduce the imitative behavior.

No. 47

Electroconvulsive Therapy (ECT) in Children With Autism: A Systematic Review of the ECT Practice

Poster Presenter: Raul Johan Poulsen, M.D.
Lead Author: Samantha B. Saltz, M.D.
Co-Authors: Stuart Sacks, Julie Furst, M.D., Heather Barkin, Judith Regan

SUMMARY:

Objective: Electroconvulsive therapy (ECT) has been used for refractory psychiatric conditions in the U.S. since 1938. Despite this, few practitioners are comfortable recommending ECT for minors. Ghazzudin et al. reported that, 75% of surveyed child and adolescents psychiatrists felt uncomfortable providing a 2nd opinion for ECT in children. Pediatric ECT is an emerging field that benefits from scientific query. We performed a systematic review to evaluate available information on ECT in children with autism. Methods: With a research librarian, three databases were included (Cochrane, Embase, and Pubmed) in our systematic review. Cases in languages other than English, as well as those with persons over the age of 18 were excluded from analysis. 22 cases met inclusion criteria. Results: Children with autism who received ECT were between the ages of 8 and 17 with a mean of 14.86 years. 73% of included cases were male. Most children had a comorbid diagnosis of Catatonia (82%), Mood Disorder with Psychosis (14%), Bipolar Disorder (9%), Major Depressive Disorder (5%), Schizophrenia (5%) or Tourette's (5%). Children had been treated with several psychotropic and neurotropic medications with minimal effect including: 1st and 2nd generation antipsychotics (8/19=42.1%, 12/19=63.2%, respectively), SSRIs (13/21=61.9%), Monoamine Oxidase Inhibitors (1/21=4.8%), Tricyclic Antidepressants (3/21=14.3%), benzodiazepines (12/20=60%), stimulants (5/21=23.8%) and mood stabilizer/anticonvulsants (12/20=60%) (Total > 100% secondary to polypharmacy). Symptoms were not well controlled; therefore patients were offered ECT. Both Bilateral (19 reported cases) and Unilateral (3 reported cases) ECT were used. Children received 10 to 156 ECT treatments. Induction agents included propofol (9% total cases), methohexital (55% total cases), 36% unreported. Neuromuscular blockers (NMB) included succinylcholine (59% total cases), 41% unreported. Anticholinergic agents included glycopyrrolate (32% total cases), 68% unreported. ECT-induced seizures lasted from 26-206 seconds as measured by EEG. ECT was overall well tolerated with rare side effects including: fatigue, hunger, and postemergent agitation. All children benefited from ECT. 11 cases reported data on school attendance, and 11/11 attended school after ECT. Conclusion: Many children with chronic mental illness do not improve with oral medications and respond to ECT. We believe that ECT may be an underutilized treatment in minors. Education must be provided to practitioners and to families who are affected.

No. 48

Psychiatric Re-Admissions for Inpatient Stabilization, Evaluation on Youth: A Review of the Literature

Poster Presenter: Raul Johan Poulsen, M.D.
Co-Authors: Ariel Smith, B.S.N., R.N., Cory Patrick, Sarah Georges Denaud, M.D., Robert Ryan Leahy, M.D., M.S., Aarti Uberoi Jerath, M.D., M.A., Gerson J. Knijnik, M.D., Viral M. Patel, Angela Chang, Barbara J. Coffey, M.D.

SUMMARY:

Abstract: Hospital readmissions have been a focal point in health research due to concerns over increasing admission rates for youths, effectiveness of inpatient care, variable post-discharge outcomes, availability of aftercare treatment, and concerns of overall hospitalization burden. The goal throughout a patient's hospital stay remains to provide continual risk assessment, psychiatric crisis care, and facilitate safety and stabilization prior to discharge into the community. Despite efforts to prevent readmission

to inpatient facilities, adolescent readmission rates are as high as 19-28% within the first six months. Utilizing the American Hospital Association's Framework for Classification of Readmission, this literature review aims to determine factors influencing readmission rates of youth treated in inpatient hospital settings and investigate interventions used to reduce psychiatric readmissions. With the assistance of a research librarian, multiple databases were included (Cochrane, Embase, and Pubmed) in our review. Search terms of "Readmission", "Re-hospitalization", "Psychiatric", "Psychiatry", are used in the review. Studies with more than half of the population over the age of 18 and studies addressing recidivism, juvenile detention centers or correctional facility admissions were excluded from the analysis. Articles will be reviewed using established inclusion and exclusion criteria following title, abstract and full-text review. The results and conclusions from the review will be utilized to examine factors affecting readmission rates and address challenges facing acute psychiatric care and aftercare interventions for youth.

No. 49

Characteristics and Outcomes of Children That Suffered Sexual, Physical and Emotional Abuse: A Single-Center Retrospective Cohort Study

Poster Presenter: Reinhard Dolp, M.D., M.Sc.

SUMMARY:

Background: Abused children and youth have special mental health needs and characteristics that, are yet to be fully understood to improve care and prevent adverse outcomes. This single-center retrospective cohort study evaluates clinical characteristics and outcomes of abused patients below 18yrs, seen in an acute psychiatric clinic. Methods: This is a retrospective cohort study of patients assessed by the Child and Adolescent Urgent Consult Clinic from 2014 to 2016. This university clinic serves patients <18years who are deemed to be in crisis, need to be assessed within 48h, but do not require hospital admission. Clinic data base gathers information on demographics, previous hospital admissions, referral diagnosis, clinic assigned diagnosis, and outcome after assessment. First, we compared all patients that reported any type of abuse (sexual, physical, or emotional) with non-abused patients. Then, we stratified the abused patients into children that suffered only one type of abuse vs. children that suffered all three types. Lastly, we compared patients that experienced different kinds of abuse with each other. Statistical significance was determined via t-test and chi square with Fisher's exact test. Results: The analysis included 1465 patients - 451 that reported abuse (mean age=15, SD=2.0, 51% male) and 1014 non-abused patients (mean age=14, SD=2.6, 62% male). The Abused group had a higher prevalence of substance abuse (53% vs. 31%, $p<0.001$) and were bullied more often (46% vs. 41%, $p<0.05$), had significantly higher suicidal ideation (72% vs. 66%, $p<0.05$) which was the main reason for referral. The abused group had less behavioral problems (16% vs. 21%, $p<0.05$) and anger/aggression (11% vs. 18%, $p<0.05$). Abused patients were not only seen more often by a psychiatrist before being referred to us (14% vs 8%, $p<0.01$), but they also required more hospital admissions after assessment (8% vs. 4%, $p<0.01$). PTSD was a more common diagnosis in the abused group (7% vs 1%, $p<0.001$) but no other diagnostic differences were found. Children exposed to all three types of abuse had more self-harming compared to ones that suffered from only one type (34% vs. 16%, $p<0.01$). The abused group had more past psychiatric contact (23% vs. 10%, $p<0.05$) and a higher rate of PTSD (15% vs 5%, $p<0.05$). Surprisingly, when comparing children that suffered exclusively from emotional vs. physical vs. sexual abuse, no relevant difference could be found. Conclusion: Abused patients were more suicidal and had increased earlier contact with the mental health system. This finding further highlights the need for early recognition and intensified psychiatric care of abused children. Co-occurrence of different types of abuses seems more predictive of self-harming behaviours and mental health service needs than types of abuses itself.

No. 50

When Genetic and Medical Comorbidities Confound the Psychiatric Presentation

Poster Presenter: Sabrina Ali, M.D.

SUMMARY:

An integrative approach to medical care is becoming

common and yet specialities in medicine continue to operate with minimal interaction in the outpatient setting. In an adolescent patient with progressive neurological deficits and uncommon genetic variants, a collaborative approach is necessary to facilitate proper psychiatric diagnosis and treatment. A 15-year-old Filipino-American male, born in Illinois, domiciled with parents, enrolled to start the 10th grade in regular education was brought to the psychiatric emergency room by parents' due to patient's report of depressed mood with thoughts of wanting to "hang himself". Patient has a psychiatric history of unsuccessful treatment with Zoloft 50mg for depression three months prior and a medical history of progressive hemiparesis of right upper extremity and sensorineural hearing loss with +GLB2 mutation. He presented with greater than 3-week history of decreased appetite, increased sleep, low energy, poor concentration, suicidal ideation and anhedonia. On interview, he was oddly related, hypervigilant, at times appeared internally preoccupied and reported intermittent auditory hallucinations of "non-distressing" female voices. On the unit, he presented with speech latency, alogia, isolative behavior and concrete thinking. He has a positive family history of depression in father and suicide in father's cousin. Genetic testing was completed that showed mutations in GJB2, SV2A, and UTRN. Minimal understanding of genes SV2A and UTRN complicate his presentation due to limited mutation studies demonstrating possible correlations with the GABAergic system, as well as one case report of new onset schizophrenia. Neurological history revealed that at 7 years old, following a 3-day febrile illness with no clear etiology, patient developed acute right hand and elbow weakness. Initial MRI of cervical spine showed cord swelling from C5-C7, which was normal at 3-month follow-up. MRI of brain was also normal. EMG studies showed diffuse motor nerve damage with axonal loss. Patient initially demonstrated improved functioning of right side with physical therapy. One year ago, patient progressively developed atrophy of right upper extremity including face, leading to significant disability and low self-esteem. The etiology of the patient's neurological deficits is unlikely to directly contribute to the psychiatric presentation; however, his disability is a psychosocial stressor which had not been addressed until he became isolative and suicidal. This case illustrates the importance of an integrative approach. Throughout the course of his illness, each speciality approached his medical concerns in silos, preventing a comprehensive understanding of his declining medical presentation. His psychiatric presentation remains diagnostically uncertain due to a lack in collaborative care. Given the complexities of this case, knowledge and information exchange between specialists is necessary to provide adequate treatment.

No. 51

Understanding Parental Alienation

Poster Presenter: Kunal Maini, M.D.
Lead Author: Astik Joshi, M.D.
Co-Authors: Shawn E. McNeil, M.D., Lee Stevens, M.D., Maneek Kaler, M.D.

SUMMARY:

Parental Alienation is a highly under-recognized form of child abuse. It is especially important for the clinicians to recognize it in the field of Child and Adolescent psychiatry. Through conflict over an extended period of time, either the unfavored parent or the affected child come to the conclusion that they no longer wish to have a relationship with the other, as the emotional and physical results of having one outweighed the benefits.

No. 52

Recidivism Among Adolescents With Substance Use Disorder

Poster Presenter: Kunal Maini, M.D.
Co-Authors: Astik Joshi, M.D., Shawn E. McNeil, M.D., Maneek Kaler, M.D., Lee Stevens, M.D.

SUMMARY:

Our case review indicated that many young people who persistently abuse substances often experience an array of problems such as academic difficulties, health and mental related problems, poor peer relationships, and involvement with the juvenile justice system. Substance abuse is associated with both violent and income-generating crimes by youth. This increases fear among community residents and the demand for juvenile and criminal justice services, thus increasing the burden on these resources. Gangs, drug trafficking, prostitution, and growing

numbers of youth homicides are among the social and criminal justice problems often linked to adolescent substance abuse.

No. 53

Deutetrabenazine Versus Valbenazine: Which One Would You Choose for Tardive Dyskinesia?

Poster Presenter: Kunal Maini, M.D.
Co-Authors: Astik Joshi, M.D., Lee Stevens, M.D., Maneek Kaler, M.D.

SUMMARY:

Tardive dyskinesia is an uncontrolled, often irreversible, movement of the face, tongue, trunk and extremities that occur in patients having been treated with long term dopaminergic antagonist medications. In early 2017 the FDA approved Valbenazine, and most recently Deutetrabenazine, for the treatment of tardive dyskinesia. Upon comparing and contrasting the two medications, it was found that Valbenazine and Deutetrabenazine exerted their affects through similar mechanisms of action; reversibly inhibiting Vesicular Monoamine Transporter type 2 (VMAT 2), which reduces the secretion of monoamines, such as dopamine, serotonin, norepinephrine and histamine. Our literature review will demonstrate that both medications had promising results but with side-effects that may hinder the choice of selecting one or the other. It was discovered through our research that Valbenazine side effects included QT interval prolongation and drowsiness, in comparison to Deutetrabenazine, which had a variety of side effects ranging from sedation and fatigue to GI upset and hepatic impairment, as well as a black box warning for depression and suicidality in patients with Huntington's disease. Furthermore, it was found that Valbenazine was easier to administer, as it required a daily dose of 40mg/day, being increased only to 80mg/day a week later, whereas Deutetrabenzine had to be titrated to a recommended dose of 12mg-48mg with 6mg tablets. There are now only two available treatment options for tardive dyskinesia. More research needs to be done as there are no head-to-head trials of valbenazine vs. deutetrabenazine. The choice of the drug should be patient based, depending on individual tolerability including certain risks vs. benefits in that specific patient.

No. 54

Treatment Modalities for Self-Cutting Behavior: Case Report

Poster Presenter: Shahan Sibtain, M.D.
Co-Authors: Naveed Butt, Sheema Imran, M.D., Asghar Hossain, M.D.

SUMMARY:

Shahan Sibtain MD, Naveed Butt MD, Imran Mirza (M.B.B.S), Sheema Imran MD, Asghar Hossain MD

Self-Injury also called self-mutilation, self-harm or self-abuse is a group of behaviors which involved deliberately harming your own body surface area by cutting, burning, scratching, bruising or infecting oneself in the absence of suicidal intent. It can be a symptom of various psychiatric illnesses: Borderline personality disorder, Bipolar disorder, Major depressive disorder or Schizophrenia. It can also be due to inner conflicts, stressors, family problems, impulsivity or sense of hopelessness. We present case of 16 years old female who came to ER with superficially cutting behavior secondary to acute stressors and mild depressive symptoms requiring inpatient admission. She was treated with SSRI with counselling and therapy while she was inpatient. There is no single treatment modality to address the self-cutting behavior. If the behavior is secondary to Depression, Anxiety or Psychosis then addressing the psychiatric illness is the best option and then comes the treatment of self-cutting. The best treatment option is the combination of medication and psychotherapy which involved cognitive behavioral therapy, dialectical behavioral therapy, interpersonal therapy or stress reduction and management skills. Cognitive/behavioral therapy helps individuals understand their negative, unhealthy beliefs and replacing those beliefs with positive thoughts. Dialectal behavior therapy helped the individual in managing emotions, improve interpersonal relationships and help to cope with stress. There is a high role of group sessions and family therapy in the management of self-cutting behavior. Hospitalization either short term or long term may be needed depending upon the severity of illness. Medications may be needed but no specific medication is there to address the self-cutting behavior, medications can be given for the treatment of psychiatric illness like depression or

psychosis if the self-cutting is secondary to these disorders. The long-term prognosis is poor especially in adolescents as it is very difficult to treat and resulting in readmission.

No. 55

Management of Psychosis and Mood Symptoms in a Patient With Possible Polysystic Ovarian Syndrome

Poster Presenter: Shahan Sibtain, M.D.
Co-Authors: Naveed Butt, Sheema Imran, M.D., Asghar Hossain, M.D.

SUMMARY:

Naveed Butt M.D., Vasmeen Ratra, Shahan Sibtain M.D., Sheema Imran M.D., Asghar Hossain, M.D. We present a case of 44 years old female with established diagnosis of schizoaffective disorder who presented with an acute episode of psychosis presenting with persecutory delusions, decreased sleep, hyper-talkative secondary to noncompliance with her medications. On examination she had features like Hirsutism (with male-pattern hair growth), obesity, and menstrual disturbances etc suggesting hyperandrogenism possibly secondary to PCOS. She was tried on Paroxetine, Ziprasidone, Haldol, Risperidone, Depakote, and Lithium with limited response due to noncompliance with the medications. It appears that her physical sign and symptoms could be secondary to side effects of the medication she was tried on in the past. There has been reported association between PCOS and VPA, with contradictory results. There are various mood stabilizer like lithium, valproate, lamotrigine and various atypical antipsychotics available for the management of mood symptoms in bipolar disorder. Depakote form of valproic acid is approved for the acute phase of bipolar disorder. It is also commonly used for maintenance treatment. Valproate is more effective in rapid cycling and mixed episode bipolar disorder than lithium, however there is also increased noncompliance associated with secondary to the side effect profile of the medication. There is also increasing concern due to these side effect which ranges from gastrointestinal (GI) distress and sedation, to menstrual disturbances, polycystic ovaries and hyperandrogenism, making management a challenge for the psychiatrist. Through our case we will attempt to discuss the treatment modalities available to control the psychiatric symptoms while minimizing the side effect profile

No. 56

Evolution of Function and Sleep in a Sample of Schizophrenic Patients During One Year of Treatment With Long-Acting Injectable Paliperidone Palmitate

Poster Presenter: Adolfo Benito

SUMMARY:

Background: Poorer function in schizophrenia is related to poorer quality of sleep and to an increased prevalence of sleep disturbances and insomnia of all types in schizophrenic patients. Drugs such as long acting injectable paliperidone palmitate have been shown to be effective in improving both function and sleep. Objectives: To assess the evolution of function and sleep in a sample of patients diagnosed with schizophrenia during one year of treatment with paliperidone. Methods: Schizophrenic patients from three Mental Health units in the province of Toledo (Spain) were recruited. The inclusion criteria were an age over 18 years, a diagnosis of schizophrenia (based on the ICD-10 criteria), the start of treatment with long acting injectable paliperidone palmitate, and the non-utilization of any drugs such as hypnotics or sleep correcting agents. A series of demographic variables were recorded and the PSP (Personal and Social Performance) scale was used to assess function, while the COS (Sleep Oviedo Questionnaire) scale was used to evaluate subjective sleep quality and the severity of insomnia (categorical and dimensional variables of the scale). The scales were again applied 3, 6 and 12 months after the start of treatment. Results: N=97 patients (73 males and 24 females), with a mean age of 38 years. The predominant diagnosis was paranoid schizophrenia (62%). There were 7 dropouts during the year of follow-up. The results showed an improvement in PSP score during the 12 months, manifesting from the third month (ANOVA, $p<0.05$). Likewise, statistically significant differences (ANOVA, $p<0.05$) were observed with the COS scale for both severity of insomnia and subjective sleep quality; these results persisted over the year of follow-up and were manifest from the third month.

Conclusions: Oral paliperidone improved function and sleep in our sample of patients diagnosed with schizophrenia during one year of treatment, improving subjective sleep quality and reducing the severity of insomnia.

No. 57

Analysis of Internalized Stigma and Attitude to Medication in Schizophrenic Sample During One Year of Treatment

Poster Presenter: Adolfo Benito

SUMMARY:

Background: Non adherente is a mayor problem in the treatment of schizophrenia. Its high prevalence, potentially severe consequiences and associated costs make this phenomenon a priority issue. Most of the publishes reports confirm the significant contribution of attitudes towards treatment and its impact on adherence and clinical outcomes. Otherwise internalized stigma refers to the process by which individuals with mental illness apply negativa sterotypes to themselves, expect to be rejected by others, and feel alienated by society. Internalized stigma is related with quality of life and treatments adherence. Objective: To assess the evolution of internalized stigma and attitudes towards medication in a sample of patients diagnosed with schizophrenia during one year of treatment with Long Acting Injectable Paliperidone Palmitate. Method: The sample included a total of 59 outpatients schizophrenic patients from three Mental Health units in the province of Toledo (Spain) were recruited. The inclusion criteria were an age over 18 years, a diagnosis of schizophrenia (based on the ICD-10 criteria), the start of treatment with Long Acting Injectable Paliperidone Palmitate, and the non-utilization of any drugs such as hypnotics or sleep correcting agents. A series of demographic variables were recorded and the ISMI (Internalized Stigma of Mental Illness) scale was used to assess internalized stigma, while the DAI (Drugs Attitude Inventary) scale was used to evaluate the attitudes to medication The scales were again applied at baseline, 6 and 12 months after the start of treatment Intruments: The Drugs Actitude Inventary (DAI 30) is an established, reliable self-report instrument that evaluates patients' perceived effects and benefits of maintenance antipsychotic drug therapy. The Internalized Stigma of Mental Illness Scale (ISMI) assess different aspect of stigma . It was consist of twentynine items are grouped into five subscales Results: N=59 patients (34 males and 25 females), with a mean age of 42 years. There were 2 dropouts during the year of follow-up. The results showed an improvement in ISMI score during the 12 months, manifesting from the third month (ANOVA, $p<0.05$). Likewise, statistically significant differences (ANOVA, $p<0.05$) were observed with the DAI scale for; these results persisted over the year of follow-up and were manifest from the third month. DAI baseline 11,5 (SD 2,3), 11,8 three months (DS 2,4) and 12 months 12,7 (SD 2,1). Conclusions: In our sample of patients diagnosed with schizophrenia during one year of treatment with Long Acting Injectable Paliperidone Palmitate results of the study shows an improved attitude to the medication and internalized stigma.

No. 58

Right-Sided Intracranial Lesions in Active-Duty Service-Members Presenting With First-Episode Psychosis

Poster Presenter: Adrian Manuel Cuellar, M.D.
Co-Author: Laura Francesca Marrone, M.D.

SUMMARY:

Although primary psychotic disorders remain amongst the most disabling, costly and taxing ailments among the general population, there is little consensus as to what constitutes an adequate evaluation of a patient presenting with symptoms of first episode psychosis. The Psychiatric Transition Program, at Naval Medical Center San Diego, is the only first episode psychosis program within the Department of Defense located at one of the three Navy Military Treatment Facilities. Each service member presenting to this program undergoes an extensive laboratory and radiological examination to exclude medical causes that may be contributing to their current presentation and to address these reversible causes of psychosis if identified. This poster will examine three cases of active duty service members, each with no prior psychiatric history, who were found to have right sided temporal horn and para-hippocampal lesions during this evaluation. The discussion will highlight the impact of these lesions on the patients' initial

presentation and to what extent the lesions impacted their treatment while enrolled in the Psychiatric Transition Program. These cases demonstrate the critical importance of access to a multidisciplinary team including psychiatrists, psychologists, neurologists, radiologists, primary care physicians, case managers, and psychiatric technicians. A comprehensive approach to evaluation and work up prepared these service members transitioning to life outside of the military, which included establishing care with Veteran's Administration treatment programs and developing a transition plan for career and educational advancement.

No. 59

Acalculia and Right-Left Disorientation in Five Individuals Presenting With Psychotic Features Across Multiple Diagnoses

Poster Presenter: Adrian Manuel Cuellar, M.D.
Co-Author: Laura Francesca Marrone, M.D.

SUMMARY:

Gerstmann's syndrome and its constellation of symptoms including finger agnosia, left-right disorientation, agraphia and acalculia is a known entity within the fields of both neurology and psychiatry localized to the left angular gyrus. Here we present six individuals varying in age, ethnicity, and diagnoses who all presented with one similar characteristic being that of positive symptoms of psychosis in the context of either a primary psychotic disorder or mood disorder with psychotic features. Although these individuals suffered from either schizophrenia, bipolar disorder with psychotic features or major depressive disorder with psychotic features, they all demonstrated acalculia and left-right disorientation at the peak of their illness severity. As these individuals remained engaged in treatment, both talk therapy and pharmacotherapeutics, these issues resolved. These cases suggest a potential common etiology for psychotic symptoms across multiple diagnostic domains. Additionally, resolution of symptoms with treatment raises the question as to whether the causative etiology is secondary to hypoperfusion to this region or neurotransmitter imbalance regulated with antipsychotic regimens. We will discuss the comprehensive evaluation completed for each individual patient, elaborate on their treatment regimen, and propose future options for investigation regarding the role that the left angular gyrus may play in the formation of psychotic symptoms across multiple disorders.

No. 60

Management of Schizophrenia: An Educational Intervention

Poster Presenter: Ori-Michael J. Benhamou, M.D.
Co-Authors: Bora Colak, M.D., M.P.H., Saad Rahmat, Yuliya Hryb, M.D., Ifeoluwa Osewa, M.D., M.P.H., Alexander C. L. Lerman, M.D.

SUMMARY:

Schizophrenia is a chronic psychiatric disorder with a worldwide prevalence of 1.1%, independent of ethnic or economic background. Although there is no definitive cure, management of schizophrenia includes psychosocial and pharmacologic interventions. It is recommended that a pre-treatment assessment, focusing on factors that may be adversely affected by antipsychotic medications, be performed prior to initiating pharmacologic therapy. Educational Intervention: Disorder of the Quarter (DOQ): Schizophrenia is a 10-week didactic program designed to provide psychiatry residents training at WMC with relevant information regarding the epidemiology, biological bases for disease, DSM-V criteria, scientific data (including CATIE and CUTLASS trials), and management guidelines of schizophrenia spectrum disorder (primarily PORT and TMAP). Prior to this educational initiative, we reviewed charts to assess the management of schizophrenia patients at the Behavioral Health Center at Westchester Medical Center (WMC). One year later, following the DOQ, a similar chart review was conducted. Change in practice and adherence to recommendations were assessed. WMC Chart Review: A cross-section of patients (N=33) discharged from WMC in October and November 2016 with a primary diagnosis of Schizophrenia, or related Psychotic Disorder, was chosen for chart review. Average age was 30 years with a mean hospitalization stay of 39 days (3-92 days). 44% of the patients presented with substance abuse, with cannabis being most prevalent (31%). Patients were managed with a variety of antipsychotic medications: Risperidone 30%, Haloperidol 18%,

Quetiapine 18%, Olanzapine 12%, Clozapine 12%, Aripiprazole 12%, Perphenazine 9%, Fluphenazine 3%, and Lurasidone 3%. 82% of patients were discharged on SGAs (Second Generation Antipsychotics), 30% on FGAs (First Generation Antipsychotics), and 21% on multiple antipsychotics. 18% received Long-Acting Injectable antipsychotic agents. Patients with first hospitalization comprised 30% of the sample and were discharged on the following medications: Risperidone (40%); Quetiapine (30%); Haloperidol (20%); Aripiprazole (10%); combination of Quetiapine and Olanzapine (10%). Patients discharged on Clozapine had an average of 14 prior hospitalizations versus 2 for non-clozapine patients (p=0.0001). Although the post-DOQ sample was younger (p=0.0146), other demographic variables were not significantly different for gender, length of stay, recidivism, substance abuse, co-morbidity, BMI or Total Cholesterol. Treatment with SGAs was significantly increased (p=0.0165) post-DOQ. BMI as well as Heart Rate and Blood Pressure were collected in 100% of patients. Fasting Lipid panel and Hemoglobin A1c were collected in in 58% and 48% of patients, respectively. Following the education intervention, the choice of antipsychotic medication for Schizophrenia more closely followed best practice guidelines. However, there remains room for improvement, particularly in the collection of pre-treatment assessment metrics.

No. 61

Prodromal Tales of Teenage Dope

Poster Presenter: Peffin Lee, D.O.

SUMMARY:

Mr. M., an 18 year old male with past psychiatric history of unspecified depressive disorder and unspecified psychotic disorder, presented to the ED via police after being found sleeping outside in the middle of the night. His mother petitioned for involuntary hospitalization due to concerns of suicidal ideation with recent overdose of fluoxetine and bupropion. Involuntary admission to an inpatient mental health unit was pursed after the patient denied the content of the petition, rather stating his intention was to "get high." He presented with blunted affect, avoidant eye contact, vague speech with increased latency to response, and psychomotor retardation. He isolated to his room and was often found lying in bed. At other times he was found lying on the floor at the end of the hallway. He reported practicing "meditation" to heal himself. Serial MOCAs were completed showing deficits in attention, language, abstraction and delayed recall, He was restarted on olanzapine and sertraline which were titrated to 20mg PO QHS and 150mg PO daily, respectively, to target negative symptoms. Review of records showed Mr. M.'s first psychiatric hospitalization was one year ago in which he abstained from food and fluid to be closer to "God." He required a medical admission and placement of NG tube along with IV hydration. He was discharged into a partial hospitalization program affiliated with our hospital system. A diagnosis of major depressive disorder with psychosis vs schizoaffective was considered at that time. His second hospitalization, which was on our mental health unit, occurred nine months later in which he presented with thoughts that his mother had sexually assaulting him. Collateral was obtained from mother and father. Due to history of LSD and cannabis wax use along with several overdoses on antidepressants and ADHD medications, his outpatient psychiatrist reduced doses of psychotropics and recommended substance use treatment. Family meetings were held with each parent who expressed frustration with their son's lack of motivation in moving forward in life. We present a longitudinal case report of likely first break primary psychosis with persistent negative symptoms. The initial onset of depression and prodromal schizophrenia occur around the teenage years. Predominantly negative symptoms can be mistaken for major depressive disorder. However, course and prognosis of the former lead to poorer outcomes. The teenage years also mark a time for experimentation with psychoactive substances that may trigger or exacerbate underlying symptoms. Furthermore, the lack of motivation and decreased activity may lead others to think there is a defect in the individual's character or attributable to substance use rather than a consequence of the illness. In this poster, we discuss the challenges and importance of differentiating negative symptom etiology from depression, primary psychotic disorder, or induced by substance use.

No. 62

Early Detection and Management of Clozapine-Induced Myocarditis: A Case Report and Literature Review

Poster Presenter: Matthew Craig Parker, D.O.
Co-Authors: Phillip Arellano, M.B.B.S., Marc Katz, Swaiman Singh, Diane Edith Custer, M.D.

SUMMARY:

Background:Clozapine is an atypical antipsychotic medication with proven efficacy for treatment-resistant schizophrenia and suicidality reduction. A rare and potentially lethal side effect is clozapine-induced myocarditis. Its presentation is often overlooked in clinical practice due to its lack of specificity with regards to signs and symptoms. Case Description: A 40-year-old Caucasian male with a psychiatric diagnosis of schizophrenia was admitted to the psychiatric unit for worsening depression, suicidal ideation, and worsening auditory hallucinations. His medical history was significant for hypothyroidism, non-insulin dependent diabetes mellitus, Charcot osteoarthropy, and untreated chronic lymphocytic leukemia. Psychiatric medication on admission included ziprasidone for psychosis with past trials of other antipsychotic medications. Due to lack of efficacy in controlling psychosis and persistent suicidal thoughts, ziprasidone was gradually tapered and clozapine was started with steady dose titrations. While on a dose of clozapine 125 mg, the patient had a fever of 100.9 F and was tachycardic with a heart rate of 129 beats per minute. He experienced at times symptoms of shortness of breath and left-sided chest pain. When these signs and symptoms continued to persist, a medicine consult was obtained. A pulmonary embolism was ruled out with a negative CTA of the chest. Troponin level was significantly elevated at 5.12 ng/mL, indicating cardiac damage. The patient was transferred to the medical floor for continued management. An echocardiogram showed a reduced ejection fraction of 35-40% with global hypokinesia of the left ventricle and borderline dilation, a clinical picture consistent with myocarditis. Clozapine was discontinued and the patient was started on aspirin, an ACE-inhibitor, and a beta-blocker. Once medically stabilized, the patient returned to the psychiatric unit for continued care. Discussion: Myocarditis is a rare side effect of clozapine, with an estimated incidence rate of <0.1 to 1.0% during the first two months of treatment. The lack of specificity in terms of signs and symptoms contribute to this diagnosis often being overlooked. As a result, some researchers estimate the true incidence of clozapine-induced myocarditis to be much higher. Increased awareness of this side effect and its diagnostic indicators can help physicians detect early development of myocarditis and improve patient safety for patients taking this medication.

No. 63

Investigating Lupus Psychosis Versus Late-Onset Schizophrenia

Poster Presenter: PhuongTam Nguyen, M.D.

SUMMARY:

Introduction: The typical age of onset for schizophrenia is in late adolescence or early twenties, with slightly later onset in females. However, some studies have shown that 20% of primary psychosis can present after the age of 40. There are questions of validity when a diagnosis of schizophrenia is made in older patients since there are possibilities for alternative organic processes. Schizophrenia has an interesting association with systemic lupus erythematous because between 14% and 75% of patients with lupus are estimated to have neuropsychiatric symptoms and about 5% with hallucinations and delusions. Case report: This is the case of a 62-year-old Hispanic female with a past medical history of lupus and no previous psychiatric history who presented for self-neglect due to new onset psychosis. Since her mother passed away 9 months prior to presentation, she began having delusions of being impregnated by the spawn of Satan so she stopped eating in order to not feed it. She exhibited bizarre involuntary movements in her neck and shoulders, which she attributed to having electricity running through her and being controlled by a video game that her grandson plays. She subsequently unplugged all the electronics in the house. She would see a morphed face when she looked in the mirror, holes in her arms and multiple hands. CT and MRI head showed no acute changes. There were initial concerns for psychosis secondary to lupus cerebritis. Some inflammation markers, ESR and CRP, were elevated, however, her ANA was

negative along with the rest of the lupus panel. She was started on Risperidone. Within a week, she showed marked improvements in her delusions, hallucinations and involuntary movements that were appreciated by her family members. Conclusion: This case illustrates that schizophrenia, once thought to be an early onset disorder, can manifest late in life but often goes undiagnosed due to social isolation, cultural biases, reluctance from family.

No. 64

Catatonia and Incipient Neuroleptic Malignant Syndrome With Paliperidone: A Case Report

Poster Presenter: Rodney Uy, M.D.
Co-Authors: Yassir Osama Mahgoub, M.D., Jenna Hartman, D.O.

SUMMARY:
Catatonia and Incipient Neuroleptic Malignant Syndrome with Paliperidone. A Case Report Introduction: Neuroleptic malignant syndrome (NMS) is a life-threatening condition associated mainly to antipsychotic medications and occasionally with other psychotropics. Incipient NMS, a term used to describe clinical presentation suggestive of NMS but not meeting all the criteria, can pose diagnostic and treatment challenges due to the possibility of misdiagnosis and inappropriate management. Catatonia and NMS share similar clinical features and pathology. Previous reports have described the occurrence of NMS in catatonic patients treated with antipsychotics, suggesting its role in progression to NMS. Benzodiazepines are used for treatment of both catatonia and NMS which may alter the presentation of NMS to a milder form that could be missed. We present a case of incipient NMS with Paliperidone in a patient who developed catatonia during his treatment. Objectives: Highlight the need for careful management of psychotropic medication in patients with catatonia as symptoms overlap with NMS, which can delay diagnosis and treatment. Case report: 25y/o Chinese male with no past medical or substance use history. He has history of schizoaffective disorder and previous catatonia. He was admitted for manic symptoms. His medications on admission were Lithium 600mg PO BID, Clozapine total of 500 mg daily and Propranolol 20mg PO BID. Lithium titrated to 1500mg PO qhs and due to history of noncompliance, Clozapine was cross-tapered with Paliperidone and titrated to 12mg daily over 7 days. On day 7 he displayed catatonic symptoms of mutism, posturing, refusal of eating and drinking and was started on Lorazepam with dose increased to 6mg daily resulting in mild improvement. On day 8 on Paliperidone, CPK was 194 U/L. His temperature increased to 38 briefly and remained normal for the rest of the day. On day 9, CPK increased to 962 U/L and subsequently to 1735 U/L. There was no rigidity or fever to suggest NMS but he appeared to be more confused and had vital instability. Patient subsequently required transfer to medical service for IV hydration, IV Ativan and started on bromocriptine 2.5MG Q8hrs. All psychotropics were stopped and his confusion, CPK and vital instability improved and he was transferred back to inpatient psychiatry. His catatonia continued for another three weeks and treated with lorazepam. He was discharged on Clozapine. Conclusion: NMS can present as a spectrum with some patients developing milder forms that lack the expected vital instability. This can represent a clinical challenge for diagnosis. As catatonia shares similarity with NMS in terms of - symptoms, pathology, and treatment, discontinuation of antipsychotics and other medications such as lithium may be warranted upon emergence of catatonia as it may progress to NMS.

No. 65

An Investigative Diagnostic Complication: Schizo-Obsessive Disorder

Poster Presenter: Rose De Silva
Co-Author: Sarayu Vasan, M.D., M.P.H.

SUMMARY:
Introduction: A link between Obsessive Compulsive Disorder (OCD) and psychotic disorders has been well documented for several decades. Although, the clinical relationship or the specific subtype termed “schizo-obsessive” has not been clearly documented or understood, it has been noted in literature for many years as well. One hypothesis states that OCD may precede schizophrenia as a prodrome. However, that would mean OCD symptoms should remit, rather than persist when psychosis become apparent in a patient; this phenomenon is not observed. Thus, the specific subtype “schizo-obsessive” can be explained as coexistence of

obsessive compulsive symptoms (OCS) in schizophrenic patients. It is important to differentiate between the compulsions of OCS from repetitive delusional behavior in schizophrenia. Compulsions lack rational justification, although it is performed based on the obsessions, whereas repetitive delusional behavior is completely justified based on the delusion. Case: This case report describes a 64-year-old Caucasian male who presented with symptoms suggestive of schizophrenia and obsessive-compulsive disorder who responded to fluvoxamine and ziprasidone. Discussion and Conclusion: It is imperative to understand and learn more about schizo-obsessive subtype and to give its due respect as the prevalence rate of the disorder is observed to be 12.5% -25%. Hemron S et al looked at prevalence of OCS among hospitalized schizophrenic patients and concluded that 10% of schizophrenic patients had significant OCS related to both obsessions and compulsions and that OCS positively correlates to duration of illness. Another study revealed that prevalence of OCS in schizophrenic patients as high as 64% and about 30% of schizophrenic patients meet the Diagnostic and Statistical Manul of Mental Disorders (DSM) criteria to be diagnosed as OCD. The difference in prevalence of these two studies might be due to the differences in study methods. Nonetheless, an average prevalence of 12.5% - 25% of schizo-obsessive subtype is much higher than the prevalence of OCD and schizophrenia, individually. With the current available information, it is difficult to discern the incidence rate of schizo-obsessive disorder, mainly because such a diagnosis is not currently available in the DSM. Here, we put forth more evidence of schizo-obsessive disorder by presenting a case study that highlights the importance of identification and treatment of OCD in schizophrenia. By doing so, we hope to draw more attention to the subject and the need for clearer diagnostic guidelines for this specific subtype.

No. 66

A Longitudinal Follow-Up Study on Multiple Sleep Latency Test and Body Mass Index of Type 1 Narcolepsy Patients in Korea

Poster Presenter: Jihyeon Lee
Co-Authors: Yoo Hyun Um, Seung-Chul Hong

SUMMARY:
Background: Narcolepsy is a chronic disorder with numerous adverse long-term consequences, including increased comorbidities including obesity, high mortality rates and decreased quality of life. With emerging attention to the long term course of the disorder and importance of accurate diagnosis, diagnostic stability of multiple sleep latency test(MSLT), mostly frequently used to identify narcolepsy, is often challenged. Methods: In this study, we compared the baseline and follow-up demographic characteristics and body mass index(BMI) of type 1 narcolepsy patients. Moreover, results from repeated MSLT conducted on the 48 type 1 narcolepsy patients were compared, with mean follow up of nearly ten years. Results: BMI from the baseline to the follow-up visit was significantly increased in the participants. There were no significantly different parameter changes in MSLT results. Conclusions: MSLT has good test-retest validity in type 1 narcolepsy patients. Close surveillance for the detection and management of obesity is warranted in clinical settings. This study does not report any financial interests or potential conflicts of interest.

No. 67

Anorexia Nervosa in a Male Patient With Schizoaffective Disorder, Bipolar Type

Poster Presenter: John H. Jung, M.D.
Co-Authors: Joseph D. Zollo, M.D., Nadia Mohamed El Fangary, M.D., Ph.D., Julie A. Niedermier, M.D.

SUMMARY:
Mr. F. is a 37 year-old Caucasian male with a history of schizoaffective disorder, bipolar type, and anorexia nervosa, restricting type, who was found unconscious at home with a blood glucose of 20 mg/dL. His BMI was noted to be 13.3 kg/m^2. The patient was medically admitted to correct the electrolyte derangements of refeeding syndrome. He was then transferred to inpatient psychiatry for the treatment of psychosis and an eating disorder. The patient reported a delusion of external control, such that a “watchman” dictated his oral intake and negative perception of body image. Consequently, his food preparation and consumption while hospitalized alternated between ambitious and ascetic, including four days without eating. As the

patient failed to appreciate the life-threatening risk of his weight loss, his family obtained expedited guardianship. Goal BMI for discharge was set to be 16.1 kg/m^2, approximately halfway between his initial BMI and an ideal of 18.5 kg/m^2. The patient was treated with olanzapine and a regimented behavioral plan, with eventual weight gain and resolution of psychosis. The evidence behind the use of antipsychotics as treatment for anorexia nervosa remains limited. Of the antipsychotics, olanzapine has been more widely studied, with meta-analyses showing trends towards an increase in BMI with olanzapine over placebo. Mr. F represents a case where olanzapine was effective in treating both psychotic and eating disorder symptoms. As this case demonstrates, the two disorders may have overlapping neurobiological mechanisms, mutually reinforcing psychopathology, and treatment synergism that warrant further study.

No. 68

A Case Report of Seasonal Recurrent Brief Psychotic Episodes

Poster Presenter: Joseph Ipacs, M.D.

SUMMARY:

We describe a case of a 53 y/o Colombian female with a past history of panic disorder and more remote history of Bipolar Disorder diagnosed in Colombia who was taken to the Emergency Room by her 16 year old son because of a paranoid delusion that her ex-husband was threatening to harm them. Other than anxiety and decreased sleep, there were no other affective symptoms present. The patient would often have brief episodes of paranoia almost every year during the Spring or Summer, noting that she had one time fled to Colombia due to fear for her safety. She was diagnosed with Bipolar Disorder in Colombia, but further history showed no evidence of periods of mania or severe depression. There was no evidence of substance use or addiction. Most of her previous episodes spontaneously remitted without antipsychotic medication. Annual patterns have been observed with affective disorders (1) and clinical syndromes such as cycloid psychosis describe recurrent brief episodes of psychosis with recovery between episodes (2). This case illustrates an interesting example of the emergence of recurrent brief psychotic episodes linked to season of the year.

No. 69

Differentiating Pseudocyesis From Delusional Disorder in a Psychotic Patient

Poster Presenter: Joseph Tosto
Lead Author: Rosemarie Caskey, M.D.

SUMMARY:

Ms. H, a 24-year-old Caucasian female with no prior psychiatric history admitted to the hospital after attempting suicide in County Jail. She was given the diagnoses of unspecified psychosis, sedative hypnotic or anxiolytic use disorder, severe methamphetamine use disorder, and unspecified depressive disorder. The patient was exhibiting what appeared to be multiple fixed delusions, one of which being that she was pregnant. Routine urine pregnancy testing was completed on admission and repeated along with a pelvic examination and abdominal ultrasound to rule out alternate pathology. All tests were negative. The patient was informed of the negative results but continued to believe she was pregnant. The patient had gained approximately twelve pounds in one month with noted abdominal distention. Ms. H described somatic symptoms such as pelvic pressure and pain while endorsing symptoms of feeling a growing pregnancy within her uterus. The patient also reported that she had not had a menstrual cycle in eight weeks. Ms. H began to refuse her medications because she believed “it will harm my baby.” The patient’s Haldol Decanoate dose was increased and within three days, remarkable improvements were noted. The patient began to state “I just don’t feel pregnant anymore.” By the time of discharge, the patient nonchalantly revealed to the treatment team that she had a nexplanon birth control in her upper arm when asked if she planned to use a birth control method outside of the hospital but did not appear to make a conscious connection with her previous beliefs of pregnancy. In this poster, we define pseudocyesis and delusional disorder and discuss the challenges of differentiating the two in a psychotic patient along with scrutinizing psychological antecedents. Although there has been a distinction made between the two, there is still a line of demarcation that remains blurred.

No. 70

Clinical Outcomes in Schizophrenia Patients During First Years of Diagnosis: A Cohort Study

Poster Presenter: Juan Cano, M.D., M.Sc.
Co-Authors: Carlos Pedraza, Rodrigo Cordoba, M.D., Julian Ortegon, Alexie Vallejo

SUMMARY:
The first years after the diagnosis of schizophrenia are crucial for the establishment of parameters involved in the outcome and long-term remission. It is a risk period involving hazards like withdrawal from the general health system, relapses and suicide. This period also concurs with major challenges in development: stable identity, pair's network, vocational training and intimate relationships. Observational study of a cohort of 50 patients with a recent diagnosis of schizophrenia (within five years of baseline visit), followed up during at least three years and up to five years, with periodic evaluations every three months. No changes were made in therapeutic schemes. This registry has the objective to describe the clinical outcomes in this particular group of patients: relapses, total or partial hospitalizations, days free of symptoms; and to suggest possible factors related to that evolution. Diagnosis was confirmed with M.I.N.I. interview, we employed short instruments including Clinical Global Impression – CGI, Global Assessment of Functioning – GAF, and Personal and Social Performance Scale – PSP. Most patients were men, single with secondary school grades.80% of patients experienced prodromal symptoms with a median duration of 426 days (interquartile range – IR 90–914), patients expended a median of 423 days since the beginning of psychotic symptoms (IR 77–823), before the schizophrenia diagnosis were made. Before entering to the cohort, the patients had experienced a median of 2 psychotic episodes (IR 2–4), and 2 psychiatric hospitalizations (IR 2–4). The rate of substance use observed was 36% (Graphic 1). Most patients (96%) were treated with atypical antipsychotic, 16% were in treatment with depot medication, 64% of patients were receiving concomitant medications, and only 8% of patients were receiving non-pharmacological treatment. Satisfaction with medication was negative in 10%, neutral in 20% and positive in most patients (70%). Adherence was described by patient and relatives as high (mean 89%). At the end of the first year, the proportion slightly changed, turning negative in 15%, neutral in 22%, and positive in 63%; Meanwhile the adherence described continued high (mean 84%). Most patients were followed for at least three years, here we describe the relapse and survival rate. There were a higher proportion of males, which could not reflect exactly the whole spectrum of this population. It is noticeable the long period of time the patient spends with prodromal and psychotic symptoms before the diagnosis was made, especially regarding the known impact of the duration of untreated psychosis in the outcome of patients. There is a strong association between schizophrenia and cannabis, the rate of substance use observed in our cohort was 36%, higher than general population and like previous descriptions on literature. Most patients with schizophrenia will have at least one relapse within the first five years.

No. 71

Metacognitive Introspective Accuracy of Social Cognition as a Predictor of Functional Outcomes in Individuals With Schizophrenia

Poster Presenter: Juliet Silberstein

SUMMARY:
Background: Cognitive capacity, competence, and negative symptoms account ?50% of the variance in the functioning of individuals with Schizophrenia. Metacognitive introspective accuracy (IA) has emerged as a new lead. Impaired IA of neurocognition has been shown to be a potent predictor of functional deficits. This research expands on the functional significance of IA to social cognition (SC). Methods: Pearson correlations and regression analyses examined the association of IA in SC and four functional outcome domains. IA was indexed by the discrepancy between clinician(n=64) and patient(n=64) ratings on the Observable Social Cognition Rating Scale (OSCARs), and clinician-rated everyday functioning on the SLOF scale. We used block-entry analyses, entering all the performance-based measures followed by interview-based measures to compare the relative influences of performance-based measures of SC and social competence compared to IA on these same outcomes. Results: This analysis included 64 medically stable people with schizophrenia who had high-contact clinician informants (mean age=38.5,

63% male). There was generally a large effect size for clinician reports (all Pearson r =-.63 to -.38, p<.001) and a medium effect for IA across all functional outcomes (all Pearson r=-.45 to -.23, p <.01). Self-reports were correlated only with everyday activities (r= -.18, p<.05), SC competence only with work (r=.32, p<.001), and negative symptoms only with interpersonal (r=-.3, p<.001). Self-reported OSCARS scores did not significantly enter any of the regression analyses (all t<1.7, p>.09). Additionally, all four regression analyses found that the set of performance based tasks did not contribute as a group to any of the SLOF subscales (all F (7,120)<1.89, all p>.08). However, clinician-ratings predicted all functional domain after controlling for social cognitive performance, and IA was significant for 3/4 of the subscales. The R2 cumulative (clinician and IA) accounted for 31-44% of the variance in interpersonal, everyday activities, and work outcomes (all p =.001). For everyday activities, metacognitive IA did not factor into the model, and clinician ratings accounted for 14% of the variance (p=.001). Finally, clinician and IA SC added 32% of the variance in vocational outcomes accounted for by social competence (R2 incremental=.10, R2 cummulative= .42, all p=001) and 26% of variance accounted for in interpersonal outcomes by negative symptoms (R2 incremental = .09, R2 cumulative = .35, all p=.001). Conclusions: The present study suggests that accurate IA of SC is a stronger predictor of real-world social outcomes than SC capacity, competence, or negative symptoms. These findings also provide evidence that clinician ratings are helpful as a standard against which to judge the accuracy of patients' self-assessments, and may be a highly useful proxy for extensive neuropsychological testing.

No. 72

Expressed Emotion: An Underused Factor in Predicting Outcome of Patients With Psychosis?

Poster Presenter: Kalyan C. Kandra, M.D.
Co-Author: Jeffrey Ali

SUMMARY:

Despite major improvements in psychotropic medications since the advent of Chlorpromazine, identifying and applying factors known to impact outcome decision making in clinical psychiatry seem to be not always identified and taught in modern psychiatry residency training. Expressed Emotion (EE) has been established as such a factor not only in psychotic disorders like Schizophrenia but also in other mental health disorders. The consensus of such studies is that patients who live in families with high EE are more likely to relapse than those who live in families with low EE. This concept is often missed in today's heavily loaded biomedical environment and not always stressed in psychiatric training. Using details from recent encounters with patients who presented to a University Medical Center with psychotic symptoms and the impact of the Expressed Emotion (EE) of the family members of the patients, an attempt is made to correlate these factors with the course of care received by the patient. Using these experiences and a literature review suggestions as to how EE can be identified, evaluated and assessed, and used to improve patient outcome measures are made in this poster presentation.

No. 73

Delusional Parasitosis: Case Report and Review of Literature

Poster Presenter: Katherine Marie Edwards, M.D.
Co-Authors: Lauren Tran, M.D., Garima Singh, M.D.

SUMMARY:

Ms. X is a 61-year-old Caucasian female with a past history of anxiety disorder, major depressive disorder, alcohol dependence, and sexual abuse, with multiple comorbid medical conditions, who is followed in the adult psychiatry clinic for medication management. For several years, this patient has had delusional thoughts regarding "worms" or "bugs" crawling under her skin. These thoughts have recently increased in severity, resulting in frequent scratching and associated abrasions and excoriations on her skin. During clinic appointments, she ruminates on this issue, and shows her providers samples of hair, tissue, and dirt that she claims are bugs that she collected from her skin. She takes multiple pictures of her skin and self-inflicted wounds, using these as evidence that there are bugs on her skin, though without any indication that there are such insects present. Her symptoms are so significant that she awakens at night given reported itching, and eats canned food given concern for

contamination with these parasites. This patient's symptoms have been treated with multiple medications in the past, including combinations of venlafaxine, duloxetine, citalopram, bupropion, lamotrigine, aripiprazole, risperidone, and olanzapine at various times. Her most recent medication has been fluoxetine for depressive symptoms, and quetiapine was added to her regimen for additional anti-psychotic coverage at her most recent clinic visit. While the exact prevalence of delusional parasitosis is unknown, studies have found that this disorder occurs primarily in Caucasian middle-aged or older women, though it has been identified in all age groups and in males. This disorder may be primary, secondary, or organic in origin, representing either a primary psychotic disorder, a disorder associated with another mental disorder (such as schizophrenia or depression), or a disorder secondary to an organic illness. Patients typically experience a perception that small parasites are crawling or burrowing into their skin, and often initially present to non-psychiatric medical professionals. Treatment of this disorder often requires the use of anti-psychotic medications, though additional treatment may be needed based on comorbid mental or organic disease. While randomized trials are limited, available evidence suggests that remission rates are equal with both typical and atypical anti-psychotic medications. In this case presentation, we discuss a patient with this rare illness, and review available literature regarding the treatment and management of delusional parasitosis. Additional information regarding effective treatment of this disorder, especially in patients with multiple comorbid medical conditions (such as this patient), is important given that most patients first present to non-psychiatric medical professionals.

No. 74

A Case of Treatment-Resistant Schizoaffective Disorder That Responded to an Extended Trial of Paliperidone Palmitate

Poster Presenter: Kathleen Margaret Ward, M.D.
Co-Authors: Bilal Ahmad, M.D., Kathleen A. Crapanzano, M.D., Jessica McGovern, Melissa A. Watson, M.D.

SUMMARY:

Schizoaffective disorder is a chronic psychiatric illness believed to be on a continuum between schizophrenia and mood disorder, with features of both. This is a case of a patient with schizoaffective disorder who was treatment resistant and could not tolerate clozapine but responded to high dose paliperidone palmitate (PP) over time. SW, a 25 year-old African American male with a long history of mental illness, presented to the psychiatric emergency department with agitation, violent behavior, thought blocking, and was observed responding to internal stimuli. For the first five months of his admission, trials of oral paliperidone, olanzapine, and lurasidone in conjunction with low dose PP were initiated with no success. Throughout most of the hospitalization, SW continued to have both positive and negative symptoms of psychosis including hallucinations, inappropriate laughter, flat affect, poor hygiene, and being socially withdrawn. A clozapine trial was prohibited by his low neutrophil count (ANC= 1,300 cells/mL). The patient was evaluated with the Montreal Cognitive Assessment Version 7 (MoCA), Brief Psychotic Rating Scale (BPRS), Positive and Negative Syndrome Scale (PANSS), and Brief Negative Symptom Scales (BNSS) three times throughout his treatment course, prior to the initiation of PP 234 mg, as well as at 7 weeks and 9 weeks post-initiation, by a doctoral level graduate student trained in the administration of these instruments who was not familiar with the case. Assessments and ratings were made blind to changes in treatment. Three months after initiation of PP 234 mg antipsychotic monotherapy, and nine months after admission, SW was discharged to a group home. His final evaluation yielded a 73% improvement in his MoCA score from baseline, a 9% improvement in his BPRS score, a 31% decrease in his PANSS score (which represented a 33% drop in his positive symptoms score and a 28% drop in his negative symptoms score), and an 18% improvement in BNSS. SW's case demonstrated the use of high dose PP in stabilization of a patient who was both treatment resistant and unable to tolerate clozapine. In addition to responding to antipsychotic monotherapy with high dose PP, SW was provided time in an acute inpatient psychiatric unit to respond. This case provides an addition to the literature on PP use in refractory schizoaffective disorder in addition to highlighting the importance

of patience for pharmacotherapy to achieve its desired effect.

No. 75

Safety Precautions and Discharge Planning of Patients With Factitious Homicidal Ideation

Poster Presenter: Maria Teresa Carvajal, M.D.
Co-Authors: Luisa S. Gonzalez, M.D., Janani Udaya-Shankar, Joseph Sokpagna Soeung, M.D.

SUMMARY:
Factitious Disorder is a disorder in which a patient intentionally feigns physical or psychiatric symptoms, without a means for secondary gain, to assume the 'sick patient' role. Symptoms may be subjective, such as pain, suicidal or homicidal ideation, making it challenging to determine intentionality and whether it is fully or partially intentional (1). Homicidal Ideation consists of thoughts or considerations of killing another, which may range from an idea to a well-thought out and detailed plan. Studies have indicated that the prevalence of violence in patients with untreated severe mental illness that present with psychosis or delusions can be elevated and can lead to frequent hospitalizations. Guidelines on how to safely discharge a patient who presents with factitious homicidal ideation from the inpatient setting to the community are limited. Here, we describe the case of a 62-year-old male with schizoaffective disorder and poly-substance abuse who had delusions of factitious homicide. The patient verbalized, on several occasions, committing homicide in 1991 for which he claimed to have spent 12 years in jail and being on parole. Collateral history determined that the homicide and time spent in jail had never occurred and were the result of the patient's delusions. This patient's factitious homicidal ideations led to frequent hospitalizations and discharge planning challenges. This case aims to provide clinicians with recommendations for the safe discharge planning of patients who present with factitious homicidal delusions, with the objective of decreasing length of stay and hospitalizations.

No. 76

Acute Psychosis in a Patient With Treatment Noncompliant Graves Disease: A Case Report

Poster Presenter: Sidra Ghafoor, M.D.
Co-Author: Sindhura Kunaparaju, M.D.

SUMMARY:
Thyrotoxicosis has been associated with various psychiatric symptoms such as anxiety, mood lability, depression and rarely psychosis. The link between acute psychosis and thyrotoxicosis especially in the context of Graves Disease is poorly understood. Herein we report a case of a 41-year-old Caucasian female with a psychiatric history of bipolar I disorder and post traumatic stress disorder, with a medical history of Graves Disease, Hypertension, Degenerative joint disease and Chronic headaches. She initially presents to the psychiatric emergency department with recent onset of confusion, bizarre behavior, and delusions of paranoia. Majority of the history was obtained from patient's husband. He reported that patient stopped attending psychiatric appointments and had been only intermittently compliant with psychiatric medications: Abilify and Lamictal. Additionally, she had stopped taking her medications for hyperthyroidism and hypertension for at least three months. Of note, patient had previously refused I-131 treatment preferring to continue taking Methimazole (or PTU). Over the last three to four weeks prior to admission, patient began exhibiting paranoid behavior and poor reality testing. Per husband, she endorsed severe anxiety and mood lability. Once admitted to the psychiatric unit, her treatment was complicated with only partial response to antipsychotics. Various differentials were considered such as Bipolar I Disorder (most recent episode mania with psychosis), schizoaffective disorder-bipolar type, psychosis secondary to a general medical condition (thyrotoxicosis), substance induced psychosis, and acute psychosis not elsewhere classified. Patient's treatment course improved as her underlying thyrotoxicosis was corrected with PTU. In this poster, our goal is to discuss the importance of recognizing psychosis as a manifestation of thyrotoxicosis particularly with Graves Disease. Further, given that psychosis is a rare complication in hyperthyroidism, accounting for only 1% of cases it raises both diagnostic and therapeutic challenges and consequently necessitates collaboration between specialists for optimal care.

No. 77

Folie à Deux: Case Report of a 59-Year-Old Female With Factitious Disorder Who Was the Associate in a Shared Delusion Spearheaded by Her Daughter

Poster Presenter: Sidra Ghafoor, M.D.
Co-Authors: Jessica Elizabeth Healey, Richard Stark, Consuelo C. Cagande, M.D.

SUMMARY:
Shared psychotic disorder, also known as folie à deux, is a rare clinical syndrome that involves an ill patient, the "inducer", who transmits delusions or psychosis to another person or people who may share these in part or whole. The shared disorder often occurs in individuals who have close relationships, such as members of the same family and commonly between females. The secondary individual is usually passive, highly suggestible, and may have traits of a histrionic personality disorder. Factitious disorder is defined as a disorder wherein the patient misrepresents medical or psychiatric symptoms or even injures himself/herself without the intent to gain an external reward. Factitious disorders can also occur when one person imposes symptoms on another individual. The signs and symptoms are typically imposed by a parent on a child; however, the reverse may occur. This report describes a case of a fifty-six-year-old female patient who presented to Cooper University Hospital with progressively worsening neurological symptoms and complaints of chronic pain after sustaining injuries from chiropractic neck manipulation over twenty years ago. At her daughter's insistence, an extensive workup at multiple hospitals was performed. The daughter was constantly researching potential conditions, asking questions, and dominating conversations. Additionally, the daughter often threatened to take legal action against members of the healthcare team when they did not comply with her demands regarding the treatment of her mother. Despite an exhaustive search, no physiological basis explained the patient's symptoms. Recognizing delusional disorders that exist in patients, and potentially family members of the patients is important because of the impact on the patient's life and medical system. Although diagnoses of exclusion, delusional disorders and somatic disorders can result in prolonged hospital stays and expensive medical workups if left undiagnosed. When treating patients with these disorders, it is imperative to set strict boundaries and adhere to them. It is also important to meet with the patient on a regular basis, limit the number of medical tests performed, and educate the patient on his/her illness. This report will illustrate a unique case of factitious disorder and folie a deux as well as highlight the importance of an accurate diagnosis and educate the reader on management of these complex and rare conditions.

No. 78

HIV-Related Psychosis and the Challenge of Finding Causality for Acute Psychotic Episodes

Poster Presenter: Tarek Aly, M.D.
Co-Authors: Nauman Ramay, M.D., Asghar Hossain, M.D., Shiyao Wang

SUMMARY:
The Human Immunodeficiency Virus is associated with psychosis in a multitude of avenues. Finding causality for a newly decompensating psychosis is intensely challenging in these patients as the medications, the virus' impact on the CNS itself, and subsequent opportunistic infections may all cause psychiatric manifestations. We present a case challenge reflecting the multi-factorial assessment and management in the case of a 44 year old Mexican-American man experiencing a one day history of severe mood lability and florid psychosis. We outline the initial Emergency Room Workup, CT Scan/MRI findings, and the pertinent negative findings which eventually led to the conclusion that his psychosis was likely antiretroviral induced. As the patient's work up was slowly and meticulously gone through, the patient's behavior and psychosis continued to occur in a "waxing and waning" nature so abrupt that his unpredictability required constant observation for the majority of his stay and frequent assessment of his psychotropic regimen. We present an example of these types of acute changes in mental status as reflected in his attempt to fill out a voluntary admission form (pictured in the poster itself).

No. 79

The Switch Between Ego-Dystonic and Ego-Syntonic Thinking to Predict Decompensation in Overlapping OCD and Schizophrenic Symptoms: A Case Report

Poster Presenter: Tarek Aly, M.D.

Co-Authors: David Schwartz, M.D., Asghar Hossain, M.D., Dyman Kwarciak

SUMMARY:
It is important for clinicians to be aware of the co-occurrence of obsessive-compulsive and psychotic symptoms in order for patients to receive early identification and treatment of both disorders. The term "Schizo-Obsessional Disorder" has been referred as an area of overlap of the syndromes and we will present a case exemplifying this overlap and co-occurrence. We present the case of a 28 year old Indian-American male who was diagnosed with Obsessive Compulsive Disorder in his late teenage years which manifested as a severe preoccupation with germophobia, infection, and uncleanliness. The symptoms were ego-dystonic and the patient sought treatment to regain functioning in his daily life (school, relationships, work, etc). His symptoms were managed on first line medications (SSRIs) until the age of 26 when his obsessions and subsequent compulsions became ego-syntonic, his insight into his illness faded, and his compulsions for hand-washing excessively changed to being unable to move, sit, lay on a bed, shower, eat, or leave his home. His need to stand in order to prevent himself from coming into contact with germs/bacteria led him to develop severe bilateral lower extremity lymphadema. When stabilized, his obsessions/compulsions again became ego-dystonic and he regained day-to-day functioning. He was again seen in the local psychiatric emergency room 6 months later with a similar presentation reflecting a pattern of psychotic decompensation starting initially with a worsening of his chronic OCD symptoms. We present his assessment, course of hospitalization, stabilization and treatment regimen in order to remind clinicians on the identifiable overlap of OCD and Schizophrenia or "Schizo-Obsessional Disorder."

The Man Who Lost His Memory and Personality: A Case of Frontotemporal Degradation and the Challenging Aspects Therein

Poster Presenter: Tarek Aly, M.D.
Co-Authors: Javeria Sahib Din, Asghar Hossain, M.D.

SUMMARY:
Frontotemporal dementia (FTD) is a divergent group of neurodegenerative conditions. It is a prevailing cause of young-onset dementias and remains a challenging diagnosis for physicians due to its overlapping characteristics with other psychiatric and neurologic illnesses. It is characterized by the progressive atrophy involving the frontal and the temporal lobes, which may present in a multitude of varying presentations. Of them includes "Behavioral Variant FTD," leading to severe behavioral changes. Among the behavioral symptoms, the earliest symptom to appear is a personality change5. Altered eating habits, apathy, disinhibition, emotional blunting, obsessive symptoms etc. are next5 to appear. Sexual inappropriateness is common in FTD. The symptoms which are least to be seen in bvFTD are hallucinations and aggressive behavior. We present the case of a 59 year old Hispanic male with a sudden change in personality and a 6 month history of severe cognitive decline who presented to the local psychiatric emergency room after being found wandering next to a local bridge. He presented with critically severe memory loss, being unable to recall his name, where he lived, or any other vital information. After medical clearance, a CT scan of the brain indicated unique frontal and temporal degradation of the brain. We present his challenging clinical management, unique presentation, and stabilization during his course of hospitalization.

No. 81

Dual Cases of Topiramate-Induced Hair Loss

Poster Presenter: Tarek Aly, M.D.
Co-Authors: Sameerah F. Akhtar, M.D., Zohaib Majid, Shabber Agha Abbas, Asghar Hossain, M.D.

SUMMARY:
The association of anti-epileptic medication with resultant alopecia is frequently reported especially relative to valproic acid and carbamazepine use. Topiramate, a second-generation anti-epileptic, is highly effective in the treatment of seizure disorders and for the prophylaxis of migraine headaches. It has also shown promise for the treatment of bipolar disorder, obesity, and anti-psychotic-induced weight gain. Topiramate side effects are mainly central nervous system related including dizziness, somnolence, psychosis, cognitive impairment, word-

finding difficulties, and weight loss. Till date, alopecia has only been anecdotally reported as an adverse effect of topiramate bipolar therapy. Hair loss, and in particular alopecia, can have significant cosmetic impact and psychosocial effects in children and in young adults. Drug-induced hair loss is characterized as diffused, non-scarring and is usually reversible with drug cessation. We report on two cases where patients developed alopecia following topiramate dose escalation of similar ages, symptoms, and response to improving the hair loss.

No. 82

The Importance of Early Recognition of Depakote-Induced Pancreatitis in the Acute Hospital Setting

Poster Presenter: Tarek Aly, M.D.
Co-Authors: Nauman Ramay, M.D., Asghar Hossain, M.D., Shiyao Wang

SUMMARY:

Pancreatitis associated with the use of valproic acid has been a well documented complication and adverse event that can be life threatening to patients of both psychiatry and neurology. The diagnosis of the pancreatitis is made in the clinical setting via the classical signs and symptoms of the syndrome (epigastric abdominal pain, nausea, vomiting, abdominal distension, fever, malaise, etc). There are a plethora of articles and case reports published, further establishing the classically taught association between the medication and the syndrome, however a further emphasis needs to be placed on how effective monitoring, communication, and thorough physical examination can lead to a life-saving intervention. We present the case of 41 year old Caucasian male with an extensive, life-long history of hypomanic symptoms presenting with severely decompensating symptoms of mania. During his first admission, he was stabilized on a regimen of only Risperidone. He was stabilized on the acute involuntary unit of Bergen Regional Medical Center and later discharged. He returned to the ED within 2 weeks with a resurgence of his manic symptoms. At this time, he was started on a regimen of Valproic Acid and Risperidone. Approximately 24 hours after starting the medication the patient developed the classic signs and symptoms of pancreatitis. Due to effective communication between the emergency department senior resident, admitting psychiatric intern on the hospital floor, and medical team attending, the syndrome was diagnosed, addressed, and managed appropriately.

No. 83

Psychostimulant Abuse in the Schizophrenic Patient: A Case Report

Poster Presenter: Tarek Aly, M.D.
Co-Authors: Asghar Hossain, M.D., Syed Saleh Uddin, M.D.

SUMMARY:

Cognitive decline and negative symptomatology is a life altering and debilitating feature of Schizophrenia that has been well described historically. Though the relationship between substance abuse and schizophrenia is a multifactorial amalgam of complex causality vs. correlation, psychostimulant abuse would logically be a potential danger to address the cognitive decline of the disease itself. Stimulants, themselves, are one of the most abused drugs in the USA, often assessed to be the second most common type of prescription medicine abused. Stimulant abuse therein can lead to psychotic symptomatology when abused, and in an already schizophrenic patient, the assessment, treatment, and stabilization is challenging. We present the case of a 26 year old Korean ex-law student with a history of schizophrenia and recent diagnosis of stimulant use disorder presenting to the local psychiatric emergency room after substance-oriented intervention prevented him from easy access to regularly prescribed psychostimulants. He subsequently ordered psychostimulants derived from these regularly prescribed medications from overseas retailers in Russia. He began abusing Adrafinil (prodrug of Modafinil) and Phenylpiracetam as a powdered form for approximately 1 week in unspecified amounts.. He began to experience severely decompensating psychosis including visual, auditory and tactile hallucinations as well as persecutory delusions and severe mood lability. We present the initial assessment, management and stabilization of this patient.

No. 84

An Anti-GQ1b Syndrome With Persistent Psychiatric Symptoms

Poster Presenter: Forhad Ullah

Co-Authors: Catherine Velupillai, Douglas Opler, M.D.

SUMMARY:
Background: Anti-GQ1b antibody is found in Miller Fisher Syndrome (MFS), a subtype of Guillain Barre Syndrome (GBS). GBS causes ascending muscle paralysis. MFS is an acute idiopathic polyneuritis that causes ophthalmoplegia, ataxia, and loss of tendon reflexes. The similar Bickerstaff Brainstem Encephalitis (BBE) is also associated with anti-GQ1b. BBE is similar to MFS, but includes brainstem encephalitis. It is unclear if BBE is a separate entity or a variant of the same process. However, in anti-GQ1b syndromes, patients are not known to have persistent psychiatric symptoms. We present a rare case of anti-GQ1b syndrome with persistent psychiatric symptoms. Case Report: A 33 year old woman with anti-GQ1b brainstem encephalitis was admitted for facial abscess. Psychiatric consultation was requested to evaluate her behavior and decision-making capacity. History revealed that 2 years ago, she was highly functional and worked as a bus driver with no physical or psychiatric symptoms until she was first hospitalized for 2 weeks of lethargy and apathy. At that time, she would intermittently respond to questions and became bedbound. MRI without contrast at that time showed T2 hyperintensities in midbrain, pons, basal ganglia, genu of the corpus collosum, and medial temporal lobes with patchy enhancement in basal ganglia. LP showed lymphocytosis. Anti-NMDA and anti-GQ1b were initially negative. Diagnosis of autoimmune brainstem encephalitis was made based on MRI. She deteriorated and stopped responding. With IV methylprednisolone and plasmapheresis, she improved and was discharged to a rehabilitation facility. Repeat labs revealed anti-GQ1b. Over the 2 years since presentation she was hospitalized for multiple episodes of poor oral intake and aggression. Her mother reported that she is angry, steals from the home, and invites strangers over. During this hospitalization, she was selectively mute, often communicating via hand gestures, yet intermittently spoke clearly, stating that she does not know why she misbehaves. Admission labs revealed hemoglobin of 9.5 g/dL and potassium of 3.2 mmol/L (corrected with PO potassium). Urinary toxicology screen was negative for drugs. Patient was started on antibiotics for her dental abscess and quetiapine 25 mg PO BID for her impulsivity. She was discharged to outpatient psychiatric care.
Discussion: MFS and BBE present with ophthalmoplegia, ataxia and loss of tendon reflexes. BBE, as in this patient, also includes brainstem encephalitis. Both MFS and BBE are anti-GQ1b with similar neurological manifestations. Patients with GBS often have acute hallucinations, vivid dreams, and anxiety, yet these psychiatric symptoms tend to resolve in days. Long term psychiatric issues have not previously been reported in these syndromes, which makes this case remarkable. Little is known about long term consequences of anti-GQ1b syndromes. This case adds to the body of knowledge on psychiatric sequela of these syndromes.

No. 85

Management of TBI-Induced Psychosis of Epilepsy With Anticonvulsants as Long-Term Monotherapy

Poster Presenter: Gayatri Baker

SUMMARY:
Management of Psychosis of Epilepsy following Traumatic Brain Injury with Anticonvulsants as Long-Term Monotherapy. Author Gayatri Baker, D.O. Abstract K.A. is a 20-year old Caucasian female with no previous psychiatric history presenting to outpatient urgent care clinic with new onset auditory hallucinations. She describes hearing multiple voices conversing with one another and belonging to unknown individuals. The voices are occasionally commanding in nature and patient reports that they instruct her to not consume food or trust others. Symptoms began 1 week ago and were preceded by insomnia, anxiety, racing thoughts and diminished appetite. With further evaluation of patient's history, it is revealed that she incurred head trauma during a MVA 6 months prior. She notes that in the weeks following the MVA, she also experienced progressive blurred vision. Following the MVA, she received no medical attention as she reported that she was inebriated at the time and was fearful of legal consequences. Patient was unable to contract for her personal safety due to progressively worsening features of anxiety in the context of new onset auditory hallucinations. Patient was hospitalized to undergo further evaluation and management. Initial laboratory work up returned normal. EEG was abnormal and demonstrated

epileptiform focus overlying the temporal region suggestive of simple focal seizure activity. Symptom chronology and onset after incurring TBI point toward psychosis of epilepsy rather than primary psychosis of schizophrenia. Had proper history not been acquired at the time of admission, the patient could easily have been diagnosed with Schizophrenia and treated incorrectly with antipsychotics alone, rather than in combination with an antiepileptic. In this poster, the challenges and importance of proper evaluation and simplified treatment approaches in the management of psychosis of epilepsy (POE) are discussed in detail. The outcomes of this case demonstrate that prognosis can be improved if treatment is focused on underlying cause rather than control of overt psychotic symptoms.

No. 86

New-Onset Obsessive-Compulsive Disorder and Subacute Cerebellar Stroke

Poster Presenter: Jacob Joseph Oyer, M.D.
Co-Authors: Rebecca A. Olufade, M.D., Walter Kilpatrick

SUMMARY:

Background: Cerebellar Cognitive Affective Syndrome (CCAS) refers to a constellation of deficits in the domains of executive function, spatial cognition, language, and affect resulting from damage to the cerebellum. For patients, these deficits range widely in type, duration and severity, and may include an increase in obsessive thinking and/or compulsive behavior. We present the case of a 30-year-old man who developed a new-onset Obsessive-Compulsive Disorder (OCD) in close temporal proximity to a subacute cerebellar stroke. **Methods:** An exhaustive Pubmed and Medline search was performed to explore clinical characteristics, pathophysiology, and potential treatments of CCAS, as well as the relevant neurobiology involved in OCD. Lastly, we explored other documented neuropsychiatric manifestations of cerebellar pathology. **Results:** A 30-year-old man, diagnosed 4 weeks previously with new-onset OCD, and 2 weeks previously with subacute cerebellar stroke secondary to antiphospholipid antibody syndrome, presented to our emergency department with complaint of abdominal pain and hematuria. During hospitalization, Psychiatry consulted for evaluation and management of extreme distress around obsessional fears (e.g., that he may contract HIV from unclean surfaces, develop cancer, or become a pedophile) and compulsive behaviors (e.g., hand-washing) that he reported had become more frequent and intrusive over the past several weeks. His evaluation was part of a multidisciplinary effort involving workup by Medicine, Neurology, Surgery and Hematology. Review of MRI brain from outside hospital showed multiple small areas of infarction in the posterior lobe of the left cerebellar hemisphere. Psychiatric evaluation found no other evidence of current mental health issues; past history was significant for long-term issues with untreated generalized anxiety. GI pain and hematuria were determined to be secondary to bleeding associated with his coagulation disorder. He was treated with escitalopram with good effect on follow-up. Original studies of CCAS describe multiple patients with new-onset obsessions, compulsions, and stereotypies. Literature review reveals at least one similar case involving a 52-year-old woman who developed new-onset OCD in the setting of arachnoid cyst in the left-side, posterior cerebellum. Structural MRI studies have consistently shown volumetric differences in several cerebellar regions (left Cruz I, left IV, right VI, and Vermis VI) between OCD patients and healthy controls. Functional MRI studies have also shown altered connectivity between cerebellar, neocortical, and limbic regions in OCD patients. **Discussion:** Cerebellar damage may cause new or worsening deficits in multiple cognitive and affective domains. Symptoms may present as new-onset psychiatric illness such as OCD, and fall within the greater domain of CCAS. This is supported by multiple studies highlighting the role of the posterior cerebellum in cognitive and affective modulation, and is in accord with the concept of cognitive or affective “dysmetria” in posterior lobe damage, analogous to the motor dysmetria resulting from damage to the frontal lobe. **Conclusion:** It is important for psychiatric providers to recognize the neuropsychiatric consequences of cerebellar injury. Cognitive, affective and behavioral changes may occur in patients with lesions involving the posterior lobe of the cerebellum, and may overlap with a variety of DSM 5 depressive, anxiety and autism spectrum disorder. Successful management has

involved use of SSRIs, antipsychotic agents, and neuropsychological rehabilitation programs.

No. 87

A Case of Delayed Post-Hypoxic Leukoencephalopathy in a Catatonic-Appearing Patient

Poster Presenter: Jordan Lea Gaal, D.O.
Co-Author: Meredith Lee Bentley, D.O.

SUMMARY:

Objective: To broaden the differential diagnosis for catatonic-appearing patients lacking typical improvement with benzodiazepines to consider delayed post-hypoxic leukoencephalopathy. Introduction: Catatonia is a neuropsychiatric syndrome characterized by the presence of cognitive, motor, speech, and behavioral symptomatology. Mutism, staring, posturing, and catalepsy are some of the most well-known signs but clinical presentation varies dramatically. Various scales, such as the Bush-Francis Catatonia Rating Scale, help gauge severity and assist with diagnosis. Treatment is most often with a benzodiazepine. It is well known that other conditions such as akinetic mutism, status epilepticus, locked-in syndrome, and stroke may mimic catatonia. Differentiating catatonia from other conditions requires careful history, examination, and selected laboratory or neuroimaging findings. Delayed post-hypoxic leukoencephalopathy (DPHL) is a syndrome of cerebral demyelination following hypoxic brain injury. After the initial hypoxic event, there is a non-sustained return to baseline function lasting days or weeks but is ultimately characterized by rapid decline in neurobehavioral function. For some patients, the clinical presentation is primarily parkinsonian but others display symptoms consistent with akinetic mutism. Establishing the diagnosis can be a challenge due to the delayed nature of symptom onset and limited laboratory and neuroimaging options early in the course of illness. Magnetic resonance imaging (MRI) is often normal upon hospital admission but reflects leukoencephalopathic changes later in the disease process. Either subtype of DPHL has high symptom overlap with other more commonly encountered clinical conditions and diagnosis requires a high index of suspicion. We present a case of DPHL presenting with akinetic mutism originally misdiagnosed as catatonia. Case: A 50 year-old with history of depression was found unresponsive, hypoxic, and febrile in her home for unknown duration. Computed tomography (CT) of the head and MRI of the brain were initially normal. Liver function tests, amylase, and lipase were elevated and acute pancreatitis was suspected. Once stabilized, her cognition improved to baseline. Ten days into hospitalization, her condition deteriorated until she displayed symptoms of mutism, stupor, staring, decreased oral intake, and perseveration. Catatonia secondary to major depressive episode was suspected. Lorazepam was started and titrated upward without result. Lack of response to lorazepam prompted repeat MRI of the brain, revealing diffuse white matter changes in frontal, temporal, parietal, and occipital lobes. DPHL was diagnosed. Conclusion: Delayed post-hypoxic leukoencephalopathy should be considered for patients with catatonia-like symptoms who do not respond to a trial of lorazepam and whose presentation involves a hypoxic event with return to baseline cognition and then followed by neurobehavioral decline.

No. 88

ECT to Treat Psychosis in a Patient With Severe TBI

Poster Presenter: Julia F. Jacobs, M.D.
Co-Authors: Christopher W. Harris, D.O., Ryan Bradford King, M.D.

SUMMARY:

This is a report of a 47 year old former Marine admitted to an inpatient neuropsychiatry unit with three weeks of new onset, progressively worsening episodic paranoia and depersonalization seven years after sustaining a severe traumatic brain injury (TBI). The patient had no personal history of psychiatric disorders prior to his severe TBI in 2010 due to an ATV accident. However, he had a history of multiple mild and moderate TBIs from combat. The worst was in 2007 and was complicated by central hypoandrogenism, hypothyroidism, and hypocortisolism. The hypothyroidism and hypocortisolism ultimately resolved. After his severe TBI in 2010, the patient reported anosmia, two episodes of tonic-clonic seizure: one in 2009 and one three months prior to admission. Additionally, he

had one prior psychiatric hospitalization in 2015 for depressed mood, irritability, and suicidal ideation where he was diagnosed with a mood disorder due to a known physiological condition. Since that admission and subsequent discharge in 2015, his symptoms were well controlled with lamotrigine 250 mg BID, bupropion 300 mg daily, and regular psychotherapy. At the time of this admission, the neurologic exam was positive for chronic anosmia and subtle left-sided difficulty with rapid alternating movements. The mental status exam was notable for presence of paranoid delusions characterized by suspicion that others were talking about the patient or wanted to kill the patient leading to debilitating panic attacks. Laboratory values were only notable for chronic low testosterone. MRI showed a left inferior frontal contusion with encephalomalacia and gliosis consistent with prior TBIs. Spot EEG showed one epileptiform spike in the frontal lobe, while continuous EEG did not show epileptiform activity associated with episodes of paranoia. Lamotrigine was increased to 300 BID for increased mood stabilization and antiepileptic effects. The patient then underwent 7 ECT treatments with dramatic improvement in his symptoms. He was discharged with scheduled outpatient ECT and psychiatric follow up. This case illustrates an evolving mood disorder with new onset psychotic features arising seven years after TBI. Additionally, it demonstrates the efficacy of ECT for the treatment of psychotic features in the context of a severe TBI. Finally, it emphasizes the importance of medical providers' awareness of the possible long-term psychiatric sequelae of TBI.

No. 89

Unique Challenges Faced by Male Patient With X-Linked Adrenoleukodystrophy in the Forensic Mental Health Care System

Poster Presenter: Kim Fielding
Co-Author: Simon S. Chiu, M.D., Ph.D.

SUMMARY:
B.B, a 25 year old Caucasian male, was diagnosed, along with his twin brother, with X-linked adrenoleukodystrophy (ALD) in early childhood. He presented to the Forensic Mental Health Care System in 2016 with a five year legal history including multiple charges for sexual assault, uttering threats, theft, possession of illegal substances, and harassment. His psychiatric presentation included symptoms of psychosis with delusional thinking, significant mood lability, impulsivity, verbal and physical aggression and sexual disinhibition. He was initially admitted under a Treatment Order after being found Unfit to Stand Trial. Despite multiple medication trials including the use of anti-psychotics and mood stabilizers, B.B. remained Unfit to Stand Trial and was placed under a Detention Order by the Ontario Review Board. He remains in a seclusion room at the forensic psychiatric hospital due to ongoing impulsivity and sexualized behaviours. He is deemed to be a significant risk to others due to his continued aggression and poor judgment, which is thought to be secondary to his ALD. Although B.B. previously used substances including crystal methamphetamine, this is not a current contributor to his presentation given his prolonged admission and lack of access to illicit substances. At this time, there are no community placements available that would be suitable for the level of care and supervision that B.B. requires. During the course of his admission, he experienced his first epileptic seizures, which were ultimately attributed to progression of his ALD. B.B. remains capable to consent to treatment, but requires assistance with eating and bathing due to significant restlessness and distractibility. In this poster, we review the various phenotypes associated with ALD and, in particular, the psychiatric manifestations of this illness. To our knowledge, this is the first case report of ALD presenting as psychosis, on a background of ADHD, substance use disorder and violent criminal behaviour. We also explore the unique challenges faced by patients with a neurodegenerative illness in the Forensic Mental Health Care System, for which treatment is limited and prognosis remains guarded. The findings also call into question whether genetic data is admissible as evidence in criminal court proceedings. Ethical issues in the context of palliative forensic psychiatry will be discussed, including the interplay between criminal culpability and therapeutic jurisprudence in the context of irreversible incompetency to stand trial.

No. 90

Aggressive Screening for Anti-NMDA Receptor

Encephalitis? A Case Report of a Nonspecific Psychiatric Presentation Leading to a Delay in Treatment

Poster Presenter: Lauren Solometo, D.O.
Co-Author: Marie Lyse Turk, M.D.

SUMMARY:

Despite the growing body of literature surrounding Anti-N-methyl-D-aspartate receptor (anti-NMDA-R) encephalitis, this disease remains challenging to diagnose, particularly in the absence of a prodromal headache, fever, or viral-like process. Readily available imaging, laboratory, and exam findings are non-specific. The diagnosis is confirmed by CSF and serum antibodies to the NR1 (also known as GluN1) receptor, testing which is not available at many institutions and requires a minimum of several days for results to return. Delay in diagnosis is thought to lead to worsened morbidity and mortality. We report the case of a 27-year-old female with a past psychiatric history of obsessive-compulsive disorder and no past medical history who was transferred from an outside psychiatric facility to the neurology service for management of progressive psychosis, with suspicion for limbic encephalitis. Psychiatry was consulted for assistance with determining the nature of her psychotic symptoms given the limited definitive evidence to suggest limbic encephalitis. Further workup was significant for positive plasma NR1 antibodies, which resulted several days after admission to our facility. In total, her treatment was delayed for approximately one month from the onset of psychosis. This case illustrates the challenges in diagnosing anti-NMDA-R encephalitis in the absence of the characteristic syndrome and specific laboratory findings. Further research about the underlying disease process is needed in order to optimize screening and prevent delays in treatment.

No. 91

A Case of Psychosis and Capgras Syndrome Following an Intracerebral Hemorrhage of the Right Basal Ganglia

Poster Presenter: Michele Vargas, M.D.

SUMMARY:

The patient is a 56 year-old African American man without previous psychiatric history and a medical history notable for poorly controlled diabetes mellitus 2 and hypertension, cerebellar ischemic stroke, and recent hemorrhagic stroke of the right basal ganglia complicated by seizures who presented to the psychiatric consult service with behavioral changes. He had recently visited his primary doctor who initiated therapy with sertraline (Zoloft) for irritability and aggression. Following his hemorrhagic stroke, the patient remained preoccupied with thoughts that his wife was being unfaithful and that his home was being invaded. He also developed an inability to identify his wife, often believing that she was an imposter, consistent with a diagnosis of Capgras Syndrome. He became increasingly aggressive, throwing objects around the home and threatening family members with knives. The psychiatry team attributed his symptoms to levetiracetam (Keppra) induced psychosis as the timeline coincided with the initiation of this medication. Recommendations were made to discontinue levetiracetam in favor of valproic acid (Depakote) for seizure prophylaxis, and the patient was discharged after an overnight observation on the neurology floor. He returned to the emergency department several days later after again threatening his daughter with a butcher knife. The patient was then admitted to the psychiatry service for management of post stroke psychosis which gradually improved with the addition of an antipsychotic medication. This case illustrates the importance of early detection and treatment of psychotic symptoms that emerge subsequent to a brain insult. It also demonstrates that the location and type of stroke strongly influences behavioral presentations, and provides a possible localization in the brain for the etiology of Capgras syndrome.

No. 92

Clinical Profile of a Male With Xenomelia and Intense Desire to Amputate a Healthy Leg Perceived as Alien to His Body

Poster Presenter: Mihir Ashok Upadhyaya, M.D., Ph.D., M.P.H.

SUMMARY:

Xenomelia, literally meaning “foreign limb,” is a neuropsychiatric condition in which apparently non-psychotic individuals have an intense, persistent belief one or more of their limbs does not belong to their body; instead they regard it as an alien

appendage that should be discarded. This unwavering fixed belief resembling a delusion is often debilitating to the point where the affected person strongly desires amputation of the unwanted limb. Traditionally, such a request is often denied by the medical community, causing some who suffer from the condition to attempt risky self-amputation, or to injure the limb in a manner that makes subsequent amputation medically necessary. (Upadhyaya & Nasrallah, 2017) The name for this condition has evolved over the years, depending on the emphasis given to certain of its characteristics. It was once called apotemnophilia, meaning "love of amputation," when the condition was thought to be a fetish involving sexual gratification derived from being an amputee. (Sedda, 2014) The term "body integrity identity disorder" (BIID) was introduced several decades later to incorporate it into a broader spectrum of accepted psychiatric pathologies, reasoning the condition was the cause of a mismatch between objective and subjective body schema, similar to anorexia nervosa or body dismorphic disorder. (Blom, 2012) However, unlike these other disorders, individuals with this condition have sufficient factual insight to know they appear "normal" to others. The newest term, xenomelia, was established to acknowledge the neurological component of the condition, after neuroimaging studies showed structural changes to the right parietal lobe of afflicted individuals who desired amputation of their left lower limb, thus linking the part of the brain that processes sensory input from the affected limb. (McGeoch, 2011) While particular nuances in symptomatology were modified in formulating these names, certain hallmark features have always remained the same. (Nowakowski, 2016) (1) It is established that the condition starts in early childhood, prior to puberty. (2) Those who suffer from it feel intense distress, and are resigned to the notion that nothing else can alleviate their condition except for amputation. (3) It is overwhelmingly more common in males than females. (4) It is accompanied by non-traditional attitudes about disability, with admiration of amputees and complete apathy and disregard toward the impairment that amputation would cause. While there are insufficient numbers to say it with complete confidence, the trend in the published literature would suggest that the lower left limb is predominantly the one implicated in the condition, in right-handed individuals. (Upadhyaya & Nasrallah, 2017)

No. 93

An Unusual Case of Arnold-Chiari Malformation Type I Associated With Psychosis

Poster Presenter: Miriam Quinlan
Co-Author: Sarayu Vasan, M.D., M.P.H.

SUMMARY:
INTRODUCTION & OBJECTIVE: Arnold Chiari Malformation (ACM) is a congenital brain anomaly characterized by herniation of cerebellar structures through the foramen magnum. Often, the diagnosis is a challenging one as presentations can vary from no symptoms to a wide variety of symptoms, and the manifestations can often be associated with other neurological and psychiatric conditions. To date, there is a paucity of literature pertaining to psychiatric illnesses associated with ACM. CASE PRESENTATION: After a comprehensive chart review, we report the case of a 34-year-old Hispanic male with Type I Arnold-Chiari Malformation and significant past medical history of psychosis, schizoaffective disorder, and severe bilateral visual impairment secondary to glaucoma. This unusual case highlights how ACM can be associated with psychosis. DISCUSSION: In assessing the overall quality of life and psychiatric morbidity in patients with ACM-I, researchers have found a psychiatric condition serves to affect not only the patient's physical health but also serves to damage the psychological, social, and environmental aspects of health. It is our aim to highlight how integral it is in psychiatric clinical practice to continue to investigate the patient globally and further, to investigate the neuropsychiatric implications of ACM. CONCLUSION: This case illustrates how the presence of a psychiatric syndrome in patients with overlapping neurological disease can serve to alter a symptom pattern, or delay a diagnosis, and therefore compromise identification and treatment for both conditions. Psychiatric symptoms should be explored in ACM patients to allow better detection of psychosis and anxiety disorders. Continual efforts should be made in order to investigate the neuropsychiatric associations of ACM, as they are

essential in improving both patient experiences and outcomes.

No. 94

Inpatient Treatment Challenges: Patient With Schizophrenia Who Develops Lewy Body Dementia

Poster Presenter: Monika Gashi, M.D.
Co-Authors: Luisa S. Gonzalez, M.D., Kyle Andrew Mihaylo

SUMMARY:

Lewy Body Dementia affects 1.3 million Americans. (1) It accounts for 15% to 35% of dementia cases, which is easily confused with Alzheimer's dementia that is the most common type of dementia due to old age. (2) When a diagnosis of Lewy body dementia is delayed or incorrect, inadequate treatment can increase the patients morbidity and mortality. The overlap or lack thereof of cognitive, psychotic, and motor symptoms often makes diagnosis confusing. During an psychiatric inpatient admission, treatment of the medical comorbidities, can be challenging and can potentially lead to increase in length of stay. We present a case of a 73 year old patient with a long history of schizophrenia who had been evaluated on multiple occasions at the emergency department (ED) for over a year prior to her psychiatric inpatient admission. She would present to the ED with paranoid symptoms, auditory and visual hallucinations, cognitive decline, and bizarre behavior which had been different from her previous admissions. After a prolonged length of stay, extensive laboratory, imaging studies, and several patient encounters, the patient was finally diagnosed with Lewy Body dementia and appropriate treatment initiated. This poster aims to demonstrate the importance of early recognition of the Lewy Body Dementia (LBD) symptoms when a patient presents to the emergency room with atypical presentation. A review of the psychiatric presentations , treatment trials, and potential guidelines that can be utilized in a collaborative effort between different disciplines to facilitate care and minimize the length of stay on inpatient service will be presented.

No. 95

Cognitive Dysfunction as Initial Neuropsyhchiatric Presentation of Multiple Sclerosis

Poster Presenter: Nazneen Shakeel, M.B.B.S.

SUMMARY:

Multiple sclerosis (MS) is the most common and disabling disease of the central nervous system affecting young and middle-aged adults, with a reported age of onset between 20 and 40 years. Although much of the burden of the illness is recognized as neurological, neuropsychiatric symptoms are sequelae of this debilitating disease. Cognitive impairment is a common phenomenon occurring in 53% to 65% of patients and varying from relatively mild to rarer presentations that might appear as dementia. It is unclear if severe cognitive impairment in a young adult can represent the first presenting neuropsychiatric symptom of MS. Most of the neurological deficits in MS are attributed to white matter lesions. In more recent times, particularly with advances in neuroimaging, gray matter pathology has been considered as a more plausible explanation for cortical deficits in MS. It has been noted that cognitive problems can be present when the neurologic examination does not identify deficits. On occasions, neuropsychiatric symptoms have been the initial reasons patients seek clinical attention. Methods: We reviewed the literature and could not find clear cases of cognitive impairment as a presenting neuropsychiatric symptom of MS. Results: We present a case of a 28 year old single male. Five years prior to presenting to our clinic, the patient was taken to a local mental health center for forgetfulness and falling spells with no prior medical or psychiatric illness. He was diagnosed with schizophrenia after reporting auditory hallucinations. He received treatment with risperidone for one year. He continued to follow up at the local mental health center, from where he was referred to a University Neurology Clinic for "evaluation of memory problems and seizure-like spells". During the neurological work up the patient was referred to psychiatry ambulatory service for neuropsychiatric evaluation. Extensive neurological work up revealed a diagnosis of Multiple Sclerosis while the follow-up assessment at our psychiatry clinic revealed the patient to have significant cognitive impairment. The case presented is used to highlight the cognitive dysfunction of a severe type determined by neuropsychiatric, neuropsychological testing, neurologic and neuro-imaging techniques

detected in this patient. The possible clinical correlations with evaluative findings and known neuroscience knowledge as well as possible management options are also presented, with suggestions for future studies. Conclusions: This case presents a diagnostic dilemma for practicing psychiatrists evaluating such patients with a complex neuropsychiatric presentation. Psychiatrists face challenges in the management of such patients given the limited treatment options for dementia or "dementia-like" deficits.

No. 96

Conversion Disorder? … Think Again!

Poster Presenter: Nicole Abbot, M.B.B.S.
Co-Author: Kathy M. Bottum, M.D., Ph.D.

SUMMARY:

Introduction: Conversion Disorder (CD) is a syndrome of neurological symptoms with no proven organic cause. Despite advances in imaging studies, the diagnosis of CD is largely clinical and remains a diagnosis of exclusion. Case Presentation: 56 yr old lady with history of rheumatoid arthritis, hypothyroidism and migraines, but no psychiatric history, developed sudden onset of expressive aphasia and right sided numbness and weakness. Brain imaging was normal. Family declined TPA since symptoms started to improve. Aphasia persisted and a repeat MRI and LP was done which were normal. Psychiatry diagnosed her with CD, and commenced alprazolam, citalopram and aripiprazole. She was admitted readmitted one week later with continued aphasia and new onset left visual field defect. Brain MRI showed pachymeningeal enhancement, EEG showed no epileptiform waves, and second LP was done with CSF autoimmune panel, 14-3-3 protein, T-Tau protein, RT-QuIC all negative. Aphasia improved but incompletely and she was discharged. Eight days later she was readmitted with confusion, agitation, and visual and auditory hallucinations. Physical exam was significant for left visual neglect and new cognitive impairment. Repeat EEG showed triphasic waves. Valproic acid was started for presumed seizure activity. Consult liaison team diagnosed delirium, and treated with PRN haloperidol. Aripiprazole was later stopped, citalopram and valproic acid were tapered. She was treated with methylprednisolone, followed by IVIG for presumed autoimmune encephalitis. Cerebral angiogram did not show evidence of vasculitis. Her cognition and neglect improved and she was discharged to rehab. Follow up MRI brain showed focal T2 flair abnormalities. Brain tissue was biopsied and showed proliferation of ganglion cells in a background of nonspecific reactive changes. Discussion: Misdiagnosis of CD after extensive investigation is thought to be uncommon. CD is diagnosed more in female gender and comorbid psychiatric illness. Lack of a clear neuro-anatomical pathway to explain presentation or a lack of supporting neuro-imaging, are often attributed to CD, which DSM-5 cautions against. In our case, lack of acute psychological stress, psychiatric history and comorbid autoimmune disorder suggested an alternative diagnosis. Current literature recommends avoiding repeated imaging however, this revealed the evolution of a pathological process. Advances in fMRI demonstrate abnormalities in motor and sensory cortices, the limbic system and ventromedial prefrontal cortex in patients with CD. This challenges the theory of a purely psychogenic etiology for CD. Future research should lead to better understanding and management of CD. Conclusion: CD is a diagnosis of exclusion and should be considered with less haste in the acute care setting. Continued follow up is essential to avoid misdiagnosing a neurological disorder.

No. 97

Anti-NMDA Receptor Encephalitis in a Patient With a History of Autism Spectrum Disorder

Poster Presenter: Xavier Yang Diao, M.D.
Co-Author: Milana Mor, M.D.

SUMMARY:

OP is a 16-year-old male with a past medical history of mild persistent asthma and a psychiatric history of attention deficit hyperactivity disorder and autism spectrum disorder who presented with a 3-day history of acute-onset altered mental status, seizures, and slurred speech. His brain MRI was unremarkable but EEG was significant for epileptiform discharges. Laboratory studies were significant for with serum- and CSF-positive NMDA antibodies, with a serum NMDA IgG titer of 1:2,560. Imaging including thyroid and testicular ultrasounds, as well as CT scans for chest, abdomen, and pelvis,

were all negative for occult malignancy. The child psychiatry consult-liaison service was consulted for significant agitation and behavioral dyscontrol. At that time, the patient was status post intravenous methylprednisolone, 3 days of intravenous immunoglobulin, and 2 infusions of rituximab, without significant clinical improvement. We recommended 1:1 observation for safety, quetiapine titrated by 50mg daily to clinical effect, clonazepam 3mg TID, and trazodone 50mg qHS for sleep. Intramuscular chlorpromazine 25mg TID prn was also added for acute agitation. The patient had a protracted hospital course, complicated by multiple episodes of agitation initially refractory to low-dose antipsychotics and decreased oral intake requiring a percutaneous endoscopic gastrostomy tube for enteric nutrition. Eventually, the patient defervesced to fewer episodes of agitation, relative resolution of his encephalopathy, and improved nutritional status. He was subsequently discharged to an acute rehabilitation facility for continued stabilization and therapy. Here we demonstrate a case of anti-NMDA receptor encephalitis in a patient with autism spectrum disorder. There is ongoing literature to suggest that patients with ASD have evidence of neuroinflammation—or by definition, encephalitis. It remains to be seen if the relation between encephalitis and ASD is uni- or bidirectional, that is: whether children with ASD have a genetic diathesis to developing encephalitides (such as those mediated by the NMDAR), or conversely, if deranged or inflamed neuroreceptor processes are implicated in the development of ASD. Further research is thus critical to developing targeted therapies for NMDAR encephalitis in patients with comorbid ASD, as well as for NMDAR encephalitis in neurotypical patients without a discrete focus for autoimmunity and molecular mimicry, i.e. ovarian or testicular teratomas.

No. 98

When Mood Swings Mean So Much More in the Oldest Surviving Case of ROHHAD Syndrome

Poster Presenter: Zohaib Haque, M.D.

SUMMARY:

Mr. C is a 23-year-old Hispanic Male with a past medical history of ROHHAD syndrome (Rapid-onset Obesity, Hypoventilation, Hypothalamic Dysfunction, and Autonomic Dysregulation), stroke at age 10 that left him quadriparetic, a Neuroendocrine tumor of the spinal column removed at age 12, pancreatitis, ARF, and osteopenia who presented to our outpatient clinic for “mood swings” and increasingly repetitive speech and confusion all displayed over the last 10 months. Before we could obtain prior records and new imaging studies for his follow-up visit he presented to the ER two weeks later with a seizure-like episode, and given his persistently altered mental status and inherent medical complexity he was admitted to the ICU. The differential diagnoses in considering this patient’s management were new-onset epilepsy, a cerebrovascular accident, metabolic abnormalities (both inherent and medication-induced), or a new sequela of his existing chronic medical condition. Mr. C’s tumultuous twelve-day hospital stay allowed us to monitor his symptoms and behavior during various stages of treatment, thus giving us a more comprehensive understanding of his complicated illness. In conjunction with the Neurology and Endocrinology team we decided to treat the patient with Levetiracetam for its lack of cross-reaction to the patient’s numerous medications, it’s anti-epileptic profile, and its mood stabilizing potential. On outpatient follow-up, the patient’s behavior and confusion have improved, and his epilepsy is well controlled as well. There are only about 150 reported cases of ROHHAD in the world with the vast majority of those afflicted dying in early adolescence, this makes our case unique and pertinent to the continuing care and survival of this patient population. Current ROHHAD research is primarily focused on determining the etiology of ROHHAD, whether they are epigenetic or autoimmune, and the best modalities of treatment in early childhood. This poster will discuss the various obstacles we faced in differentiating potential psychiatric etiologies from medical causes for his altered mentation and behavioral changes in an adult ROHHAD patient.

No. 99

Using Aloe Vera to Treat Seizures: A Case Study

Poster Presenter: Nina Jaffarzad, M.D.
Co-Author: Kathleen A. Crapanzano, M.D.

SUMMARY:

Interictal psychotic phenomena, particularly hallucinations and delusions, are common in patients with epilepsy. The prevalence of epilepsy-related psychoses (ERP's) in refractory epilepsy is 17.5% and are generally not associated with epilepsy characteristics such as the presence of a lesion or epilepsy type.1 They can occur ictally, interictally, postictally, as an alternative psychosis (patients who become psychotic when the seizures are well controlled), and as a result of antiepileptic medications. Ms. Y is a 64 year old female with history of intractable epilepsy, diagnosed at age 12, poorly controlled after multiple medication trials and an implanted vagal nerve stimulator. Pt began having mood symptoms and psychotic symptoms around the age of 30. Although the details of her psychiatric history are unclear and there are no available records, she reports multiple psychiatric hospitalizations during her life time with depression and psychotic symptoms. There is no family history of depression or psychosis. When she experiences psychotic symptoms, she has command hallucinations and paranoia. They occur interictally. Most recently, she was hospitalized twice in 2013 and diagnosed with Psychotic Disorder secondary to a medical condition and eventually stabilized on paliperidone and sertraline, along with lacosamine, zonisamide, clonazepam, and lamotrigine for her seizures. An EEG performed in March 2013 revealed the presence of interictal epileptiform activity in the right frontal temporal area. Although her depression and psychotic symptoms remitted, she continued to have seizures, 2-10 times per month. Her Paliperidone was gradually tapered from a maximum of 6 mg per day to 1.5 mg per day with no recurrence of her psychosis. In November of 2017, she began drinking daily Aloe vera juice to help with "belly fat". Over the next 9 months, her seizure frequency significantly dropped. In the 9 months prior to starting the Aloe vera, she was averaging 3.8 seizures per month. In the 10 months following the initiation of the Aloe vera, she averaged 0.3 seizures per month while only being treated with lamotrigine 100 mg twice a day. Aloe vera has been cultivated for health and medicinal uses for many years. Aloe vera has been demonstrated to have antidiabetic, anti-inflammatory, anti-oxidant, immunomodulatory, antineoplastic and neuroprotective properties.2 Animal studies have demonstrated a dose dependent depressive effect on neurotransmission,3 a positive effect on memory and depression,4 and a significant protective effect on the development of kindling while also raising the seizure threshold.5 There is no evidence to support Aloe vera playing a role in the treatment of psychosis or seizures in humans. However, inflammation6 and oxidative stress7 are believed to play a role in the pathophysiology of psychosis, schizophrenia and bipolar disorder.

Neuropsychiatric Manifestations Associated With Dyke-Davidoff-Mason Syndrome

Poster Presenter: Pooja P. Shah, M.D.
Co-Author: Smit Shah, B.A.

SUMMARY:
Dyke- Davidoff- Mason Syndrome(DDMS) is a medical condition characterized by cerebral hemiatrophy, compensatory cranial vault thickening; enlargement of cranial sinuses and ipsilateral falcine displacement along with numerous capillary malformations. Patients usually present with behavioral anomalies including aggressive behavior, seizure and mental retardation along with acute neurological symptoms like seizure and facial asymmetry. Our patient is a 26-year-old African-American female with autism spectrum disorder, reported history of anoxic brain injury, unspecified bipolar disorder, oppositional defiant disorder, seizure disorder on Saphris, Oxcarbazepine, Lamotrigine, clonidine at baseline who lives in a group home setting with constant 3 staff to individual patient support system with increased aggression and self mutilating behavior. On appearance patient was morbidly obese, minimally communicative she was alert oriented to name, her mood was irritable, her affect was flat and her behavior was not cooperative. Her speech was abnormal as she was only able to repeat few words. Thought process was limited. She denied any suicidal or homicidal ideations, denied delusions, denied any auditory or visual hallucinations. Insight and judgment were poor. Head MRI was consistent with Microcephaly, Sequela of chronic bilateral Anterior Cerebral Artery/Middle Cerebral Artery watershed territory infarcts with greater involvement present in the left hemisphere, associated with asymmetric

left-sided hemiatrophy (Dyke-Davidoff-Masson syndrome) and bihemispheric ulegyria, proptosis, prominence of bilateral lacrimal glands, diffusely diminutive appearance of the intracranial vasculature. This condition which was described in early 1930's for the first time and is being presented in the form of a case report and a review. The goal is to discuss imaging and behavioral manifestations along with associated differential diagnosis including Sturge Weber Syndrome and Encephalitis.

No. 101

Cyclical Vomiting Syndrome: Etiology, Pathogenesis, Differential Diagnosis, and Management

Poster Presenter: Pooja P. Shah, M.D.
Co-Author: Smit Shah, B.A.

SUMMARY:

Cyclic vomiting syndrome (CVS) is defined as severe vomiting attacks which have a sudden onset but recur periodically with a duration lasting from hours to days. On most occasions CVS self limits themselves. During attacks, signs including nausea, abdominal pain, photophobia, fever, pallor, dehydration, excessive saliva secretion and social isolation may accompany vomiting. Patients are completely healthy during the period between attacks. There is no laboratory or radiological finding which can explain the disease. It has been reported that the attacks may last for hours and days and the disease may last for months and years. The reasons of cyclic vomiting syndrome have not been elucidated fully yet. Hypersensitivity of the hypothalamo-pituitary-adrenal system and autonomic dysfunction in the autonomic system, disorders related with ion channels and mitochondrial disorders (like in migraine) and psychological factors have been blamed in the etiology. There is no clear consensus on the treatment of the disease. Life-style changes which target a decrease in the triggering factors, supportive therapies during attacks and prophylactic drug therapies are used. The information related with especially prophylactic treatment is limited, though various pharmacological agents are used. In this article, we present a case of a 21 year old female patient who was treated successfully with fluoxetine which is a selective serotonin re uptake inhibitor used in prophylactic treatment of CVS was presented. Etiology, pathogenesis, differential diagnosis and management have been discussed.

No. 102

Challenges Encountered While Managing Delirium in a Patient With PANDAS

Poster Presenter: Pooja P. Shah, M.D.
Co-Author: Smit Shah, B.A.

SUMMARY:

Ms. T is a 51 year old female with history of anxiety disorder, uterine cancer, congestive heart failure, fetal alcohol syndrome, skin picking disorder, gastroesophageal reflux disease, hypothyroidism, mental retardation, psychosis, schizoaffective disorder, bipolar type presented to ED with change in mental status, periorbital edema, aggression, combativeness and put in 4 point restraints. Her condition initially worsened with deterioration of mental status, combativeness, had purulent excoriating lesions over bilateral eyes and developed new onset unsteady gait. CPK was ordered with concerns of NMS and noted to be 1182. Antipsychotics were discontinued and patient was started on iv hydration. A thorough workup for delirium was performed including RPR, TSH, B12 and CT scan. ASO titres and Anti- DNAse B were ordered which demonstrated Streptococcal infection. CT scan showed vermian hypoplasia unchanged from her prior CAT scan. Patient was treated with IV antibiotics and IV hydration which significantly improved her symptoms in the next few days which was conclusive of PANDAS. CPK was downtrending. Pediatric autoimmune neuropsychiatric disorders associated with streptococcal infections (PANDAS) is a hypothesis that there exists a subset of children with rapid onset of obsessive-compulsive disorder (OCD) or tic disorders related to Group A- beta-hemolytic streptococcal infection. Being that most patient's fail to vocalize the symptoms it is important to have a high index of suspicion in patients with skin picking disorder. Etiology is a possible autoimmune reaction which interferes with basal ganglia functioning.

No. 103

Cushing's-Induced Psychosis: A Case Report

Poster Presenter: Pooja P. Shah, M.D.

Co-Author: Smit Shah, B.A.

SUMMARY:
Cushing's Psychosis is an interesting medical condition that presents with typical features of Cushing's syndrome in addition to psychiatric manifestations including hypervigilance, depression, mood dysregulation and anomalies in sleep and cognition. Various models have been used to explain these psychiatric manifestations mostly suggestive of cortisol induced dysfunction of the neocortex and hippocampus which have high density of cortisol receptors. Hereby we present a case of Cushing's psychosis in a 41 year old female. Patient presented with symptoms of claiming that her ex-husband tried to kill her and that she feels very upset because she is not allowed to see her two kids. Patient endorsed homicidal ideations towards her ex-husband and stated that she would formulate a plan to execute it. Patient was only able only to provide us with her ex-husband's first name and had difficulty recalling his last name. Patient has significant problems with her speech related to an expressive aphasia. She perservated stating "I am not allowed to do so". She denied suicidal ideations on the ground that " she is not allowed to do it, since my ex-husband is controlling me ". She reported being in an abusive relationship and ex-boyfriend was trying to kill her. Denied access to firearms or weapons. On physical examination, patient was morbidly obese with a classic moon face, buffalo hump, hirsutism and reddish- purple skin discoloration on the abdomen and thighs bilaterally. On lab evaluation, 24 hour serum cortisol was found to be severely elevated. Other causes of psychosis were ruled out. Consequently the diagnosis of Cushing's induced psychosis was made which ultimately resolved over one week of time. In this poster we will describe the medical management, diagnostic tests and differential diagnoses which were utilized in management.

No. 104
Ataque De Nervios—Etiology and Differential Diagnosis: A Case Report
Poster Presenter: Pooja P. Shah, M.D.
Co-Author: Smit Shah, B.A.

SUMMARY:
Patient is a 37 year old divorced religious Dominican spanish speaking female brought to ED after acute onset of bizarre and combative behavior. Collateral elicited from patient's sister. Per sister, shortly after dinner, patient began talking gibberish, different language that was unheard stating, " demons are beating me up" and were trying to take he with them. It was associated with multiple somatic complaints including chest pain, arm pain, headache, feeling cold and diffuse body aches. Sister reported that patient had similar symptoms a few years ago which resolved after " reading the bible" and that she had sustained a stab wound while she attempted battling the demons then. The current episode did not resolve despite reading the bible. Sister reported that the beliefs were related to spiritual considerations. She denied any recent stressors. Denied any prior travel. She affirmed that patient understood only Spanish and that her current dialect was not familiar with her place of origin. Patient had no recollection of the events that led to her hospitalization. In this poster we have highlighted the possible etiological causes and correlation of culture bound phenomena including childhood trauma, anxiety disorder, panic disorder and affective dysregulation. She reported feeling exhausted and reports having an out of body experience. Increasing awareness of differences in culture manifest as psychological distress which heralds focusing on the correlation between culture specific illnesses and psychiatric diagnoses. Culture bound phenomena warrant a thorough evaluation of assessment of stress and trauma history.

No. 105
Takotsubo Cardiomyopathy: A Diagnostic Dilemma
Poster Presenter: Pooja P. Shah, M.D.
Co-Author: Smit Shah, B.A.

SUMMARY:
Patient is a 65-year-old Caucasian female with past medical history significant for breast and uterine cancer, chronic wounds in the bilateral lower extremities secondary to venous insufficiency on chronic antibiotic suppression, hypertension, hypothyroid who presents to ED with complaints of worsening chest discomfort unrelated to exertion. History is consistent with multiple prior inpatient admissions in the last 6 months with similar

complaints. Each episode was noted to occur after the death of a family member and patient was discharged on Aspirin and statins with recurrence of symptoms. EKG was consistent with anterior wall MI. Troponins were negative for cardiac ischemia. Patient underwent cardiac catheterization which showed diffuse coronary vasospasm. Coronary Angiogram did not reveal any blockage of the coronary arteries. Echocardiogram showed cardiac apical ballooning. Patient was evaluated by psychiatry for mood lability. Patient stated that she had lost four family members in the last six months and had witnessed a hurricane while she was on vacation. Patient was unsure of her life span due to the progression of malignancies. Patient stated that her mood is fair, has no appetite and does not sleep and only "cat naps" at night. She feels depressed since she is unable to keep up with the things that that she could do previously. Patient stated that all her life she had been a provider to her 12 siblings. She considered herself, " mother to my siblings" after the death of her mother. She feels guilty of not being able to save her sisters who died of cancer and is letting people down. Takotsubo cardiomyopathy is a rare form of non ischemic cardiomyopathy where there is a sudden weakening of the muscles of the heart. Rightly known as the 'broken heart syndrome', Stress could be a major contributing factor in the pathogenesis of Takotsubo Cardiomyopathy.

No. 106

Intranasal Insulin: A Promising Treatment for Major Neurocognitive Disorder

Poster Presenter: Sheema Imran, M.D.
Co-Authors: Asghar Hossain, M.D., Mehwish Hina

SUMMARY:

Alzheimer's disease (AD) is associated with brain insulin deficiency and insulin resistance, similar to the problems in diabetes. If insulin could be supplied to the brain in the early stages of AD, subsequent neurodegeneration might be prevented. Administering systemic insulin to elderly non-diabetics poses unacceptable risks of inadvertent hypoglycemia. However, intranasal delivery directs the insulin into the brain, avoiding systemic side-effects. Today millions people worldwide suffer from Alzheimer's or other dementia and, with the aging population, this number is expected to reach 65 million by 2030 and 115 million by 2050 (1). Few studies are currently investigating insulin and other gastrointestinal hormones and how they affect cognition. Researchers at the UW Medicine, Veteran's Administration Puget Sound and Saint Louis University have made a promising discovery that insulin applied at the level of the cribriform plate via the nasal route quickly distributed throughout the brain and reversed learning and memory deficits in an AD mouse model (2). Object recognition tests found that old mice that could not differentiate between old or new play objects, showed significant improvement in their memory after single dose of intranasal insulin. Importantly, researchers also found that intranasal insulin entered the bloodstream poorly and had no peripheral metabolic effects, a major concern in the medical community because it would lower blood sugar levels. Additionally, repeated doses increased insulin's efficacy in aiding memory. In the randomized double-blind, placebo-controlled trial led by Dr. Suzanne Craft at Brown University, the investigators studied 104 adults who had mild cognitive impairment (MCI) or were in the early to moderate stages AD (3). The trial concluded that intranasal insulin therapy improves memory and cognitive performance in people with mild cognitive impairment or early Alzheimer's disease. Intranasal insulin improves objective biomarker indices of neurodegeneration related to amyloid deposits and tau pathology in brains with early Alzheimer's disease. Therapeutic effects of intranasal insulin are detectable within a relatively short period (a few months), whereas without the treatments, neurodegeneration progresses in measurable degrees. Intranasal insulin is safe for use in elderly individuals who are in the early stages of Alzheimer type neurodegeneration. Intranasal insulin therapy holds promise for halting progression of AD.

No. 107

Identification and Mangement of Psychiatric Manifestations in Sjögren's Syndrome (PSS): A Literature Review

Poster Presenter: Sheema Imran, M.D.
Co-Authors: Asghar Hossain, M.D., Mehwish Hina

SUMMARY:

Primary Sjögren's syndrome (pSS) is a chronic autoimmune disease mainly characterized by the inflammation of exocrine glands; however, a broad spectrum of systemic manifestations may characterize the disease. This review summarizes our current understanding of the psychiatric manifestations of pSS, their pathophysiology, and treatment. The most common psychiatric manifestation in pSS is anxiety disorders with a prevalence ranging up to 57%. Other psychiatric conditions reported include adjustment disorders, schizophrenia, schizotypal, bipolar, and hypomania or mania. The pathogenesis of psychiatric-associated PSS may be linked to neuroimmunoendocrine processes, however evidence is still unclear. Due to the clinical reality of psychiatric diseases in pSS, it is imperative for psychiatrists to inquire about clinical features of SS, when examining patients with psychiatric symptoms, xerostomia, and keratoconjunctivitis sicca.

No. 108

Concussion and Mental Illness: Reversal of Psychiatric Symptoms Following Traumatic Head Injury

Poster Presenter: Sheema Imran, M.D.
Co-Authors: Avi Siwatch, Ghulam Sajjad Khan, M.B.B.S.

SUMMARY:

Behavioral changes such as poor concentration, dizziness, fatigue, headache, sleep disturbance, irritability, anxiety, and depressed mood persisting beyond 30 days is termed post-concussive syndrome (PCS) and is noted in 10-15% of patients suffering a traumatic brain injury (TBI).1 One of the first cases in literature was that of Phineas Gage, a construction worker who, after surviving a freak accident at his workplace in 1848, underwent severe personality changes. His physician at the time, noted an emotionally labile and irresponsible change in Gage's behavior after the accident.2 Here we present the case of a 60-year-old, Hispanic male with past diagnoses of major depressive disorder(MDD) for 20 years and panic disorder for 15 years. He suffered trauma to the head during an incident where he was attacked by some gang members. Following this incident, the patient reported that he no longer felt any symptoms stemming from his past psychiatric illnesses and was in a constant "happy mood". Current literature and protocol warrant immediate diagnosis and treatment of any behavioral changes following a trauma to the head, however, all imaging and neurological tests performed on our patient came back negative, in addition to an absence of any symptoms. The patient refused all treatment as he had, for all practical purposes, been "cured" of his mental problems.

No. 109

Rethinking Capacity: A Proposal for the Use of a Standardized Test for Capacity in Psychiatric Patients

Poster Presenter: Austin Takeo Momii
Co-Author: Robert G. Bota, M.D.

SUMMARY:

Contemporary biomedical ethicists construe `competence' as a minimal level of mental capacity that any patient must have in order to be considered capable of making medical decisions. When a patient is judged `competent' she/he is putatively entitled to a certain level of control over the type of treatment that she/he will receive. Control over medical decisions means that the patient will have access to salient information about her/his case and, as a consequence, medical professionals are morally required to provide her/his with detailed medical and scientific information germane to her decisions. However, in cases of incompetence, medical professionals are presumed to have permission, or perhaps even further, be morally obligated to make decisions on behalf of the patient. Moreover, it may also be permissible to paternalistically withhold information and protect the supposed incompetent patient from herself/himself. Curiously, given the preponderance of moral weight attributed to competence, very little has been offered to address and objectively verify patient competence. We therefore aim to (i) argue for the need of a screening test for medical decision making capacity and (ii) provide a sample screening test for use in hospitals that can provide assurance that the patient has capacity to make pivotal decisions regarding her/his own care.

No. 110

Delirium, Substance-Induced Mania

Poster Presenter: Brant Thayer
Co-Authors: David Roberto De Vela Nagarkatti-Gude, M.D., Ph.D., Marian Fireman, M.D.

SUMMARY:
Mr. S, a 55-year-old man with no prior psychiatric history or engagement with mental health care, was brought to the ED by police after suddenly exhibiting a violent outburst, confused mental state, and sustaining lacerations to his elbows that prompted his wife to call EMS. He had been diagnosed with pancreatic adenocarcinoma one year before which had been cleanly resected in a Whipple procedure 8 months prior. He received 11 cycles of chemotherapy (panitumumab + dexamethasone 12mg) with his last dose of chemotherapy 10 days prior to the ED evaluation. With brain MRI, urine drug screen, blood alcohol level, and serum electrolytes all within normal limits the psychiatry service was consulted to evaluate why this man with a 20-year marriage and well-known devotion to his three children suddenly appeared grandiose, pressured in speech, unable to sleep, and requiring restraint to facilitate medical evaluation in the ED. Mr. S was discharged home after 1 day evaluation but over the next month was brought to emergency departments or correctional facilities on 4 occasions despite completion of chemotherapy and lack of any new medical cause of altered mental status; each time he exhibited symptoms suggestive of mania. His behavior during this period was so disruptive that he was ordered by DHS not to contact his children and his marriage ultimately ended in separation. At follow up with oncology several months later, his mental status had returned to baseline, though he struggled with the loss of his family. In this poster, we review the difficulty in establishing a diagnosis of bipolar disorder when mania does not present until middle age and highlight the known potential risks of high dose corticosteroids while considering whether novel immunomodulatory chemotherapy could contribute to risk of major neuropsychiatric side effects.

No. 111
E-Sleuthing: Identifying Malingering Using Two Approaches to the Electronic Medical Record
Poster Presenter: Daniel C. Hart, M.D.
Co-Author: Erika M. Zavyalov, D.O.

SUMMARY:
This poster compares two cases of malingering in which the electronic medical record was scoured in order to establish patterns of onset of reported symptoms: One case, Mr. D., demonstrates a single inflexion point in which the record instantly and permanently changes. Another, Mr. C., portrays an insidious accumulation of symptoms not corresponding to any known disease process with fluctuations of physical and mental evaluations not consistent with injuries suffered. Case 1: Mr. D., a 58yo Caucasian male with reported past history of injury to shoulder while pulling survivors from a crashed helicopter, was conveyed to the emergency department after being found down in a stair case with reports anterograde and retrograde amnesia. Investigating his claims made to the many teams assigned to his care revealed that his shoulder had actually been injured in a pre-deployment training incident during which he fell while caring a litter. At the time of admission, he was already receiving two streams of disability payment and told the provider that this would help him lock in a third stream. The medical record revealed an instantaneous changing in historical reporting that changed the patient's injury from being caused by a training incident to having occurred while in a heroic role in combat. Case 2:Mr. M., a 30yo Caucasian male involved in a motor vehicle accident while on base in Iraq reported a three year history of increasing severe symptoms that started months after the initial incident and culminated in his being wheelchair bound, mild to moderately cognitively impaired, and suffering from non-epileptiform seizures. A thorough investigation revealed an insidious yet progressive appearance and augmentation of symptoms that resulted in a claim for and awarding of 100% disability pay. A chronologic assessment of records spanning both TRICARE and the VA health care systems provided much needed clarity in identifying the slow and steady increase in symptomatology. These two cases provide examples of electronic medical record usage in determining onset and course of symptoms helpful in identifying malingering.

No. 112
Evaluation of First-Onset Psychosis in Midlife: The

Importance of Organic Workup and Multidisciplinary Care
Poster Presenter: Gabriela S. Pachano, M.D.

SUMMARY:
This is the case of Mr. C, a 51 year old man with no prior psychiatric history who presented to the ER with a two month history of depressive and manic symptoms, weight loss, and recent onset of prominent paranoid delusions. Physical examination was unremarkable except for a subtle left arm weakness and left sided hyperreflexia. He was admitted to the psychiatric unit for evaluation and treatment of his psychosis. A complete organic workup was performed, as he had never experienced these symptoms before, hadn't seen a primary care provider in over thirty years, reported weight loss, and had subtle neurological findings on exam. Workup included brain MRI, electroencephalogram, chest x-ray, infectious disease workup, vitamin levels, and lead level. MRI showed a remote right frontal cortical infarct as well as punctate acute infarcts in the left parietal lobe. A subsequent CT Angiography demonstrated an occluded right Internal carotid artery (ICA), >70% stenosis of the left ICA, occluded proximal right A2 segment, diffusely diseased right cervical vertebral artery. Both Neurology and Neurosurgery were consulted and due to carotid findings, he was transferred to the Neurosurgery service and underwent a left Carotid Endarterectomy (CEA). Additionally, due to reported weight loss a CT of the chest, abdomen and pelvis was performed and results revealed an indeterminate left lower lobe peribronchovascular nodule. The patient had a significant smoking history; therefore a paraneoplastic panel was ordered which revealed a positive anti-neuronal voltage-gated potassium channel antibodies (VGKC Ab). These antibodies are associated with lung cancer and a paraneoplastic syndrome that can cause psychiatric manifestations. He will need a repeat chest CT for monitoring of this lung nodule and referral to the Neuro-Immunology clinic, given these findings. To this date, he continues to follow with Psychiatry, Neurology, Primary Care and Neurosurgery as an outpatient. This case highlights the importance of performing a complete organic workup in cases involving atypical presentations of psychosis, as well as that of performing a complete neurological exam on psychiatric patients. It also brings to light the importance of multidisciplinary care and consultation of specialists when needed. This poster will present this interesting case in more detail, as well as provide recommendations for workup for first onset psychosis in midlife. ?

No. 113
Obscure Dissociative Episodes in Complex Partial Seizures
Poster Presenter: Gregory Scott Brown, M.D.

SUMMARY:
Complex partial seizures are the most common form of epilepsy in adults. Behavioral changes, including dissociative episodes, have been discussed as a possible automatism of these seizures, especially when they originate from the temporal lobes. Complex partial seizures, diagnosed in the setting of dissociative episodes as the primary ictal event, have not been reported extensively in the English literature. Here, we report on a patient who presented to a psychiatric facility after three dissociative episodes and during her admission was found to have an abnormal EEG suggestive of bitemporal lobe epilepsy. Meticulous review of her prior medical records revealed no history of a neurological disorder or a history of seizures.

No. 114
Clozapine-Induced Myocarditis: The Need to Devise a Strategy for Early Recognition of a Potentially Fatal Adverse Reaction
Poster Presenter: Samreen Munir, M.D.

SUMMARY:
Mr.E is 31 year old male with a history of refractory schizophrenia who was admitted to our inpatient psychiatric unit with catatonia. Pt had mutism, stupor, and negativism. He was treated with lorazepam for catatonic symptoms with partial improvement, and clozapine was started for psychosis. Pt was mostly nonverbal so interval history and subjective information was difficult to obtain. After 15 days of clozapine treatment, with doses of up to 100 mg daily, he was found to have fever, diaphoresis, and tachycardia, with elevated serum CRP and troponin and eosinophilia developing

a few days later. Transthoracic echocardiogram demonstrated a mild pericardial infusion. Other possibilities of pericardial effusion were taken into account, but clozapine seemed the most likely explanation. Symptoms and signs abated within 2-3 days of discontinuing clozapine, except the pericardial effusion, which resolved over the following month. The patient was monitored closely without any further recurrence of myocarditis. Although clozapine is known to cause myocarditis and cardiomyopathy, it can be easily missed given the nonspecific presentation. Our patient was mute and unable to report symptoms. Myocarditis is an uncommon, potentially life-threatening disease that presents with a wide range of symptoms and can cause significant morbidity and mortality. Literature search revealed that clozapine-induced myocarditis may be underdiagnosed in the United States as compared to countries like Australia where the incidence is >1% , as compared to <0.1% worldwide. In this poster, we will discuss the need for cardiac monitoring guidelines such as the Clozapine REMS program to minimize the risks and mitigate the effects of clozapine-induced myocarditis, especially in the first 4 weeks of starting Clozapine, as the incidence is the highest in this period. Routinely adding markers of inflammation (e.g. CRP or ESR) and markers of cardiac damage (troponin or CPK) to the already mandated weekly routine blood work may facilitate earlier detection of clozapine-induced myocarditis. As myocarditis can be life threatening, close monitoring by taking pragmatic measures will increase case ascertainment and make physicians more cognizant of this rare but dangerous side effect.

No. 115

The Devil Is in the Details: Formication as a Dose Related Side Effect of Antidepressant Medication

Poster Presenter: Shambhavi Chandraiah, M.D.

SUMMARY:

Abstract Ms. H, a 61 year old Caucasian female with a 15 year history of depression presented to the psychiatry outpatient clinic for treatment of depression with insomnia. She had had 2 prior trials of Selective serotonin reuptake inhibitors with tachyphylaxis as well as irritability with a norepinephrine dopamine reuptake inhibitor. At presentation she had been on Venlafaxine 150mg for 11 years with diminishing effect in the past 2 years. Concurrent medical problems included arthritis and chronic lumbosacral pain treated with Tramadol and Meloxicam. Her Venlafaxine dose was increased to address the depression with addition of Trazodone 50mg mg at night for insomnia. At 3 week follow up the patient reported improved insomnia and sleep quality but also morning sedation from trazodone. As well, she reported new onset of evening and nighttime sensations (not present in the morning) of feeling like bugs crawling over her skin (formication) after starting Trazodone. The patient had chosen to discontinue trazodone herself with resolution of this side effect. We then embarked on a detailed assessment to rule out other potential etiologies for the formication including exposure to new topical or over the counter agents, herbal products, and drugs of abuse. She reported no past history of formication with prior antidepressant or other medication use. The dosage of her other medications for pain had remained the same for many months. She denied past psychotic symptoms or other current hallucinations. We chose to re-challenge the patient with Trazodone at a lower dose of 12.5-25mg (to minimize the morning sedation) with no return of formication. In this poster we discuss the various other reported causes of formication including those that can more predictably cause this symptom (cocaine or stimulant abuse), as well as various antidepressants, parkinsonian agents, drug interactions that may increase levels of a potentially offending agent, as well as dose related occurrence of formication. Hypotheses regarding the role of serotonin, norepinephrine, and dopamine in formication will be addressed. The importance of carefully ruling out other causes while confirming the temporal relationship to the offending agent in the onset or offset of formication will be discussed. This approach also applies to the careful delineation of any new unusual side effect with any medication use. Strategies to address such medication side effects include dose change, re-challenge with the medication, changing or stopping medication.

No. 116

The Use of Quantitative EEG for Differentiating Frontotemporal Dementia From Late-Onset Bipolar Disorder

Poster Presenter: Sinem Zeynep Metin
Co-Authors: Turker Erguzel, Gulhan Ertan Akan, Celal Salçini, Merve Çebi, Betül Koçarslan, Baris Metin, Oguz Tanridag, Nevzat Tarhan

SUMMARY:
The behavioral variant Frontotemporal dementia (bvFTD) usually emerges with behavioral changes similar to changes in late life bipolar disorder (BD) especially in the early stages. According to the literature, a substantial amount of bvFTD cases has been misdiagnosed as BD. Since the literature lacks studies comparing differential diagnosis ability of electrophysiological and neuroimaging findings in BD and bvFTD; we aimed to show their classification power using an artificial neural network and genetic algorithm based approach. Eightteen patients with the diagnosis of bvFTD and 20 patients with the diagnosis of late-life BD are included in the study. All patients' clinical MRI scan and electroencephalography recordings were assessed by a double blind method to make diagnosis from MRI data. Classification of bvFTD and BD from total 38 participants was performed using feature selection and a neural network based on general algorithm (GA). The artifical neural network method classified BD from bvFTD with 76% overall accuracy only by using on EEG power values. The radiological diagnosis classified BD from bvFTD with 79 % overall accuracy. When the radiological diagnosis was added to the EEG analysis, the total classification performance raised to % 87 overall accuracy. These results suggest that EEG and MRI combination has more powerful classification ability as compared to EEG and MRI alone. The findings may support the utility of neurophysiological and structural neuroimaging assessments for discriminating the two pathologies.

No. 117
Consideration of Auditory Hallucinations in Deaf Patients With Psychiatric Disorders: A Case Report
Poster Presenter: Stephanie Marie Klassen, M.D.

SUMMARY:
Mr. B, a 45-year-old deaf, non-speaking, Hispanic male with an unclear past psychiatric history of intellectual developmental disorder (IDD), presents to the inpatient psychiatric facility due to aggressive behavior and increasing agitation. Per family, patient destroyed property at the home, would leave the house at odd hours, and was difficult to control. He was not on any medications at the time. In the hospital, patient was aggressive towards staff, not redirectable, and destroyed property in the doctor's office. His behavior was eventually controlled on antipsychotic medication and soon he was calm and cooperative with staff and was able to follow simple instructions in sign language. Due to his IDD and little education (he was illiterate and non-fluent in sign language), communicating with the patient was very difficult, and assessing all parts of the mental status exam was problematic. Each interview was completed with an American Sign Language (ALS) interpreter, but it was unclear if patient understood each question. When asked about psychotic, depressive, or manic symptoms, the patient would immediately deny, or would just shrug his shoulders; at times he even used signs that did not make interpretable sense to the interpreter. He was also difficult to engage and had poor eye contact with the staff and interpreter, which further impeded a full interview. It was unclear if Mr. B was internally preoccupied, and the team began to question the possibility of auditory hallucinations in a deaf patient. In this poster, we discuss the challenges in diagnosing psychosis and the differences in auditory hallucinations in a deaf patient with a psychiatric disorder.

No. 118
Challenges in Diagnosis and Management of a Patient With Clozapine-Induced Delirium
Poster Presenter: Alexander Munjal, M.D., M.P.H.

SUMMARY:
Ms. M., a 63-year-old female with a past psychiatric history of schizoaffective disorder (bipolar type), panic disorder, and histrionic personality disorder, presented to the psychiatric consult service with altered mental status, disorganized thought process, bizarre speech with frequent reference to numbers, decreased verbal interaction, and response to internal stimuli. She was subsequently admitted to the inpatient psychiatry unit under a Temporary Detention Order due to risk related to inability to care for herself. The patient had been dropped off by her husband at her daughter's house 2 days prior.

Her daughter presented with her, but had not seen the patient for about a year due to the patient and her husband relocating out of state for his work. She reported that her husband had left her there due to frustration with her symptoms. Although it was unclear, she believed symptoms had been present for 6 months or longer. Clinic notes from 5 years prior to presentation confirmed a history of schizoaffective disorder, and outside records confirmed clozapine dosing. Initial laboratory workup was significant for cocaine on urine toxicology, but there were no other signs of acute cocaine intoxication such as vital abnormalities or EKG changes. Her level of activity was hypoactive. Clozapine levels were drawn but not immediately available to guide management. The differential diagnosis included depressive episode with decompensation of schizoaffective disorder in the setting of suspected medication noncompliance, toxic metabolic encephalopathy, and medication toxicity. The patient's condition initially worsened, and the team developed concern for catatonia due to increased hypoactivity, grimacing, awkward posturing, and verbigeration. However, lack of improvement despite treatment prompted revisiting the diagnosis. Workup including routine EEG revealed the presence of toxic-metabolic encephalopathy. She demonstrated subsequent improvement after discontinuation of clozapine. In this poster, we discuss factors confounding diagnosis and management of this patient with medication-induced delirium in the setting of a documented and long-standing history of primary thought disorder.

No. 119

Increased Risk of Readmission for Depression or Bipolar Disorder Following an Admission for Epilepsy Compared to Stroke and Medical Admissions

Poster Presenter: Anna Kim, M.D.
Co-Authors: Kyle Rossi, Nathalie Jette, Ji Yeoun Yoo, Kenneth Hung, M.D., Mandip Dhamoon

SUMMARY:
OBJECTIVE: To determine if epilepsy admissions, compared to admissions for other medical causes, are associated with a higher readmission risk for mood disorders. METHODS: The Nationwide Readmissions Database is a nationally representative dataset comprising 49% of US hospitalizations in 2013. In this retrospective cohort study, we used ICD-9-CM codes to identify medical conditions. Index admissions for epilepsy (n = 58,278) were compared against index admissions for stroke (n=215,821) and common medical causes (n=973,078). Readmission rates (per 100,000 index admissions) for depression or bipolar disorders within 90 days from discharge for index hospitalization were calculated. Cox regression was used to test for associations between admission type (defined in 3 categories as above) and readmission for depression or bipolar disorder up to 1 year after index admission, in univariate models and adjusted for age, sex, psychiatric history, drug abuse, income quartile of patient's zip code, and index hospitalization characteristics. RESULTS: The adjusted hazard ratio (HR) for readmission for depression in the epilepsy group was elevated at 2.80 compared to the stroke group (95% confidence interval (CI) 2.39-3.27, p<2×10-16), and 2.09 compared to the medical group (95% CI 1.88-2.32, p<2×10-16). The adjusted HR for readmission for bipolar disorder in the epilepsy group was elevated at 5.84 compared to the stroke group (95% CI 4.56-7.48, p<2×10-16), and 2.46 compared to the medical group (95% CI 2.16-2.81, p<2×10-16). CONCLUSION: Admission for epilepsy was independently associated with subsequent hospital readmission for mood disorders. The magnitude of elevated risk in this population suggests that patients admitted with epilepsy may warrant targeted psychiatric screening during their hospital admission.

No. 120

Oculogyric Crisis From Administration of IV Metoclopramide and IV Haloperidol Followed by Feigned Symptoms for Primary Versus Secondary Gain

Poster Presenter: Anna Kim, M.D.
Co-Authors: Kyle Rossi, Michelle Fabian, Justin Patrick Meyer, M.D., Kenneth Hung, M.D.

SUMMARY:
Background: Oculogyric crisis and other acute dystonic reactions are severe paroxysmal adverse effects of many anti-psychotics and anti-emetics. Alternatively, functional or feigned (for primary or secondary gain) movement disorders are common and not necessarily a diagnosis of exclusion when

seen by an experienced physician. In this case, our patient experienced one episode consistent with an oculogyric crisis followed by a second episode that was felt to be feigned for secondary gain. Case Report: A 48-year-old woman with no known psychiatry history and a history of migraine presented to the emergency department with headache for five days, mild fever, nausea, and vomiting. Per her chronic pain doctor, she was prescribed fioricet, zolpidem and alprazolam, and there was concern for medication misuse. Vitals were normal. Physical exam was unremarkable. Labs showed WBC of 14. Serum toxicology was unremarkable and urine toxicology was positive for opiates and barbituates. Overnight, she was given metoclopromide 10 mg IV twice and haloperidol 5 mg IV twice. She also received morphine, ketorolac, and ondansetron. She briefly felt better after haloperidol but reported to staff thoughts of killing herself. Psychiatry was consulted for suicidality. She was admitted to medicine and found in the morning to be stiff and poorly responsive. Neurology and psychiatry were called due to concern for possible neuroleptic malignant syndrome. CPK was 157. Blood pressure was elevated to systolic 180s, otherwise vitals were normal. On exam, patient presented with eyes wide-open, upward deviated gaze, mouth open in an "O" shape, neck and both arms stiff and extended in fixed posture. She was unable to respond verbally. She was diagnosed by neurology and psychiatry with oculogyric crisis and acute dystonia. Symptoms resolved within 5 minutes of giving IV lorazepam and IV diphenhydramine. Later in the evening, these symptoms recurred, though were less consistent and pronounced. The patient was able to speak through the abnormal movements, stating repeatedly "I need a pain pill." Abnormal movements transiently resolved when examiners left the room, and she was observed by a sitter. While patient was having this oculogyric crisis-like episode, a fly opportunely landed on her face, which caused her to stop the movements to swat at it before resuming the posturing. She received more diphenhydramine, followed by benztropine. The following morning she was back to baseline. Conclusion: It is important for physicians to exercise caution when administering multiple medications with dopamine blockade, notably IV haldol and metoclopromide. It is also important for the medical team to keep an open mind and remain vigilant when the clinical picture suggests potential functional embellishment or a feigned abnormal movement for primary (factitious) or secondary (malingering) gain. Of note, the second event possibly could have stemmed from the organic, first event.

No. 121

Predicting Successful Discharge From a Psychiatric Observation Unit: Which Factors Matter?

Poster Presenter: Amit A. Parikh, M.D.
Co-Authors: Natalie Anne Lester, M.D., Sandy Brundage

SUMMARY:

Predicting Successful Discharge From a Psychiatric Observation Unit: Which Factors Matter? Co-authors Amit Parikh, M.D., Sandy Brundage, Laura Thompson, M.D., M.S., Natalie Lester, M.D. Abstract Background: The number of psychiatric patients presenting to Emergency Departments (ED) across the country has risen during the past 10 years. At The Ohio State University (OSU), the number of ED patients seen annually by the Psychiatric Emergency Services (PES) increased from 3500 to 7500 from the years 2012 to 2016. As the number of patients seeking care in ED's has increased, the number of inpatient psychiatric beds has stayed the same; the gap between supply and demand has continued to increase. While observation units in the medical setting have been well established as both cost-saving and efficient, this model has not been widely explored in a psychiatric setting . At OSU we have been using a Psychiatric Observation Unit, called the Crisis Assessment Management and Linkage unit (CALM), to bring this model of care to patients in acute psychiatric crisis. Due to the relative lack of these units across the country there is a dearth of data regarding demographics and clinical factors of patients who can be successfully managed in this practice environment. The aim of this study is to identify characteristics of patients admitted to the CALM unit that predict successful management in an observation setting. Methods: Patient-level data from the electronic medical record (EMR) was gathered from 1000 randomly selected individuals who were admitted to the CALM unit from 2014-2016. The data include age, gender, race, ethnicity,

marital status, financial class, referral source, arrival means, and type of insurance. Observation care was deemed a success when the patient was discharged to home and did not require inpatient psychiatric care. Data were analyzed using Pearson's chi-squared tests. Results: Young adult patients (ages 18-44) were more likely to be successfully discharged from CALM than either older or younger patients (Chi2(6)=13.7, p=0.034). Insurance type was also a significant predictor, with 70.6% of patients on a managed care insurance plan vs 57.32% of patients of a Medicare plan discharged (Chi2(4)=906, p=0.047). Patients who presented to the ED as self-referrals (71.4%) or by law enforcement (68.8%) were more likely to be successfully discharged than patients who were referred by other health care providers (48.6%) (Chi2(2)=8.5, p=0.014). Conclusion: Understanding factors that predict which patients can successfully be managed on a psychiatric observation unit can provide practitioners with valuable information when making the level-of-care decisions for ED patients in acute psychiatric crisis. Development of psychiatric observation levels of care may reduce the use of mental health care dollars and stabilize patients in the least restrictive treatment setting.

No. 122

Complexities in Clinician Decision Making in a Case of Suspected Malingering

Poster Presenter: Catalina Trevino Saenz, M.D.
Co-Authors: Sina Shah, M.D., Raj V. Addepalli, M.D.

SUMMARY:

This is a case of a 42 year old Hispanic male with past psychiatric history of self-reported depressed mood and chronic suicidal ideation with multiple inpatient psychiatric admissions due to similar complaints. The patient presented to the Psychiatric Emergency Service complaining of command auditory hallucinations to kill himself. After evaluation patient was found psychiatrically cleared for discharge. Upon learning about his imminent discharge from the Emergency room, patient reported conditional suicidal ideation and made a hanging from neck gesture with a bedsheet. Patient was deemed for admission. The patient reported history of daily cocaine use, history of incarceration for 16 years and of non-adherence to home psychiatric medication which included an antipsychotic. Upon admission to the inpatient unit the patient was restarted on home medications. Marked discrepancy was found between the patient's claimed symptoms and the treatment team's observations. Presenting symptoms resolved within hours of initial evaluation. Once resolution of symptoms was sustained for three consecutive days and medication compliance was maintained, patient again expressed conditional suicidal ideation in the context of his imminent discharge from the inpatient unit. Review of medical records indicated that he was last discharged from the inpatient psychiatric unit 8 days prior to current admission with a similar presentation. Patient had a multiple psychiatric inpatient admissions with nearly identical presentations documented. Contact with his assisted outpatient treatment providers indicated that the treatment team repeatedly experienced difficulty addressing the veracity of his suicidal threats which lead to repeated referrals to the Emergency room. Decision was made to further patient's evaluation with a symptom validity test. Subsequent testing with the MMPI-2 inventory and M-FAST (Miller Forensic Assessment Test) revealed a profile highly suggestive of Malingering per DSM 5 (Z76.5). The patient presented extreme symptoms, a rare combination of symptoms, unusual hallucinations, unusual symptom course, and suggestibility to unusual items.

No. 123

Mood and Meningioma: Considering Neuroimaging in the Emergency Psychiatric Setting

Poster Presenter: Christopher Chin
Co-Author: Vilayannur Rao

SUMMARY:

In this poster, we present a case illustrating the consideration of neuroimaging in an atypical psychiatric presentation. Additionally, we briefly review findings from the literature that warrant such work-up. Ms. K is a 59-year-old Guyanese female with no past psychiatric history who presented to psychiatric emergency services for evaluation of sleep disturbance and personality changes. The patient was flown to the US and brought in by her family because she was not sleeping and having emotional instability for the past month. For the past two weeks, she exhibited mood lability and

delusional behavior. Her family also reported disinhibited and bizarre behavior like talking to the TV. Despite denying these reports, she endorsed recently speaking with her deceased mother, yet had an indifferent and apathetic affect. Upon further questioning, she also revealed a recent episode of confusion. Neurological exam was unremarkable with no focal deficits. CT scan of the head was obtained which demonstrated a large extra-axial hyperdense lesion in the right frontal region with 4 mm midline shift to the left. The patient was immediately transferred to medical emergency department for neurosurgical evaluation yielding a diagnosis of meningioma. Her neuropsychiatric symptoms resolved after craniotomy and resection of the meningioma. Although rare, psychiatric symptoms may be the only presenting signs heralding a brain tumor, especially in the emergency setting. Thorough history, physical exam, and collateral information are paramount in developing an index of suspicion for organic pathology, which can expedite the diagnosis. New-onset atypical psychiatric symptoms and personality changes in patients over the age of 40 years should suggest neuroimaging, even in the absence of focal neurologic signs. Symptoms of confusion, recent memory loss, anorexia without body dysmorphic symptoms, and relative lack of insight may also allude to organic brain disease.

No. 124

Diagnosing Compartment Syndrome Related to Opioid Overdose in a Psychiatric Crisis Setting

Poster Presenter: Esi Bentsi-Barnes, M.D.
Co-Author: James Jefferson Graham, D.O.

SUMMARY:

Mr. K, a 26 year-old Caucasian male with a past psychiatric history that included opioid use disorder presented to the Crisis Reponses Center (CRC) requesting detoxification from heroin and benzodiazepines. Of note, Mr. K was triaged by an RN working in a medical emergency room just prior to presentation to the CRC. Upon initial presentation, patient was observed to have pronounced swelling in both upper extremities, as well as his lower right extremity. Mr. K denied any pain at that time, but did acknowledge reduced range of motion and inability to bear weight on his right lower extremity. During further assessment, patient admitted to overdosing on intravenous heroin two days prior and that this caused his body weight to lie on his right leg for an extended period of time. Patient reported going to another medical emergency department for evaluation prior to presenting to the ED mentioned previously, but was discharged. While Mr. K was in the CRC, labs were drawn in order to rule out any medical emergencies. Labs returned with a Creatine Kinase (CK) value of 56, 305U/L (ref range 52-336 U/L). The patient was transferred to the medical emergency department and from there was admitted to the medical hospital with a diagnosis of compartment syndrome. Prior to discharge, Mr. K required a fasciotomy of the right lower extremity due to the risk of necrosis. This case highlights the importance of recognizing the less common, though dangerous, complications of long-term immobility during opioid use. In addition, it highlights the need to maintain vigilance for medical emergencies while working in a psychiatric setting.

No. 125

The Neurobiology of Suicide in Obesity

Poster Presenter: Lala Park, M.D.
Co-Author: Fernando Espi Forcen, M.D., Ph.D.

SUMMARY:

Background: Obesity has been related to inflammation and depression. In this talk we will present a general review of biomarkers in suicide and medical illness and from our obesity study in the emergency room. Method: We present preliminary results from a study of adult subjects presenting to a general hospital emergency room for depression. We measured the body mass index (BMI), white blood cells, lymphocytes, neutrophils, eosinophils, monocytes. Participants completed a 7-item Hamilton Depression Rating Scale. Correlation between BMI and neuroinflammatory markers to total 7-item HDRS scores and its individual items including suicidality scores were calculated. Results: Data was available from N = 76 subjects after applying exclusion criteria of acute intoxication, withdrawal, and malingering. Increased BMI was associated with increased anhedonia in males ($p = 0.03$) and increased somatic anxiety in females at a trend level but not to suicidal ideation for the group as a whole or in each of the genders. Depressed

mood was associated with increased total WBC count (p = 0.008) and increased monocyte count (p = 0.05). Increased suicidality correlated with increased basophil count (p = 0.02). Conclusions: Preliminary results of this study suggest that increased BMI is associated with depressive symptoms though the effect on the type of depressive symptoms may be different in males and females. The relationship of basophils and increased suicidality in emergency setting needs to be examined in future large scale studies as basophils secrete a number of cytokines involved in the inflammatory response.

No. 126

NMS or Not NMS, That Is the Question...

Poster Presenter: Oner Gurkan Gonen, M.D.

SUMMARY:

The Neuroleptic Malignant Syndrome (NMS) is a medical emergency which is less frequently associated with atypical antipsychotics such as clozapine when compared with classic or "typical" antipsychotic medications. NMS presents with a several clinical features, including tachycardia, mental status changes, diaphoresis, fever, rigidity, and elevated creatine phosphokinase (CPK). However, case reports have also described atypical NMS presentations, including lack of rigidity with clozapine. NMS symptoms can also be associated with clozapine overdose, which can further confound an initial presentation in an emergency department (ED) setting. We present the case of a 21 year-old man with a diagnosis of Schizophrenia treated with clozapine who initially presented to ED for disorganized behavior, confusion, increased CPK levels, sialorrhea, and autonomic instability. Initially suspected to be secondary to NMS in the context of a recent rapid titration of his medication, it was later determined that the patient had been non-compliant with treatment and overdosed on clozapine in the hours preceding admission. The review of this case will help to highlight atypical presentations of NMS with clozapine, symptoms associated with clozapine overdose, and ways to differentiate each presentation when adequate history is unavailable.

No. 127

First Contact in ED as Evidence of Poor Access to Ambulatory Mental Health Care in a Universal Health Care System

Poster Presenter: Paul Kurdyak

SUMMARY:

Introduction: Some mental health-related ED visits may be avoidable if individuals have access to effective ambulatory care. The study objective was to describe individuals whose mental health ED contact was their "first contact" with mental health services, and factors associated with this potential indicator of suboptimal access to care. Methods: From a population-based cohort Ontario, Canada residents 16 years of age and older with an incident mental health-related ED visit between 2010 and 2014 (n=435,875), we compared patients with and without outpatient mental health physician visits in the prior 2 years (first contact) on demographic, clinical and health service use variables. We also evaluated a subset (N=37,767) with an suicide-related ED visit. We used multivariable models to identify factors independently associated with first contact. Results: The incident ED visit was the first contact for 47% of patients Overall (N=206,419), and 47% for those with a suicide attempt (N=17,701). The factors independently associated with first contact were similar for the total population and for the suicide attempt ED visits. There was an increased likelihood of first contact for those who were: in the youngest or oldest age category, male, immigrant, rural, and having a substance use disorder. Increasing number of comorbid conditions, having a usual care provider, and presenting to the ED with high acuity were associated with a decreased likelihood of first contact. Discussion: First contact is common among mental health ED patients, including those presenting with a suicide attempt. The factors associated with first contact ED visits are known to be associated with poor access in general. Therefore, measuring first contact mental health ED visits may be a useful way to evaluate population-based access to mental health care.

No. 128

The Psychiatric Emergency Service in the Netherlands

Poster Presenter: Stefan Streitz

SUMMARY:

The psychiatric emergency service in the Netherlands Every region in The Netherlands has got an emergency service. This is a team of people that immediately goes to see the psychiatric patient after an instruction of for instance the general practitioner or the police. This special team works 24 hours a day, 7 days a week. The patient is then visited by members of the team, a social worker accompanied by a psychiatrist, or the patient will go to the ambulant unit (the polyclinic) directly. This is a very effective procedure, because behind the two people that visit the psychiatric patient, is a whole team of people who have the opportunity to start an ambulant treatment the day after. Through this team we have the opportunity to treat patients intensively without a needed admission in the clinic. The basis of this team are social-nurse-therapists who are very skilled. These people take lead in the treatment and have a psychiatrist as a back-up. Suicidal patients are through a special procedure included in a clinic upon a juridical decision. If it is expected that the patient is dangerous, the police will accompany the emergency teams. If psychiatric medication is needed, the treatment will start directly. Other forms of treatment are psychotherapy, a short treatment by conducting 5 meetings with the patient, or intensive ambulant treatment. In my opinion it is a very good example of how ambulant treatment of psychiatric patients works and is effective for everybody involved.

No. 129

Assessment and Management of Aggression and Violence: A Literature Review

Poster Presenter: Sandhya Chinala

SUMMARY:

Background: Violent incidents in the psychiatric setting, especially in the emergency and inpatient unit is a frequent and serious problem. Aggression and violence are accompanied by negative psychological and physiological consequences for both staff and the patients. Patient violence and aggression is prevalent in clinical care settings, yet clinicians are often inadequately trained to assess and respond to these types of behaviors. In this literature review, we identified key strategies and timely interventions in the management of aggressive patients in the emergency and inpatient settings. Methods: The authors review the literature and provide information. Results were reviewed from the past 15 years. We conducted a systematic search of electronic database for review articles or studies examining patient violence and aggression in critical care setting. Results: Risk factors and imminent signs of violent patient behavior are presented. We conclude with recommendations for pharmacological and psychological interventions that can help manage aggressive behavior in the emergency and inpatient settings. Conclusion: The relatively high frequency of aggressive and violent behavior in critical care settings increases the likelihood that clinicians working in this environment will encounter this situation. With the adequate information trainees will feel confident in their training and skills when dealing with aggressive and violent patients.

No. 130

Prevention of Mental Disorders in Children and Adolescents and Promotion of Mental Health: A Literature Review

Poster Presenter: Sandhya Chinala

SUMMARY:

Mental Disorders can occur throughout the life span, but the type and nature of the illnesses vary with the age. In the United States, at least 12 percent of the nation's 74 million children and adolescents suffer from one or more mental health disorders-including autism, attention deficit hyperactivity disorder, severe conduct disorder, depression, alcohol and psychoactive substance abuse and dependence. Instead of investing in prevention and early intervention programs and providing access to appropriate services, we have unconscionable rates of suicide, school dropout, homelessness and involvement in the juvenile justice system. Children are a supremely important asset. Their nurture and solitude are our responsibility. In order to achieve desired outcomes one should embrace all those services that contribute to the mental health care of children and adolescents, whether provided by health, education, social services or other agencies. Prevention of mental disorders is a public health priority. In view of the high and increasing burden of mental and behavioral disorders and the recognized limitations in their treatment, the only sustainable

method for reducing their burden is prevention. Evidence from home visiting interventions during pregnancy and early infancy, addressing factors such as maternal smoking, poor social support, parental skills and early child-parent interactions, have shown health, social and economic outcomes of great public health significance. In this literature review, we explore some of the evidence based interventions that can prevent mental disorders and help in promoting mental health.

No. 131

Cardiovascular Risk Assessment of ADHD Medications: A Literature Review

Poster Presenter: Navdeep Grewal

SUMMARY:

Pharmacotherapy has proven to be cost effective compared with no treatment or behavior therapy alone among children, adolescents and adults with ADHD.Both stimulants and non-stimulants pharma therapy have well established efficacy and safety profile. However side effects especially cardiovascular pose a big factor for medication compliance and adherence in the affected patient population. Sudden deaths and cardiac arrhythmias are the severe complications from pharmacological treatment of ADHD.Even these are rare events but is of significant concern for patients, caregivers and health care providers. As the FDA approved pharmaceuticals for ADHD carries a black box warning, this creates a scare for not seeking treatment. Undiagnosed and untreated ADHD ads on to the economic burden of job loss due to behavior difficulties, coping with daily stress of life as the symptoms get worse for these patients under stress. Patients are often found to self-treat in such scenarios with alcohol and other drug seeking behaviors. And in these patients things escalate to other morbid psychiatric disorders like Major Depression and even suicide. So there is a need to investigate the literature with evidence about severe cardiovascular risks associated with ADHD medications. Methods: The objective of this study was to conduct a literature review of the evidence of an association between prescription ADHD medications (stimulants and non-stimulants) and severe cardiovascular events. PUBMED, MEDLINE and Google Scholar searches were made with key words like ADHD cardiovascular risks, CNS Stimulant side effects, and Atomoxetine side effects. More than 50 studies were encountered. Out of these ten studies were selected to be included for the review. Selected studies were case based cohort or systematic review studies of population of children adolescents or adults using prescription medicine as the independent variable and cardiovascular events like Changes in BP, HR, arrhythmia, prolonged QT or stroke or sudden deaths as the dependent variable. Results: All studies included report no association of adverse cardiovascular events like sudden death with prescription medicine use. The only reported side effects associated with stimulant medication of amphetamine class are increases in systolic and diastolic blood pressure and heart rate in children, adolescents and adults. Orthostatic hypotension and marked bradycardia has been reported with alpha 2 adrenergic receptor agonists like guanfecine and clonidine either as monotherapy or add on to psychostimulants. Risk of overdose exists with any ADHD medications and especially with other coexisting Psychiatric disorders like Bipolar Depression. Conclusion: New data coming clearly suggest that sudden death or stroke risks associated with stimulant and non-stimulant use is individual patient based not to all population treated with the same medications.

No. 132

Are Psychosocial Interventions Effective in Preventing Relapse in Alcohol Use Disorder?

Poster Presenter: Navdeep Grewal

SUMMARY:

Introduction: Alcohol use disorder is a major contributor of financial burden in today's health care costs especially in chronic liver disease. CDC reports 50% mortality from chronic liver Disease in US is attributable to excessive alcohol use. Although Disulfiram, naltrexone and acamprosate have been found to be effective in managing AUD.There is substantial evidence that demonstrates the value of psychosocial interventions in treating AUD. Mental Disorders like Major Depression and anxiety often coexist in AUD patients. These dual diagnosis impact negatively on the course of illness and treatment outcomes. Common approaches for the treatment of alcohol dependence include individual or group

psychotherapy, one of the four FDA approved medications, Alcohol Anonymous or other mutual help organizations or some combination of these approaches. Despite major advances in research and development of effective psychotherapies and medications, many individuals who receive empirically supported treatment for alcohol dependence do not experience sustained reductions in drinking and associated problems. This research paper is an effort to review literature about clinical studies done to improve the effective treatment and relapse prevention in Alcohol use disorder. Methods: Relevant search for finding studies in search engines like PubMed, Ovid and psychiatry online was initiated. More than one hundred hits were obtained when key words like psychosocial interventions, relapse prevention and Alcohol use Disorder or Alcoholism were used. After a thorough screening of these results, five randomly controlled trials studies were selected and discussed to answer the specific question in the current study. Results and Conclusion of Current Question of Relapse Prevention in AUD: The challenging task under hand in chemical dependency units treating patients is to maximize the benefits for the relapsing patients with Alcohol use disorder. After the current research, it is fair to say that psychosocial interventions are effective under certain patterns of drinking status like in patients that carry a dual diagnosis of chronic liver disease and Alcohol related injuries as the evidence from studies suggest. The rest of the population of relapsers, the most powerful study conclusions come from USPSTF WHO study. This study recommends that clinicians screen adults aged 18 years or older for alcohol misuse and provide persons engaged in risky or hazardous drinking with brief behavioral counseling interventions to reduce alcohol misuse. Based on the classification of relapse determinants and high risk situations proposed in these models, numerous treatment components have been developed that are aimed at helping the recovering alcoholic cope with high risk situations. Definitely, these strategies help in relapse prevention in certain populations of high risk drinking. Brief Interventions in outpatient settings have shown some evidence of e

Recurring Severe Hypothermia and Refractory Mania in the Setting of Atypical Antipsychotic, Valproic Acid and Oxcarbazepine Therapy

Poster Presenter: Oluwadamilare Ajayi

SUMMARY:

Ms. A. is a 76-year-old Caucasian female with a life long history of bipolar disorder type 1, with primarily manic episodes characterised by aggressive hypersexual behaviours, grandiose and paranoid delusions. She is a patient on a chronic geriatric psychiatry unit. After years on various atypical antipsychotics and valproic acid, she suddenly developed recurring severe episodes of hypothermia. This included treatment with quetiapine, olanzapine, valproic acid and oxcarbazepine therapy, occasionally complicated by urinary tract infections. Rectal temperatures ranged from 90°F to 95.2°F during a total of six true hypothermic episodes. Thorough medical work-up revealed no other apparent cause other than her psychiatric medications and they were ultimately discontinued. Unable to tolerate typical medications for bipolar disorder, she was successfully treated with a novel regimen without inducing hypothermia, including tamoxifen, a protein kinase inhibitor. In this poster, we review the literature of hypothermia in association with various psychiatric medications, and explore other factors that may have played a role in the development of her hypothermia. Finally, novel treatment regimens are reviewed for possible use in such patients.

No. 134

Neonatal Abstinence Syndrome and Neurobehavioral Outcomes: Case Series Report of Children at an Appalachian Psychiatric Clinic

Poster Presenter: Oluwadamilare Ajayi

SUMMARY:

Background: The opioid epidemic has been declared a national emergency. This epidemic has infiltrated all socioeconomic strata, the fastest growing demographic being that among rural Caucasian women. This indicates that it is ripping apart the fabric of society in far flung towns with little access to specialised addiction treatments. One aspect of the opiate addiction epidemic is the use in pregnant women. Babies with prenatal exposure to opiates, whether it is heroin or suboxone, are at risk for

Neonatal Abstinence syndrome at birth. While this syndrome can be managed medically in the NICU, the long-term effects of prenatal opiate exposure is not well-defined. In WV, 1 in 5 pregnancies are reported to have prenatal substance exposure. Methods: In this case series, we selected cases that presented to the University Child and Adolescent Psychiatric Clinic for psychiatric evaluations and had either a diagnosis of Neonatal Abstinence Syndrome at birth or were described to have symptoms similar to NAS as observed by the caregiver. We completed a chart review, including birth history when available, their medical history, their psychiatric symptoms, evaluations for possible prenatal alcohol exposure effects, psychological evaluations and treatment to date. Findings: While most children presented to treatment for common complaints such as inattention or hyperactivity, they also had concerns for mood swings. Many of the children were exposed to a variety of traumatic situations-such as placement in foster care and other adverse experiences that could be an outcome of substance abuse in parents. Children often needed a pharmacological regimen beyond that of routine ADHD treatment such as stimulants. Our cases also were primarily receiving healthcare benefits through Medicaid. Conclusions: School-age children in our sample presented with problems related to hyperactivity, impulsivity, inattention, speech and language issues and some social skills deficits. This suggests that effects of prenatal opiate exposure can persist into school-age. Further studies are needed to define the long-term outcomes. Clinicians must be aware of the possibility of such exposure when evaluating children. Psychiatrists treating adults with addiction must be mindful of the role of patients as parents. To reduce the incidence of Neonatal Abstinence Syndrome, psychiatrist must regularly inquire all men and women of child-bearing age about their current substance use patterns and plans for pregnancy. If pregnancy is not intended, then they must be guided towards appropriate contraception during recovery. If pregnancy is intended, then information on the possible effects of substances on the baby and resources on abstinence and recovery must be shared.

No. 135

Treatment of Childhood-Onset Schizophrenia: A Case Report

Poster Presenter: Tahira Akbar, M.D.
Co-Authors: Naveed Butt, Asghar Hossain, M.D.

SUMMARY:

Introduction: Early-onset schizophrenia (EOS) is defined as schizophrenia with onset prior to 18 years of age. Schizophrenia with onset between ages 13 and 18 is also referred to as adolescent onset. Onset of schizophrenia prior to age 13 is referred to as very early onset or childhood onset schizophrenia. Childhood-onset schizophrenia (COS), characterized by onset before age 13 years, has a prevalence of approximately 1 in 40,000 (1) Case Report: We presented a challenging case of 8-year-old female who was sent from school to Bergen Regional Medical Center for psychiatric evaluation, secondary to suicidal ideation and command type hallucinations of demonic voices to kill herself. Patient had two previous suicide attempts and reported alleged sexual abuse by her uncle at age 6-8 years. No history of substance abuse and no history of psychiatric illness. She was admitted and started on: - Risperidone 0.25 mg p.o q.h. s She responded well with improvement of her positive symptoms with a plan to follow up with outpatient psychiatrist. Discussion: Misdiagnosis of primary psychotic disorders such as early onset schizophrenia is a concern and children often have difficulty describing psychotic symptoms. One problem is distinguishing true psychotic phenomena in children from nonpsychotic idiosyncratic thinking, perceptions caused by developmental delays, exposure to disturbing and traumatic events, and overactive and vivid imaginations. There are major developmental differences in the perception of reality and developmentally or culturally appropriate beliefs (e.g., imaginary playmates and fantasy figures) that are not, of themselves, suggestive of psychosis. (2) Despite the relatively high (up to 5%) prevalence of psychotic symptoms in otherwise healthy children (3,4), COS is very rare and so epidemiologic incidence data with diagnoses based on standardized clinical assessments are lacking. It is generally accepted that the incidence of COS is less than 0.04% based on the observations from the National Institutes of Mental Health (NIMH) cohort. Approximately 30 to 50% of patients with affective or other atypical psychotic symptoms are

misdiagnosed as COS. (3) The treatment of early onset schizophrenia follows a similar approach like the adult onset schizophrenia. Most data on neuroleptic treatment of schizophrenia is from adult studies of typical and atypical neuroleptics. Sikich et al. conducted a double-blind study to compare the efficacy and safety of two second-generation antipsychotics (olanzapine and risperidone) with a first-generation antipsychotic (molindone) in the treatment of early-onset schizophrenia. The three treatment arms did not significantly differ in symptom reduction or time to discontinuation. Conclusion: The diagnosis of COS is very challenging and an early, accurate diagnosis of COS will have profound implications for treatment.

No. 136

Current Understandings of Concomitant Hoarding Disorder and OCD: A Literature Review

Poster Presenter: Tahira Akbar, M.D.
Co-Authors: Shabber Agha Abbas, Ghulam Sajjad Khan, M.B.B.S., Asghar Hossain, M.D.

SUMMARY:
Introduction: Hoarding disorder (HD) is a severe psychiatric disorder characterized by an extreme difficulty discarding or parting with possessions significantly compromising one's living spaces. The DSM-IV defined HD as part of the obsessive-compulsive disorder (OCD) spectrum, whereas the DSM-V separated the two disorders into distinct spectrums. Patients with HD and concomitant OCD represent a distinct manifestation of psychopathology although the evidence has not been conclusive regarding their characterization. We conducted this literature review to evaluate the evidence pertaining to such patients especially in the context of the new DSM-V definitions. Methods: A literature review was conducted on Pubmed, OvidMedline, Web of Science, and google looking for the terms 'hoarding disorder', 'obsessive' and 'compulsive', and/or 'ocd' in the same article. Articles solicited had to be published past the publication date of the DSM-V (May 2013) and had to be in English. Only those articles describing patients with comorbid HD and OCD were selected. Information pertaining to prevalence, characteristics, and treatment options was solicited from these articles. Results: Using the search parameters, 115 articles were identified of which 13 articles contained information fitting the patient criteria. Of the articles identified, eleven were primary articles and two were review articles. Some information gathered from our literature review confirmed earlier reported findings whereas some provided new insight regarding areas of comorbid disease clinical and non-clinical characterization. As reported in earlier studies the prevalence of comorbid HD and OCD in patients with either HD or OCD was found to be relatively high (16.5%-19.5%). An increase in severity of OCD symptoms was observed in HD patients. In addition, as reported earlier, response to treatment is poorer in comorbid patients than in those HD or OCD alone. Newer findings include identification of a bimodal presentation of OCD disease severity in HD patients (highest in youngest and in oldest HD patients), identification of similar level of cognitive difficulties in both disorders, a genetic correlation of 0.10, a phenotypic covariance of 50.4%, poorer response to limbic system surgery, gender differences, identification of OCD as a risk factor for HD development, and unique features of comorbid HD and OCD in the pediatric patient population. Conclusion: Patients with HD and concomitant OCD represent a unique subpopulation within both the hoarding and OCD spectrums. Although research has increased our understanding of differences between these patients and those without comorbid disorders relative to many areas, there remains a need to clarify treatment and management recommendations to enhance increased efficacy of both psychotherapies and pharmacotherapies. Our results may inform the design of various future clinical and non-clinical trials involving patients with these two disorders.

No. 137

Acute on Chronic Hoarding Disorder in a Geriatric Patient in the Context of Worsening Heart Disease: A Case Report

Poster Presenter: Renee L. Bayer, M.D., M.P.H.

SUMMARY:
The prevalence of hoarding is estimated at 2 to 6 percent among adults, tending to be older, unemployed, and single.1 The majority of patients have comorbid mental disorders, generalized anxiety

disorder, major depressive disorder and obsessive-compulsive disorder being the most common. 2 The patient is an 81-year- old Caucasian male, OCD treated with medication in his 40s, hypertension and benign prostatic hypertrophy, who called EMS after a fall in his home. The police officer on the scene reported: “residence full of trash and clutter… states he has not eaten since in three days. Junk prevented refrigerator from being opened all the way.…” The patient was admitted for weakness, and after a clinically significant EKG in the ED, significantly elevated CK troponin, BUN, and creatinine, diagnosed with NSTEMI, rhabdomyolysis, and AKI. He complained of feeling tired and weak in the last couple weeks. He denied difficulty disposing of items he does not need, and asked if his house is going to be condemned. Collateral information obtained from family confirmed hoarding behavior for 50 plus years, that worsened 10 years ago after his wife died, and stabilized. In the months prior to his admission, his family reports weight loss, and discontinued social activities. SSRIs have been effective in treating hoarding disorder, suggesting an association between decreased serotonin and worsening symptoms. The production of serotonin is known to be oxygen dependent. In fact, serotonin synthesis in the brain was measured using positron emission tomography with [11C]methyl-L-tryptophan as a tracer. Serotonin synthesis was higher when the participants were breathing 60% oxygen than breathing 15% oxygen. 3 A recent study explored the relationship between sudden or unnatural death and hoarding. Autopsy results showed that heart disease was the leading significant factor in 52% of all cases. 4 When compared by similar age group, only 33% of deaths were attributed to heart disease. 5 The difference in the incidence of heart disease suggests that hoarders may have a higher incidence of cardiac death. The hypothesis is that hypoxia, as in severe cardiac disease, may have contributed to the worsening hoarding symptoms due to associated decreased serotonin production. In this particular case, the acute worsening of his chronic hoarding behavior, with no obvious social trigger, may have been a harbinger of his underlying cardiac condition.

No. 138

Exacerbation of OCD Symptoms in the Context of Borrelia Burgdorferi Infection: Lyme Disease

Poster Presenter: Imran Samad Qureshi, M.D.
Co-Authors: Rachel Kossack, Asghar Hossain, M.D.

SUMMARY:
Abstract: Introduction: Lyme disease is a multisystem, inflammatory disease caused by the spirochete Borrelia burgdorferi and transmitted by the Ixodes Spp. tick. It is the most common arthropod-borne illness in the U.S. with the highest prevalence in the northeast. Patients usually present within the first month with fatigue, malaise, headaches, myalgias, arthralgias, with or without the characteristic erythema migrans rash. If left untreated, late disseminated disease may manifest as neuropsychiatric illness such as depression, anxiety, psychosis and obsessive compulsive disorder (OCD). Objective: The objective of our case report is to explore a possible association between Lyme disease and the development of psychiatric symptoms; in particular, sudden-onset relapse of OCD in a patient previously successfully treated in the context of infectious etiology. Case: This is a 18 year old Polish female who had a resolution of all OCD symptoms a year after starting fluoxetine 80mg. The patient then became non-compliant with psychotropic medication but still did not exhibit any OCD symptoms until 2 years later when she had a relapse of her OCD symptoms of obsessive hand washing and related rituals. A thorough history was taken and she reported symptoms of fatigue, migrating arthralgia and headaches 2 weeks after a hiking trip in New Hampshire. Blood tests confirmed Lyme and the patient was placed on antibiotics for 4 weeks beyond the resolution of her physical symptoms of Lyme. Once treatment for Lyme ended, the patient was started on a moderate dose antidepressant; Sertraline 100mg, and after 5 months had a complete res-olution of all OCD symptoms. Discussion: The Ixodes tick bite is painless and patients may only present with nonspecific flu-like symptoms, which makes the diagnosis of Lyme disease a challenge. The typical onset of OCD symptoms in patients without any prior infectious etiology is typically gradual, while a more acute onset presentation follows an infectious etiology in substantial number of cases. Neurosyphilis, caused by Treponema Pallidum, is another spirochetal infection that has been known

to cause onset of psychiatric illness in untreated patients such as psychosis, dementia and depression. Pathophysiological etiology of neuropsychiatric manifestations may be attributable to formation antibodies directed to brain cells precipitating psychiatric symptoms. Conclusion: This case report brings forth the intricacy of diagnosing and treating patients with an atypical presentation of OCD with a possible coincidental history of Lyme disease. By reviewing studies and exploring the neuroanatomical explanation of OCD as well as existing well studied models of neuropsychiatric symptoms developing from infectious etiology, we hope to support the plausibility of Lyme disease and OCD association with good response on moderate doses of SSRI's.

No. 139

Use of Citalopram in Post-Stroke Psychotic Depression in Context of Prolonged Comatose Phase: A Case Report

Poster Presenter: Imran Samad Qureshi, M.D.
Co-Authors: Asghar Hossain, M.D., Shabber Agha Abbas

SUMMARY:

Introduction: Post-stroke depression (PSD) is the most common neuropsychiatric sequel of a stroke and has a high prevalence rate (9% to 34%) in the initial post-stroke period. Apart from mood disturbances, the significance of PSD is its detrimental impact on post-stroke rehabilitation. Our case report addresses the role of serotoninergic therapy in PSD following a comatose state in context of cerebrovascular accident. Objective: The objective of this article is to report the successful treatment of PSD with citalopram in a patient recovering from a comatose state following intra-cerebral hemorrhage. Case: We report a 55-year-old Egyptian male who was referred to outpatient clinic by his primary care physician secondary to symptoms of depression. He was diagnosed with a brain tumor (occipital lobe) in 2014 and had surgical removal. Subsequently he developed an intracerebral hemorrhagic stroke and was in a comatose state for two months. Following recovery, he developed worsening symptoms of depression that abruptly progressed. He endorsed feeling tired and isolated and having nightmares, insomnia, depressed mood, hopelessness and anhedonia. He reported hearing voices, which were unrecognizable and non-command type in nature. He denied any suicidal or homicidal ideation. No other psychotic or manic symptoms reported. No substance abuse reported. He had a good response with 20 mg citalopram. Auditory hallucinations ameliorated in the absence of antipsychotics use. Subsequently, his depression remit with moderate dose of SSRI, and was well tolerated. Discussion: Post-stroke states themselves are associated with overall impaired functional outcomes, increased risk of suicide, and increased mortality. PSD and post-comatose effects can exacerbate post-stroke related difficulties. The association of depression and stroke is multifaceted and depends on the etiology including size, location and number of lesions, stroke subtype, stroke severity, social handicap, and family support. The role of selective serotonin reuptake inhibitors (SSRIs) in the post-stroke setting has been evaluated for both prevention and treatment of depressive symptoms; however, more robust studies are required for determining treatment recommendations. Additionally, there is paucity of literature addressing the treatment of PSD in the context of a post-comatose state. Since no study till date has explored the role of SSRIs in post-comatose patients, the positive response to citalopram therapy in our patient provides a rationale for potential further research into this area. Conclusion: Citalopram therapy may be considered in patients with post stroke depression who recovered from comatose states to help alleviate depressive symptoms. The role of citalopram and other SSRIs in this setting warrants further research to further explore treatment response.

No. 140

Bupropion-Induced Psychosis in Context of Alcohol Dependence: A Case Report

Poster Presenter: Imran Samad Qureshi, M.D.
Co-Authors: Sheema Imran, M.D., Mehwish Hina, Imran Samad Qureshi, M.D., Asghar Hossain, M.D.

SUMMARY:

ABSTRACT: BACKGROUND: Bupropion is an antidepressant with dopamine enhancing effect within synapses of brain. Precipitation of psychosis secondary to bupropion use is not a frequent presentation. Concurrent use of substances primarily

cocaine increases the chances for psychotic decompensation. Psychosis induced by bupropion in most circumstances is transient and may need only short term antipsychotic therapy for alleviation of psychotic symptoms with full recovery. OBJECTIVE: The primary objective of this case report is to study the association of psychosis with bupropion use. It also emphasizes how bupropion may unmask subtle psychosis in some patients due to its dopaminergic enhancing effect. CASE DESCRIPTION: 23 year-old Caucasian male presented to ER of our behavioral health facility with overt psychosis and disorganized behavior. Reportedly patient was expressing depressive symptoms of anhedonia, helplessness, low self-esteem and hopelessness along with depressed mood. He also had history of alcohol dependence in context of onset of his depression. He was recommended bupropion 150mg XL once daily by his primary care physician for depressive symptoms. After two weeks of compliance with this therapy he started experiencing persecutory delusions, thought blocking and disorganized behavior. He also exhibited irritability, agitation, and impulsive behavior which led him to binge drink. Subsequently he was admitted at our facility with florid psychosis, agitation and disorganized behavior. He was managed with low dose antipsychotic (risperidone) and cessation of bupropion therapy. This led to complete resolution of his psychotic symptoms. DESCRIPTION: Available literature reveals association of bupropion-induced psychosis with use of immediate release bupropion. On contrary, our case report reveals association of extended release formulation of bupropion with florid psychosis and disorganized behavior. Simultaneous use of specific substances specifically cocaine increases probability of psychotic decompensation. However in this case report patient had history of alcohol abuse, which is less likely to be the predisposing factor to psychosis. There have been cases reported with significant perception disturbances in context of overt psychosis induced by bupropion. Such cases show good response with low dose antipsychotics and cessation of bupropion therapy as seen in our case. It has been said that bupropion may unmask subtle ongoing psychosis or may uncover prodromal phase of schizophrenia when patient culminates into florid psychosis after starting bupropion. This has been debated and currently area of research interest. CONCLUSION: We conclude that prompt intervention in case of bupropion induced psychosis is imperative. Full recovery from psychotic episode is expected as seen in this case report. However cases where residual psychotic symptoms still persist after cessation of bupropion therapy, we recommend exploring underlying etiology

No. 141

A Case of Severe Hoarding Disorder-Challenges on an Inpatient Unit and Potential Repercussions in the Community

Poster Presenter: Mohammed Tashfiqul Islam, M.D.
Co-Authors: Ghulam Sajjad Khan, M.B.B.S., Shabber Agha Abbas, Asghar Hossain, M.D.

SUMMARY:
Introduction: As hoarding disorder is now a discrete diagnosis in the DSM-V various challenges arise in treating this condition especially for community providers. While committing these patients may be easy due to the danger they pose to themselves, others or property, additional challenges soon arise in the inpatient setting. With housing being a key component of many psychiatric admissions nationwide, the repercussions from hoarding disorder have the potential to impact availability of public housing for psychiatric patients, as well as potential public health hazards. Objective: This case highlights the potential severity of the danger posed by hoarding disorder. The unique aspects of this case include the psychosocial components contributing to the pathology, as well as comorbid personality traits that impact the patient's prognosis. In addition, the case highlights the challenges of providing care to such a patient on an inpatient setting and weighing treatment options with their perceived efficacy. Case: Patient is a 63-year-old Caucasian female who was committed involuntarily due to inability to care for herself. Historically, she has collected various items in her apartment. Prior to admission, she flushed cans down the toilet, and the apartment subsequently became flooded with sewage and was rendered uninhabitable. On the unit, she was needy, demanding, and often monopolized staff time and disrupted the care of other patients. She routinely made lists and letters, and was inflexible in her demands with regards to certain objects and possessions. Her hoarding behavior continued during

her inpatient stay. She was noncompliant with her medications and partially compliant with medical care. Given her treatment noncompliance, only psychotherapy proved aided in helping the patient gain insight into her conditions. Discussion: While it is believed to occur in 2-5% of the population, lifetime prevalence of hoarding is estimated to be as high as 14% according to some studies. The presence of hoarding behavior is seen in approximately 30% of obsessive compulsive disorder patients and are relatively common in schizophrenics. The presence of obsessive compulsive personality traits can further complicate care, as additional treatment modalities have to be considered, especially as in our case. While it may be uncommon to treat such a patient on an inpatient setting, community psychiatrists and assertive community treatment teams can coordinate long-term follow-up services with housing programs to ensure patient safety. Conclusion: Hoarding disorder presents unique challenges in psychiatry, especially from the perspective of community providers who have to weigh the pathology of patients with the acuity of dangerousness and coordinate with other providers to ensure proper care.

No. 142

Visual Hallucinations With Comorbid Flashbacks and Nightmares: Psychosis, Brain Injury, and Posttraumatic Stress Disorder (PTSD) Overlap

Poster Presenter: Mohammed Tashfiqul Islam, M.D.
Co-Authors: Shabber Agha Abbas, Ghulam Sajjad Khan, M.B.B.S., Asghar Hossain, M.D.

SUMMARY:
Introduction: Symptoms of psychosis and post-traumatic stress disorder (PTSD) often overlap. Given the relationship between trauma experienced (especially in early childhood) and the resulting association with psychosis, it is prudent to further explore the relationship between the two. Furthermore, physical trauma (namely brain injuries) have their own sequelae which are an important factor to explore in the development of psychosis. Objective: In this case report we aim to explore the relationship between psychotic symptoms and their relation to traumatic experiences. In particular, this case highlights a unique presentation of psychosis with visual hallucinations being the predominant symptom. These visual hallucinations are completely separate from flashbacks experienced as part of PTSD symptoms and raises interesting questions regarding the psychopathology of the disorder. Case: Patient is a 29-year-old West African male who presented to the emergency department for evaluation due to progressively worsening auditory and visual hallucinations over 2 weeks that caused marked impairments in daily functioning. His current symptoms began three years after he sustained a head injury (with loss of consciousness) in his home country during his childhood. The patient reported routinely experiencing flashbacks and nightmares related to traumatic childhood events. He also reported history of smoking cannabis on a regular basis, which further exacerbated his symptoms. He was admitted and stabilized on a regimen of risperidone and then discharged. Within two weeks of being discharged he again decompensated secondary to noncompliance and was readmitted. During the second admission he presented with more severe psychosis symptoms including grandiose delusions and religious preoccupation. He was stabilized on the same medication regimen and discharged after four days. Discussion: The majority of research in relation to visual hallucinations has been conducted in the context of various eye and neurodegenerative conditions, but there is little research to suggest their involvement in psychiatric conditions. As per one study, the weighted mean of visual hallucinations in schizophrenia is 27% and 15% in affective psychosis (with 7.3% for the general population), so this certainly challenges the popular notion that visual hallucinations are uncommon in psychosis. In addition, the lack of research linking the development of psychosis after experiences of trauma (both physical and emotional) presents opportunities for modifying existing treatment modalities for other psychiatric illnesses. Conclusion: The presence of visual hallucinations in the context of psychosis in addition to PTSD symptoms presents a unique opportunity to examine the relation between two separate yet overlapping disorders that can be potentially be complicated from the sequelae from physical trauma to the brain.

No. 143

Use of rTMS in Obsessive-Compulsive Disorder: A Review

Poster Presenter: Fatima Motiwala, M.D., M.P.H.

SUMMARY:
Introduction: Obsessive Compulsive Disorder (OCD) is a chronic psychiatric condition characterized by intrusive and repetitive thoughts (obsession) which provoke anxiety and it is accompanied by the compulsions to relieve anxiety. It can vary in severity. Refractory cases do not respond to medications and cause functional impairment for individuals affected by OCD. There are several pharmacotherapy and psychotherapy options to treat OCD but at times, OCD does not respond to any intervention. Repetitive Transcranial magnetic stimulation (rTMS) is a non-invasive procedure, in which repetitive magnetic stimulation is passed through the areas of brain with the coil placed on scalp. It has been used to treat many psychiatric disorders like mood disorders, anxiety, movement and tic disorders. Methods: Using search terms, " Repetitive Transcranial magnetic stimulation OR rTMS AND Obsessive compulsive disorder OR OCD" in the Pubmed database resulted in 52 hits. Inclusion Criteria: Clinical trials,open label studies, review articles and pilot studies examining the effect of rTMS on patients with OCD. Exclusion criteria: Treatment not involving rTMS. Results: After an initial abstract review, we found 11 randomized controlled trials (RCT), 4 open label studies, 3 review articles, 3 metanalysis and 2 pilot studies which showed the positive effect of rTMS on the reduction of OCD symptoms. In majority of RCTs, significant reduction of Yale-Brown Obsessive Compulsive Scale (YBOCS) score was a primary outcome. However there are 5 RCTs, 2 review articles 1 open label, and one case series which oppose the beneficial effects of rTMS on OCD symptoms. From our previous review article, we concluded that 2 RCTs showed reduction in OCD symptoms in patient having co-morbid Tourette disorder. rTMS has appeared to be safe especially in children and does not manifest many side effects. Discussion: rTMS appears to be a safe non-invasive procedure for refractory OCD cases. Majority of the clinical trials showed improvement in symptoms of OCD as measured by significant reduction in YBOCS score. Patients with OCD have also shown improvement in cognitive function after rTMS treatment. There is a evidence that rTMS has a also been used as an augmenting treatment to treat OCD and has shown to improve depression, which frequently manifets as a co-morbidty of OCD. Conclusion: rTMS has shown to be effective in reducing the symptoms of OCD, but since OCD exists with other psychiatric disorders, it is important to observe and examine the effects of rTMS on co-morbid psychiatric conditions along with OCD. We need to evaluate in detail if these co-morbid psychiatric conditions or medications can be confounding factors or barriers in non-respondent cases.

No. 144

Use of Gabapentin in Anxiety Disorders

Poster Presenter: Fatima Motiwala, M.D., M.P.H.
Co-Author: Dinesh Sangroula, M.D.

SUMMARY:
Introduction: Gabapentin also called as Neurontin belongs to an antiepileptic group of medications. Besides its use in the treatment of epilepsy, neuropathies (including diabetic neuropathy and post-herpetic neuralgia) and pain disorders like fibromyalgia, it is also commonly prescribed by primary care providers for insomnia, anxiety and mood disorders. Gabapentin is an amino-acid derivative of gamma-amino butyric acid (GABA) and it also increases the production of GABA which is an inhibitory neurotransmitter, although it does not act on GABA receptors). Gabapentin acts through alpha2delta subunit of calcium channels. Common side effects are headache, dizziness, somnolence and dry mouth. It is considered to be safe since it has less abuse potential than Pregablin(shares common structure with Gabapentin). Methods: Our initial literature search in Pubmed database resulted in 218 hits, using search terms: (Gabapentin OR Neurontin) AND (Anxiety disorder OR GAD OR Generalized Anxiety Disorder OR Panic Disorder OR Panic Attack). Inclusion criteria: review articles, clinical trials, cohort studies, case reports/ series and animal studies supporting the use of Gabapentin in anxiety disorders including Generalized Anxiety Disorder (GAD), Panic Disorder and Panic Attack. Exclusion criteria: studies with patient population suffering from Post-traumatic stress disorder(PTSD), or have co-morbidities with substance abuse disorder. Results: After an abstract review, we concluded 21 review articles generally mentioning the use of

Gabapentin in anxiety disorders, 12 review articles which were specific and have emphasized on its positive effect on anxiety. We found 10 animal studies,5 clinical trials (one specific to social phobia), 1 case series and 2 cohort retrospective studies supporting Gabapentin use in anxiety disorders. We reviewed articles pertinent to Gabapentin use in Panic disorders separately and our search resulted in a one clinical trial, 1 case report and 1 case series. On the other hand, we found one case series, two clinical trials showing results opposing the beneficial effects of Gabapentin in anxiety disorders. Although PTSD was an exclusion criteria, we found weak results of Gabapentin's use in PTSD. Other case reports drew our attention to rare side effects of Gabapentin like Chorea (n=2), Delirium and dependence (n=1), Hearing loss (n=1), and bilateral leg edema (n=1) Discussion: Gabapentin belongs to a class of medication which is used to treat epilepsy, pain disorders and neuropathy. Besides this, it has also been frequently prescribed for psychiatric disorders like mood disorders, and anxiety disorders especially in Social phobia. It is considered relatively safe which is evident by its use in elderly people for insomnia and agitation related to dementia, as the use of benzodiazepi

No. 145

The Relationship Between Anxiety Sensitivity and Nonsuicidal Self-Injury in Patients With Social Phobia, Agoraphobia, and Simple Phobia

Poster Presenter: Safiye Bahar Ölmez

SUMMARY:

Background: Nonsuicidal self-injury (NSSI) is frequently observed in phobias like other anxiety disorders. Besides different phobia types can have different anxiety sensitivity characteristics. The purpose of this study was to investigate the relationships between anxiety sensitivity and NSSI in patients with social phobia, agoraphobia and simple phobia in the category of anxiety disorders. Methods: The sample consisted of adult outpatients with a phobia (age 18-65) in addition to healthy individuals (age 18-65) who had not received any psychiatric diagnosis serving as the control group. The outpatients with only one of social phobia, or agoraphobia, or simple phobia were diagnosed based on American Psychiatric Association Diagnostic and Statistical Manuel of Mental Disorders fifth version (DSM-5) criteria. As data collection tools, the sociodemographic form, the Inventory of Statements about Self-Injury (ISAS), the Anxiety Sensitivity Index (ASI-3) were used. Results: This analysis included 42 patients with social phobia (mean age=21.0, 57.1% male) and 27 patients with agoraphobia (mean age=40.0, 33.3% male), 40 patients with simple phobia (mean age=33.5, 35.0% male) and 51 healthy individuals as the control group (mean age=26.0, 31.4% male). Total ASI-3 mean scores in all three phobia groups were higher than the control group (p=0.002 and p=0.001, respectively). The total score of ISAS was higher in the social phobia group (p=0.025). Cognitive anxiety sensitivity sub-scores of agoraphobia and simple phobia groups were higher than the control group (p=0.001 and p=0.001, respectively). There was also a positive correlation between ISAS functions sub-scores and cognitive anxiety sensitivity sub-scores in agoraphobia and simple phobia groups (r=0.784, p=0.037 and r=0.617, p=0.014, respectively). Conclusions: Different anxiety sensitivities and NSSI characteristics can be observed in different phobia types. In addition, anxiety sensitivity can play a regulatory role between anxiety and NSSI of phobia patients. Cognitive anxiety sensitivity can have an important role for dealing with anxiety. Patients with agoraphobia and simple phobia who have higher cognitive anxiety sensitivity, have a high potential of showing NSSI rather than behavioral inhibition for dealing with anxiety.

No. 146

A Comparison of Childhood Emotional Abuse and Emotional Neglect History in Patients With Panic Disorder and Control Group

Poster Presenter: Safiye Bahar Ölmez
Co-Author: Ibrahim Burak Ölmez

SUMMARY:

Background: It is widely known that childhood traumatic experiences are associated with most of the adult life psychiatric disorders such as disassociative disorders, mood disorders, anxiety disorders and so on. In this study, the relationship between childhood traumatic experiences and panic disorder development was examined with regards to all types of traumas including sexual abuse, physical

abuse, emotional abuse, emotional neglect, and physical neglect. Method: The sample for this study consisted of 59 outpatients with panic disorder (age 18-65) and 61 healthy individuals (age 18-65) serving as the control group. These individuals in the panic disorder group were selected from outpatients who had been diagnosed with panic disorder based on American Psychiatric Association Diagnostic and Statistical Manuel of Mental Disorders fifth version (DSM-5) criteria and who did not have been diagnosed any other psychiatric disorder. The 61 healthy individuals in the control group were selected from medical staff and hospital attendants who had not received any psychiatric diagnosis or treatment. The individuals in both groups volunteered to participate in this study, and written informed consents were obtained from each of them. As data collection tools, the socio-demographic form, and the Childhood Trauma Questionnaire (CTQ) were used. Results: The main finding we report is that the individuals in the panic disorder group were found to have significantly high scores in comparison to those in the control group with respect to the total CTQ score (p=0.006) and specifically, the emotional neglect (p=0.004) and the emotional abuse sub-scores (p=0.009). Besides the increase in the number of siblings is significantly related to the increase in physical neglect and sexual abuse (r = 0.335 and r = 0.372, respectively). When we consider the relationship between duration of disorder and childhood traumatic experiences, a positive relationship was found between the duration of disorder and physical neglect (p = 0.022), and no significant relationship appeared between the duration of disorder and CTQ total score (p > 0.05) Conclusions: The main result of this study is that panic disorder is a mental disorder in which childhood traumatic events play a critical role in its developmental process. Also obtaining significantly higher emotional abuse and emotional neglect in patients with panic disorder with regards to healthy individuals seems to be a precursor for the identification of a psychiatric disorder group with respect to the type or quality of trauma in childhood.

No. 147

An Investigation of Impulsivity and Nonsuicidal Self-Injury Characteristics of Patients With Social Phobia

Poster Presenter: Safiye Bahar Ölmez

SUMMARY:

Objective: In this study, it was aimed to investigate the relationship between impulsivity, and nonsuicidal self-injury (NSSI) characteristics in patients with social phobia. Methods: The sample consisted of outpatients (n=41) (age 18-65) in addition to healthy individuals (n=52) (age 18-65) who had not received any psychiatric diagnosis serving as the control group. The outpatients with Social Phobia were diagnosed based on American Psychiatric Association *Diagnostic and Statistical Manuel of Mental Disorders* fifth version (*DSM-5*) criteria. As data collection tools, the socio-demographic form, the Barrat Impulsivity Scale (BIS-11), the Inventory of Statements about Self-Injury (ISAS), and the Liebowitz Social Anxiety Scale (LSAS) were used. Results: BIS-11 mean total scores in Social Phobia group were higher than controls (p=0.001). NSSI was 38.6% in the social phobia group, while it was 11.7% in the control group. Besides total score of ISAS was higher in the Social Phobia group (p=0.025). On the other hand contrary the expectations there is no correlation between ISAS and BIS-11 scores in groups. When we investigated the relation between impulsivity and symptom severity in social phobia group; there was a negative correlation between BIS-11 attention sub-scales score and LSAS avoidance sub-scale score (r =-0.353, p =0.022). Conclusions: Clinicians should question the anxiety coping behavior of patients with social phobia in detail in the mental state examination. Impulsivity can serve as a maladaptive way for patients with social phobia to deal with social anxiety. NSSI also can be a type of this maladaptive way. Besides, attention-related impulsivity may also increase typical withdrawal behavior symptom severity of patients with social phobia.

No. 148

Bugs From the Brain: A Different Approach to Treating Delusional Parasitosis

Poster Presenter: Anshul Pandey, M.D.

SUMMARY:

Introduction: Delusional Parasitosis is an uncommon disorder characterized by a false belief that the

patient's body is infested by parasites. Hard to treat and involving multiple disciplines: treatment is a long process and does not guarantee a cure. But, if the delusions lead to an obsessive-compulsive syndrome with poor insight, could targeting the OCD component produce better outcomes in overall care? Case: Patient is a 32-year old woman with a previous history of MDD, Borderline Personality disorder and a remote history of methamphetamine abuse, who was seen as an outpatient for medication management and psychotherapy. She was recently discharged from the Psychiatry unit after a suicide attempt. She was discharged from the hospital on quetiapine for mood stabilization, and mirtazapine for depression. Sessions continued with raising her mirtazapine dose and focused supportive psychotherapy. After a few sessions, she started to report a mite and tick infestation in her house. Her sessions progressed with her obsessions with the infestation worsening and leading to her being holed up in her home all day, wearing only hooded garments, gloves and multiple layers of clothing, and cleaning her home for 5-6 hours daily. Gradually she was covered in scabs and scratches all over her body, showing this as proof of the presence of the parasites. Suspecting delusional parasitosis, a referral to Dermatology was made which confirmed the diagnosis. She was started on pimozide, but her symptoms did not improve. Noticing the co-existing, deteriorating lifestyle with repetitive cleaning daily, social isolation fall-out with family, a different approach was tried. What if her lifestyle was a result of OCD with very poor insight? Would targeting her OCD-like symptoms help improve her lifestyle or possibly even the delusional parasitosis? She was started on fluoxetine and the dose was gradually increased to higher doses. Gears were switched to more OCD-focussed CBT. Slowly, a response was visible. Her obsessions with the parasites decreased in intensity and her compulsion to clean went down significantly. She leaves her house more often now, is back in society once again and feels better overall. Her insight regarding her obsessions and compulsions has improved. Unfortunately, her delusions about parasitosis have not improved but she is more open to the idea of a delusional pathology now. Most importantly, her distress from the obsessions and the compulsions of cleaning has improved significantly. Conclusion: Delusional Parasitosis is very difficult to treat and the delusions rarely improve or get eradicated. But, an approach to target the symptoms arising from the delusional pathology, as in our patient's OCD-like syndrome, would bring significant relief to the patient's life and prevent or treat significant morbidity associated with Delusional Parasitosis.

No. 149

Anxiety and Depression in Patients With Chronic Kidney Disease in Limassol, Cyprus

Poster Presenter: Dimitris Avramidis
Lead Author: Konstantinos Argyropoulos
Co-Authors: Giorgos Charalambous, Panagiota Faidonos, Antri Aresti, Argyro Argyropoulou, Giannis Gastouniotis, Eleni Jelastopulu

SUMMARY:
Introduction Populations facing chronic illness have been reported to have poorer quality of life and mental health, including higher levels of depression and anxiety. Purpose The purpose of the present study was to estimate differences referring in the presence of anxiety and depression in two groups of renal disease patients. Moreover, to investigate the relationship of sociodemographic variables such as gender, age, educational level and family status to mental health. Material - Method: A sample of 230 patients were recruited, consisting of 130 patients undergoing hemodialysis (HD) and 100 patients with successful kidney transplantation (KT). The instrument used to assess the anxiety and depression levels was the in Greek translated and validated Hospital Anxiety and Depression Scale (HADS). The absolute score for each component ranges from 0-21, and for overall psychological distress from 0-42, consistent with low to high levels of anxiety, depression or both respectively. Statistical analyses were performed using the SPSS v. 19.0. Results: Patients with HD scored overall higher on the HADS compared to patients with KT (13.52 vs 10.30). Both patient groups showed higher mean scores in depression (HD: 8.85; KT: 6.20), whereas lower scores were observed in the anxiety component (HD 4.67; KT 4.10). No statistically significant differences were found in the mean value of anxiety (t=1.16, p=0.249) between both groups. Regarding depression and the overall score we observed statistically significant differences in the

mean values for depression (t=3,86, p <0,001) and for the overall HADS score (t=3,12, p=0,002) between the patients undergoing hemodialysis compared to patients with KT. Investigating gender differences, female patients scored higher in all dimensions and in both groups compared to males (HT: HADS 16.10 vs 11.91, Anxiety 6.40 vs 3.58, Depression 9.70 vs 8.33; KT: HADS 11.20 vs 9.70, Anxiety 4.30 vs 3.97, Depression 6.90 vs 5.73), being statistical significant only in the group of HT patients. In patients with KT older ages, lower educational level, being divorced or widowed and being retired scored significantly higher, whereas in HT patients only educational level and marital status play a significant role. Conclusions: In the present study, the overall HADS score as well as the single component scores of anxiety and depression were higher in patients with HT, indicating thus the higher psychological discomfort in these patients. Furthermore, the scores were associated with demographic parameters such as gender, age, educational level, marital and occupational status.

Electroconvulsive Therapy for Obsessive-Compulsive Disorder: A Case Report and Review of the Literature

Poster Presenter: Justin LaPorte, M.D.
Co-Author: Thomas A. Veeder, M.D.

SUMMARY:
Mr. S., a 27-year-old Caucasian male with prior history of obsessive-compulsive disorder (OCD) was admitted for his second inpatient psychiatric treatment following medical clearance for a near-lethal salicylate overdose (OD). Upon admission, Mr. S. endorsed one year of persistent, intrusive, and ego-dystonic thoughts of death and suicide in addition to ruminative and extreme self-doubt and over-analysis. He additionally noted two months of depressed mood, poor sleep, hopelessness, poor appetite, and anhedonia, culminating in his suicide attempt. He was diagnosed with OCD and comorbid Major Depressive Disorder (MDD). Due to the severity of his symptoms and lack of treatment response on several pharmacologic agents (fluvoxamine, duloxetine, aripiprazole, risperidone, and doxepin), a referral for electroconvulsive therapy (ECT) was made. After eight index treatments, Mr. S. had full remission of his OCD and depressive symptoms. He presently takes no medications and is stabilized on once monthly, maintenance ECT treatments. While there is inconsistent data to suggest that ECT is an effective treatment for OCD, herein lies a case of complete remission of OCD and depressive symptoms, achieved using ECT treatment.

No. 151

Differences in Psychiatric Symptoms Depend on Tinnitus-Related Characteristics and Gender in Tinnitus Patients

Poster Presenter: Tae Sun Han
Co-Authors: Jung Jin Kim, Jo-Eun Jeong, Shi-Nae Park

SUMMARY:
Objective: Previous studies regarding gender differences in terms of tinnitus distress have shown conflicted results. Therefore, this study aimed to evaluate the correlation between the severity of tinnitus and psychiatric comorbidities, and the gender differences in tinnitus patients. Study design: This cross-sectional study included 136 female and 119 male patients who visited Seoul-Saint- Mary`s hospital Otology outpatient clinic for tinnitus from February 2015 to July 2015. Patients were submitted to series of instruments, including Tinnitus handicap index(THI), Beck depression inventory(BDI), Brief Encounter Psychosocial Instrument-Korean version(BEPSI-K), and Visual analogue scales(VAS) to assess the duration and loudness of tinnitus, and the patients' awareness and degree of annoyance. Results: THI scores are added to yield a classification of the tinnitus handicap, from Normal (0 to 16), mild (18 to 36), moderate (38 to 56), and severe (58 to 100). Among the tinnitus severity groups, BDI and BEPSI-K were higher in the severe group than normal, mild, and moderate groups. There was a significant correlation between tinnitus severity(THI) and the duration and loudness of tinnitus, patients' awareness and degree of annoyance, the influence on life, and stress index(BEPSI-K) caused by tinnitus. In regression analysis, the influence on life, depression scale(BDI), stress index(BEPSI-K) affect the severity of tinnitus as an independent variables. Although women were more depressed than men on depression scale(BDI), correlation efficient between depression scale(BDI), stress index(BEPSI-K) and

tinnitus severity(THI) were higher in men when controlling age and duration of tinnitus on partial correlational analysis. Conclusion: The severity of tinnitus was significantly correlated with depressive symptoms and stress index, and gender differences were found in correlation between tinnitus severity and psychiatric symptoms. Considering these differences, gender-tailored therapy could be meaningful in such patients. Applying self-reported scale for depression symptoms to all patients visiting otology outpatient clinic could be done in order to screen and assess those who are in need of psychiatric support.

A Comparison of the Clinical Characteristics of Panic Disorder With and Without Generalized Anxiety Disorder

Poster Presenter: Jongsoo Oh
Co-Authors: Sang-Hyuk Lee, Tai-Kiu Choi, Jeong Hoon Kim

SUMMARY:

Background: Strong comorbidity occurs between panic disorder and generalized anxiety disorder. This study aimed to investigate differences in demographic, clinical characteristics, and quality of life between panic-disorder patients with generalized anxiety disorder (PD+GAD) and without generalized anxiety disorder (PD-GAD). Methods: We examined data from 218 patients diagnosed with PD+GAD(150 patients) and PD-GAD(68patients). The following instruments were applied: Stress coping strategies, Beck Depression Inventory(BDI), Beck Anxiety Inventory(BAI), Panic Disorder Severity Scale(PDSS), Anxiety Sensitivity Index-Revised(ASI-R), Albany Panic and Phobia Questionnaire(APPQ), NEO-neuroticism(NEO-N), Short Form health survey-36(SF-36). Results: Compared to the PD-GAD group, the PD+GAD group had higher scores in emotion-focused coping strategies and clinical severity, such as BDI, BAI, PDSS, ASI, APPQ, and neuroticism. The PD+GAD group showed lower scores in most scales in SF-36 status than PD-GAD group. Conclusion: This study shows that PD+GAD patients are different from PD-GAD patients in coping strategies, clinical severity and quality of life. It emphasizes the need of personalized therapy in clinical approach among patients with PD+GAD.

No. 153

Positive Correlation Between Early Trauma and Anxiety Sensitivity in Patients With Panic Disorder

Poster Presenter: Jongsoo Oh
Co-Authors: Sang-Hyuk Lee, Tai-Kiu Choi, Jeong Hoon Kim

SUMMARY:

Background: Early trauma is associated with increased risk of panic disorder(PD). It has long been recognized that anxiety sensitivity plays a important role in the panic disorder. The object of this study is to investigate the relationships between early trauma and anxiety disorder in patients with panic disorder. Methods: Ninety-five patients(mean age=38.01, 42.5% male) with PD were included. The following instruments were applied: Anxiety Sensitivity Index-Revised(ASI-R), Early Trauma Inventory (ETI). Results: ASI-R scores correlate positively with ETI scores in patients with panic disorder (r=0.351, p=0.001). Also, ASI subscale such as respiration(r=0.300, p=0.003), public(r=0.359, p<0.001), cardiac(r=0.257, p=0.012), cognition(r=0.296, p=0.003) correlate positively with ETI score in patients with panic disorder Conclusion: We showed that positive relationship between early trauma and anxiety sensitivity in patients with panic disorder. Further study is required with larger sample sizes.

No. 154

Anxiety and Depressive Symptoms Evaluation in Bariatric Surgery Candidates

Poster Presenter: Luiza Schmidt Heberle, M.D., M.S.
Co-Authors: Karin Mombach, Alexandre Padoin, Carolina Goldman Bergmann, Lívia Nora Brandalise, Luciano Billodre Luiz, Juliana Azevedo, Denise do Prado Bystronski, Alberto Kerber, Cesar Luis de Souza Brito

SUMMARY:

Background: Obesity and psychiatric disorders are likely to exert considerably negative impact on the quality of life of patients. In this regard, one may observe a high incidence of anxiety disorders in obese patients, particularly among candidates for bariatric surgery. Anxiety and depressive symptoms, as well as substance abuse are a substantial threat to

successful results following bariatric surgery. Objectives: To evaluate the association between the intensity of anxiety symptoms and body mass index, depressive symptoms and alcohol and tobacco use in obese patients who apply for bariatric surgery. Setting: Center of Obesity and Metabolic Syndrome at the Pontifical Catholic University of Rio grande do Sul, Brazil. Methods: Cross-sectional study involving 425 patients that have applied to bariatric surgery. Levels of anxiety and depression were assessed by the Beck Anxiety Inventory and the Beck Depression Inventory. Alcohol use was assessed by Alcohol Use Disorders Test and tobacco use by the Fagerström Test of Nicotine Dependence. Results: Among the 425 patients, 33.4% scored BAI above the cut-off point, while 59.3% scored BDI above the cut-off point. A significant statistic association between anxiety and depressive symptoms (P <0.001) was found. A statistically significant, direct and weak correlation between BAI scores and BMI was found. No patient presented AUDIT above the cut-off point and 4.7% were smokers. Conclusions: The high prevalence of anxiety and depressive symptoms detected is alarming and shows how much bariatric surgery candidates are subject to emotional suffering. The low prevalence of alcohol and tobacco use confirms findings of other studies.

No. 155

Skin and Thickness: The Containing Function in Obesity

Poster Presenter: Luiza Schmidt Heberle, M.D., M.S.
Co-Authors: Juliana Azevedo, Karin Mombach, Luciano Billodre Luiz, Lívia Nora Brandalise, Denise do Prado Bystronski, Alberto Kerber, Carolina Goldman Bergmann, Cesar Luis de Souza Brito

SUMMARY:

Objective: The skin plays a key role in the primary organization of the psyche. The purpose of this study is to review the following concepts: setting-up of inner versus outer space, contact boundary, excitability boundary and containing function. **Methods:** In weekly meetings at the Center of Obesity and Metabolic Syndrome at the Pontifical Catholic University of Rio Grande do Sul, Brazil, our group conducted a literature review and discussed the approaches of Freud, Esther Bick, Didier Anzieu and Winnicott on the experiences of the baby with its skin while developing archaic object relationship. In doing so, we sought to reflect on the correlation between the process of gaining weight and the need to develop a second-skin. **Results:** We managed to understand the importance of the skin in the development of the functions related to containing function, excitation screen, supportability and that of sustaining the parts of the self, according to the aforementioned authors. We also regarded the significance of the maternal envelope, including the touch, as the founding element of the thinking ego (moi-pensant), which contains parts of the self and enables the development of the symbolizing capacity. Through this understanding, we were able to evaluate the role played by the thickness of the skin in obese patients—that of a need to contain parts of a poorly integrated self, which was not able to develop a notion of containing object that would allow a self-other differentiation and proper identity conformation. **Conclusion:** The need of the obese to increase the thickness of their skin (fat layer) is so often the bodily expression of their need to create a protective and restraining cover, so as to keep splitted the emotional contents from inside and outside of their emotional lives. Thus, psychotherapy aims to amplify the patients' need to connect with the loved objects, introjecting and enhancing continence functions, as if developing a new skin.

No. 156

Multifactorial Presentation of Psychotic Depression in a Refugee: A Case Report

Poster Presenter: Mehwish Hina
Lead Author: Tahira Akbar, M.D.
Co-Author: Asghar Hossain, M.D.

SUMMARY:

Background: Immigrants or refugees sustain three fold chances of developing psychosis when compared to general population. Psychiatric symptoms ranging from anxiety to overt decompensation to psychotic depression or schizophrenia can impinge deleterious effect on one's mental health especially in context of migration. Coming as a refugee from a less developed country poses great challenges to anyone and survival depends much on the extent of coping skills and social support. Underlying multifactorial etiologies precipitating psychiatric symptoms

primarily includes unemployment, financial constrains and language barriers. Refugees coming from countries with civil unrest and war carries much higher chance to decompensate. Objective: The objective of this article is to report a challenging case of psychotic depression in a Syrian refugee with underlying diagnosis of posttraumatic stress disorder (PTSD). It also emphasizes the need of adapting effective management strategy to prevent further decompensation in such patient population. Case Description: 57 yo Syrian M who sustained PTSD following an unfortunate incident where his family was killed in front of him precipitating PTSD during times of war. He was hospitalized but was partially treated for his depression and flash blacks from the event. Later, he was migrated to United States and due to numerous psychosocial stressors decompensated to psychotic depression and admitted to our facility. He was managed aggressively with antidepressants, alpha-blocker and antipsychotics with subsequent referral to individual therapy and partial program for enhancement of his coping skills. Discussion: Multiple research articles exhibit the potential of psychotic decompensation in migrants or refugees. The correlation of PTSD to psychotic depression has been a challenge in clinical practice and various resistant cases of PTSD have been reported in this regard. The additional stress of being a refugee or a migrant complicates the situation in many instances if not managed appropriately. Treatment optimization plays a pivotal role in dealing with recurrent flashbacks from PTSD and prevents culminating into psychotic depression. Our case emphasizes the significance of effective management of any co-existent psychiatric disorders in migrants, which could potentially lead to more florid symptomatology if not promptly treated. Conclusion: The main emphasis of this case report is to highlight the multifactorial aspects of psychotic depression in migrants or refugees. PTSD has been a growing challenge in such population, and if not treated promptly may culminate into various psychiatric symptoms. In this case report, a Syrian refugee who was inadequately treated for his depression and PTSD, when migrated to United States decompensated to psychosis. This substantiates the importance of adequate treatment and enhancement of coping skills to negate further deterioration of psychiatric symptoms in such cases.

No. 157

Management of Treatment-Resistant Posttraumatic Stress Disorder (PTSD): A Systemic Review

Poster Presenter: Mehwish Hina
Lead Author: Tahira Akbar, M.D.
Co-Author: Asghar Hossain, M.D.

SUMMARY:

ABSTRACT: Posttraumatic stress disorder (PTSD) is increasingly common psychiatric disorder today impacting more than 10 % of population across United States. Various etiological factors can precipitate its symptoms ranging from abuse to sustaining horrific events during war times. Frequency of flash backs can be an index of stratifying severity of disorder as its affect functional status of the patient. SSRI primarily paroxetine and sertraline are the recommended (FDA-approved) anti depressants which have shown efficacy in various clinical trials. Maintenance treatment for 6-12 months decreases chances of relapse significantly. In most cases, pharmacotherapy with antidepressant is safe and effective; however, in selective cases patient fail to respond to it challenging physician to consider alternative treatment modality. Recently mood stabilizers, antipsychotics and alpha-blockers have been used in resistant cases. These medications primarily used as augmentative treatment modality along with antidepressants to improve the outcome of the illness. Among them prazosin (alpha blocker) is a well-tolerated medication which helps alleviating nightmares and flashbacks in patient experiencing PTSD. Doxazosin has the advantage over prazosin because of its long half-life. These alpha-blockers also help in sleep and reduce patient's hypervigilance. Numerous patients also experience overwhelming anxiety attributable to frequent nightmares and flashbacks prompting intervention with anxiolytics. Short course of benzodiazepines has a good effect on symptomatology in initial phase of PTSD. Psychotherapy has also significant role in managing this disorder. Cognitive Behavioral Therapy (CBT) is very instrumental and may require fine expertise of the practitioner. Trauma focused psychotherapy for posttraumatic stress disorder has shown very promising result especially when combine with pharmacotherapy. Prompt and

effective treatment of PTSD is very imperative to minimize the impact of illness on patient's social functioning and untreated cases may lead to significant psychiatric issues like major depression, panic disorder and psychosis. Untreated PTSD may also have deleterious consequences and could precipitate serious mental health crisis including suicide. Augmentative strategy with combination regiment along with trauma-focused psychotherapy is cormer stone of management in resistant cases of PTSD primarily in veterans.

No. 158

"I Can't Breathe": The Case of Factitious Disorder in 65-Year-Old Woman With Multiple Admissions

Poster Presenter: Asa L. Cheesman, M.D.
Co-Authors: Sina Shah, M.D., Raj V. Addepalli, M.D.

SUMMARY:
This case presents a 65 year old woman, who on initial presentation was complaining of multiple somatic symptoms. She was in obvious distress, breathing rapidly, moaning, difficult to engage. Also repeatedly reporting shortness of breath, inability to swallow, leg weakness, abdominal pain and constipation. Patient has had multiple previous medical admissions in multiple hospitals within the past 8 months with similar presentation. She was last admitted to another hospital one month prior and full workup for shortness of breath, chest pain, cough, dysphagia, UTI and bronchitis was done. Possible diagnosis of Somatic Symptom Disorder was made and patient was lost to follow up. She was admitted to psychiatry inpatient at a different hospital due to her persistent amplification of nonspecific somatic symptoms, lack of supportive physical findings, apparent anguish, refusal to eat or drink and her continued evasiveness during evaluations. Lack of clear objective markers made it difficult to diagnose the patient, therefore, Somatic Symptom Disorder and Delusional Disorder were considered. She responded to Olanzapine 5 mg at bedtime and supportive therapy. Exacerbation of symptoms with the presence of a physician, inconsistent compliance and response to treatment, no prominent secondary gain and excessive clinical history contributed to the diagnosis of Factitious Disorder. This stresses the importance of close observation, obtaining collateral information from family and previous admissions to make the diagnosis of Factitious Disorder.

No. 159

Use of Fluvoxamine Augmentation for Relief of Clozapine-Induced Constipation

Poster Presenter: Sina Shah, M.D.
Co-Author: Raj V. Addepalli, M.D.

SUMMARY:
This is a case of a 38 year old woman with psychiatric history of schizoaffective disorder on clozapine who presented to our hospital complaining of severe constipation, depression, and command auditory hallucinations to kill self. The patient was admitted to the inpatient psychiatric unit and continued on clozapine treatment. While perceptual symptoms resolved shortly after administration of clozapine 550 mg/day, symptoms of depression and constipation persisted. Despite administration of multiple stool softeners and bowel regulating agents, there was little improvement of constipation, causing the patient significant distress. Medical and Gastroenterology consult team recommendations for relieving constipation included discontinuation of clozapine due to the antimuscarinic side effects. The patient was reluctant to discontinue clozapine, as trial of other antipsychotics had failed in the past, and clozapine was the only agent that effectively treated her psychiatric symptoms. Augmentation of clozapine with asenapine 10 mg/day helped in resolution of psychiatric symptoms. Subsequently the dose of Clozapine was reduced to 250 mg/day, and fluvoxamine 100 mg/day was added to the regimen. This allowed the substantial reduction of clozapine dosage and maintenance of therapeutic clozapine levels and subsequent improvement of debilitating constipation. We discuss our strategy to ameliorate the antimuscarinic effects of clozapine and improving compliance by decreasing dosage of clozapine. This was primarily achieved by making use of the drug interaction of fluvoxamine with clozapine in a beneficial way. Fluvoxamine inhibits cytochrome P450(CYP)1A2 for which clozapine is a substrate, and results in maintenance of therapeutic levels of norclozapine and total clozapine levels at lower doses of clozapine. The outcome in our case was relief of severe constipation along with resolution of

psychotic symptoms by ameliorating the antimuscarinic effects of clozapine using its drug interaction with fluvoxamine.

No. 160

Successful Benzodiazepine Dose Reduction in Elderly Patient With Anxiety, Depression, and Multiple Medical Comorbidity

Poster Presenter: Soyoung Lee, M.D.

SUMMARY:

Patient is a 90-year-old female with a long-standing anxiety and depressive disorder who has been in treatment for 50 years. Patient has tried multiple medications, including different types of antidepressants, anxiolytics, mood stabilizers, and antipsychotics over the past 50 years. Currently, she is taking clonazepam 1mg PO TID for anxiety and nortriptyline 25mg PO nightly for depression and anxiety. She reports chronically depressed mood and anxiety that have been moderately well-controlled with her current regimen. Her presentation is further complicated with bilateral upper extremity tremor that worsens with anxiety, chronic musculoskeletal pain that requires narcotic pain medication: Percocet 10mg PO TID, recent falls, and worsening memory over the past decade. She needs assistance in some of her IADLs and ADLs due to her physical disability. MOCA test showed her cognitive function is compromised (MOCA = 22/30). Given her advanced age that makes her prone to have medication side effects especially from the concomitant use of benzodiazepine and narcotic pain medications, also with concerns of cognitive decline, plan was made to reduce the dose of clonazepam and to eventually discontinue. Patient understood the risks of using benzodiazepines and agreed with the plan. Initially, her current use of clonazepam was thoroughly assessed. She takes clonazepam 1mg TID, and she requires additional dose for severe anxiety occasionally. Counseling and psychoeducation were provided to build a rapport and to motivate the patient to actively participate in treatment plan. Gabapentin 100mg PO daily was added to help her anxiety symptoms. She was instructed to take gabapentin for severe anxiety. After 2 weeks, she reported that she cannot tolerate gabapentin because of feelings of dizziness and imbalance. She adhered to the TID dosing of clonazepam although she had to stop gabapentin. Afterwards, she continued to follow the tapering schedule that reduces the clonazepam by about 15% per month. During the tapering schedule, her mood has been stable without worsening depression. Supportive psychotherapy and psychoeducation was provided on every visit to relieve anxiety. A calendar table was made for her to record her clonazepam use, which motivated and improved her compliance. After 4 months, she is stable on clonazepam 0.5mg PO BID. Our plan is to continue to reduce and to discontinue it. Benzodiazepine use in elderly is very common in the current medical practice and it can cause significant side effects. To treat anxiety in elderly, each case needs to be thoroughly assessed in different aspects, such as psychological, neurocognitive, medical, and social. In our case, we were able to reduce the dose of benzodiazepine successfully using diverse treatment modalities, including alternative medication, supportive psychotherapy, psychoeducation, and utilizing reward system.

No. 161

Falling on Deaf Ears: A Case of Functional Hearing Loss in Outpatient Psychiatric Treatment

Poster Presenter: Ruby H. Barghini, M.D.
Co-Author: Aurelia Nicoletta Bizamcer, M.D., Ph.D., M.P.H.

SUMMARY:

Mrs. A., a 55 year-old Caucasian nurse with history of depression, presented to our outpatient psychiatric clinic on referral from ENT. The patient had experienced an acute onset of hearing loss after a viral upper respiratory infection and an unintentional overdose of her pain medication. Thorough otolaryngologic investigation revealed a discrepancy between the subjective and objective evidence for hearing loss. Mrs. A. was presumed to be suffering from a functional hearing loss and referred to psychiatry for further management. Her psychiatric evaluation revealed several psychosocial contributors to the development of her condition. The literature is sparse regarding psychiatric case studies and management of functional hearing loss. We have chosen to apply characteristics from the general management of psychosomatic patients. Treatment sessions are conducted via an audio

translator application on the patient's cell phone. Mrs. A has been engaged in her weekly therapy sessions in conjunction with medication management of her depressive and anxious symptoms with sertraline. Treatment goals include the resolution of conflict and grief from multiple losses, including her hearing and sense of control, and resumption of meaningful employment. In this poster, we will present a review of the literature regarding the etiology and treatment of functional hearing loss and create a psychodynamic formulation of the case.

Urophagia as Pica in a Patient With Schizophrenia

Poster Presenter: Eduardo J. Rodriguez-Perez, M.D.

SUMMARY:

INTRODUCTION The drinking of urine by humans has existed in several forms for centuries. Here we discuss the case of a patient with Schizophrenia who recounted his peculiar habits of drinking his own urine. We then discuss the possible diagnoses that can be considered in patients with this behavior, including pica and undinism. This is followed by a review of historical trials of urea therapy, and the exploration of socio-cultural and spiritual associations with urine consumption. CASE Patient was a 28 year-old man, with Schizophrenia and a history of substance use, on AOT, followed by ACT, admitted to inpatient psychiatry for aggressive behavior in the context of medication non-adherence. After stabilization of aggression, patient began discussing his ritualistic consumption of his own urine. He described that the idea came to him "in a spirit" and that his "body started calling for it." He reported consuming 8 ounces of his own urine daily, after "treating it" with herbs and baking soda to "get rid of microbes." He believes that drinking his own urine cures various ailments, including pain, nasal congestion. While he denied drinking urine during his admission, he planned on resuming urine consumption, which he believes will help him stop taking his psychiatric medication in the future. DISCUSSION There is little evidence on the prevalence of urine consumption, predominantly taking the form of case reports. Some authors have investigated the potential dangers of urine consumption, particularly to the exposure to drug-resistant bacteria, with some evidence of potential effects on the liver and kidneys. Urea therapy has been investigated in the past, specifically in relation to the treatment of cancer, but was found ineffective. Urine consumption is additionally a component of various cultures and religious sects dating back over 5,000 years. It has been used as traditional medical diagnosis and treatment before the age of modern medicine. And some positive associations have been seen in animal studies recycling urine under certain situations. The differential diagnoses of urophagia includes pica, which is the consumption of non-nutritional items, and undinism, which comprises several different fetishes involving urine. Some authors suggest disordered eating has a higher prevalence in patients with psychiatric disorders, and should be screened for more consistently. CONCLUSIONS Here we discussed the case of a 28 year-old man with Schizophrenia, who discussed an intricate ritual of consuming his own urine. The patient's presentation is most consistent with a DSM 5 diagnosis of pica. There was no indication in this patient that urophagia served an erotic or sexual function, nor did he identify a religious context to the behavior. While there is mixed evidence about the potential risks of urine, there is a potential benefit of screening patients with Schizophrenia for eating disorders.

Group Psychotherapy: Depression and Anxiety Education Group

Poster Presenter: Anthony Kelada, M.D.

SUMMARY:

Based on previous studies suggesting that a psychoeducational group can help patients comply with treatment for depression, we established a group in an outpatient setting which focuses on educating patients about depressive and anxiety symptoms, causes, treatment and the importance of compliance. This outpatient group was adapted from ana similar depression group that was developed for the hospital's inpatient unit. The original inpatient group initially began as a resident run quality improvement project with aims of helping hospitalized psychiatric patients learn more about treatment and management of depression and

follow up with outpatient caret. Positive feedback from patients who attended the inpatient group showed that patients liked the information and discussion aspect of the developed topics. This outpatient group has two leaders, a third-year psychiatry resident and a psychology intern. It consists of 9 one hour sessions. Two sessions focus on depression, two on anxiety, one on sleep hygiene, one on psychological factors of taking medication, one on grounding techniques, one on symptoms and how they may affect interpersonal relationships, and the final session on symptoms and how they can be addressed using cognitive behavioral therapy. Once all the sessions have been completed, it begins again from session number one. Patients who are enrolled in the clinic are welcome to begin attending the sessions at any point in the group. This outpatient group is an integration of psychoeducational and group processing, allowing patients to say whatever comes to mind yet providing the leaders with outlines to redirect the group when necessary. It is meant to be an adjunct treatment to the individual psychotherapy and pharmacological care that they are already being provided in the clinic.

Symbology in Frida Kahlo's Work

Poster Presenter: Beatriz Quintanilla Madero, M.D.

SUMMARY:

Introduction Frida Kahlo (1907-1954), a famous Mexican 20th Century visual artist, reflected her own life and suffering in her paintings. She has become an icon for many people, and her work has been endlessly reproduced in all kind of materials, even in pins, t-shirts, bags and other objects. She used direct and understandable visual symbols, which allow people to connect easily and emphatically with her message, her suffering and her anguish, even if they do not know anything about her life. She was married to Diego Rivera, a famous Mexican painter. Objective: To understand her illness through the symbology used in her work. Material and Method Four major Frida Kahlo's paintings: "Miscarriage", "Tree of Hope", "Broken Column" and "The Accident", are analyzed under a psychopathological point of view. Results: Many symbols of suffering, pain and illness are represented, such as broken leg, broken spine, tears, blood, a fetus and an abortion, nails piercing all her body. The viewer can understand the nature of the event the painter has drawn, and how she was psychologically affected. Symbols of anguish, pain, loss, distress and misery are found, along with sadness, depression and self-pity. Symbology used is direct and simple. Suffering is expressed in a very vivid way. All symbols are self-referenced. Narcissistic elaboration is found in a neurotic fashion. There are no signs of psychotic thoughts, neither psychotic symbology. Discussion and Conclusion Symbology of psychological suffering and pain are represented in a direct form in an expressive style. The author tries to make clear the nature of her pain and feelings and how important these events are in her life. Expressing these events through her paintings might have had a cathartic effect that helped her to cope with suffering and as a way to make others understand how she felt. These characteristics have make her to be well known and loved by millions of people around the world. And to become an icon for millions of people

No. 165

Comorbidity of Depression and Anxiety Disorders and Cystic Fibrosis: A Retrospective Data Analysis

Poster Presenter: Colleen McGavin Leitner, M.D.
Co-Author: Vishal Madaan, M.D.

SUMMARY:

Title: Impact of depressive and anxiety symptomatology in individuals with Cystic Fibrosis: A 15-year retrospective data review study Authors: Colleen Leitner, MD, Monica Periasamy, MPh and Vishal Madaan, MD Introduction: Cystic fibrosis (CF) is one of the most common genetic disorders in the Caucasian population, with conservative estimates at around 100,000 patients worldwide. A large international study recently found elevated rates of both depression and anxiety in individuals with cystic fibrosis (CF) compared with healthy individuals. Elevated symptoms of depression were reported in 10% of adolescents and 19% of adults, while elevated anxiety symptoms were found in 22% of adolescents and 32% of adults. Research also suggests that depression and anxiety in CF may be associated with worsening lung function. Several recent studies have also linked depression in CF with poor treatment adherence as well as longer hospital stays and increased healthcare utilization. Objective:

The study was conducted to review de-identified data of individuals with CF over 15 years to examine the prevalence of depression and anxiety in our patient population. In addition, the investigators looked at the data to determine if depression and anxiety led to increased healthcare utilization and served as moderators for other factors such as frequency of inpatient visits and duration of hospitalization. Methods: De-identified data was collected from the University of Virginia's Clinical Data Repository (CDR). The CDR is a database that has collected clinical data based on billing codes. Parameters included patients with a diagnosis of CF from the years 1992-2016 seen on an inpatient and outpatient basis. A subset of patients with diagnoses of depressive or anxiety disorders was compared to the entire CF population in terms of their impact on several available parameters. Results: Of the 1375 CF patients, 145 (10.5%) CF patients had documented diagnoses of anxiety or depression. These patients had more frequent inpatient visits, longer hospital lengths of stay, and higher overall hospital cost than the CF patients without depression or anxiety diagnoses . The data points to a need for regular screening for anxiety and depression symptoms in the CF population in order to optimize patient outcomes as well as minimize healthcare costs.

Central Serous Chorioretinopathy and MDD: Is There a Link?

Poster Presenter: Aamani Chava, M.D.
Co-Authors: Zohaib Majid, Shabber Agha Abbas, Asghar Hossain, M.D.

SUMMARY:

Introduction: Central serous chorioretinopathy (CSC) is an idiopathic disease affecting mostly Caucasian men between the ages of 20-50. It is characterized by serous detachment of the retina in the macular region of the eye due to a focal retinal pigment epithelial defect. Patients typically complain of blurred vision, central scotoma, micropsia, or metamorphopsia. Apart from medical risk factors, impulsivity, overachievement, emotional instability, psychological stressors, and use of psychopharmacologic agents have each been identified as potential risk factors. Objective: The objective of this article is to report a case of new-onset major depressive disorder with psychotic features in a 48-year-old patient with a recent diagnosis of CSC. Case: 48-year-old Caucasian male with no documented past psychiatric history or hospitalization was brought to Bergen Regional Medical Center by EMS for psychiatric evaluation after he made suicidal threats that were reported by his wife. According to her, his symptoms began three weeks ago when he was diagnosed with CSC and gradually worsened thereafter. Prior to the diagnosis he had been very concerned about his failing business and regarding a recent home purchase he had made. Over the duration, he became more isolative and withdrawn, often locking himself in his office while perseverating about the three stressors. Few days prior, he reportedly was isolated, detached, and was endorsing depressive symptoms of avolition, anhedonia, poor concentration, insomnia, decreased appetite, and self-injurious behavior. Since then he reportedly began exhibiting worsening depressive symptoms and disorganized behavior. Most recently, he was observed sitting in the dark only responding to internal stimuli, was not responding to verbal redirection, and was making verbally aggressive statements. In the emergency department he was started on sertraline 50 mg qd and was admitted for observation. Discussion: Review of available literature has indicated that psychosocial stressors either trigger CSC, are an important risk factor for its development, or perhaps both. The association of CSC with type A personality individuals is also observed. Psychosomatic complaints, unfavorable stress coping strategies, and elevated tension, aggression, emotional instability, and achievement orientation have all been identified as potential precursors. Many of these psychiatric difficulties were present in our patient prior to his onset of CSC. It would be interesting to know whether there exists a causal relationship between psychiatric precursors and the development of CSC or do psychiatric symptoms represent a manifestation of CSC pathology or is there a larger syndrome that is definable. Conclusion: Further research is required to explore the potential relationship between CSC onset and the development of new-onset psychiatric symptoms. Our case report may serve as preliminary evidence for such a correlation.

No. 167

VNS-Associated Psychosis: A Case Report

Poster Presenter: Aamani Chava, M.D.
Co-Authors: Naveed Butt, Asghar Hossain, M.D.

SUMMARY:

Introduction: Epilepsy is most commonly treated with antiepileptic drugs however, 30% of patients do not respond to adequate pharmacological treatment and are considered refractory (Kwan, Brodie, 2000). Vagus nerve stimulation (VNS) is a neurophysiological treatment for refractory patients and is designed to prevent seizures by sending regular, mild pulses of electrical energy to the brain via the vagus nerve. Case Report: We present a case of a 54-year-old male who came to the emergency room with disorganized behavior, paranoid persecutory delusions, and hallucinations. The patient had a history of seizure disorder secondary to a TBI. His seizures were well controlled with vagus nerve stimulation device but recently he underwent battery replacement and device was calibrated to control his increased frequency of seizures. He developed psychosis afterwards. Discussion: VNS is most commonly achieved by surgical implantation of a stimulating, current-carrying wire around the vagus nerve in the left side of neck. The wire is intermittently stimulated by a battery-operated generator that is implanted in the left chest wall under the skin. The device is set to give stimulation at regular intervals during the day, usually with 30 seconds of stimulation alternating with 5 minutes of no stimulation. Settings also called stimulation parameters can be adjusted by the neurologist to control the patient seizures. Clinicians need to be aware of the paradoxical possibility that normalization of EEG and reduction of seizure activity may be followed by the appearance or exacerbation of psychosis. It is estimated that 7–10% of patients with seizure disorders suffer from psychotic symptoms. The psychotic symptoms commonly reported are hallucinations, delusions, and prolonged euphoric states. It was observed that some of these symptoms tend to occur after marked reduction in seizure frequency and normalization of the electroencephalograph. Although many studies reported increased alertness and reduced sedation after VNS but there are case reports demonstrating the induction of psychotic symptoms following seizure control with VNS. Veerle de herdt et al,(1) presented a case series to study the emergence of psychotic symptoms after treatment with VNS for epilepsy. Their study described four patients who were treated with VNS after failure of response to antiepileptic drugs and were subsequently treated with VNS. During the ramping-up procedure of the output current, all four of these patients presented with psychotic symptoms. Conclusion: Further investigation and observation will be needed to establish the underlying mechanisms of these psychotic symptoms during VNS and to investigate which patients may be specifically sensitive for the development of such conditions.

Psychiatric Comorbidities and Related Outcomes in Epilepsy Patients: An Insight From Nationwide Inpatient Analysis in the United States

Poster Presenter: Rikinkumar Patel
Co-Authors: Ahmed Z. Elmaadawi, M.D., Zeeshan Mansuri, Mandeep Kaur, Kaushal Shah, Suhayl Joseph Nasr, M.D.

SUMMARY:

Background: Psychiatric disorders are frequently encountered in patients with epilepsy. These may negatively influence the course of epilepsy. To the best of our knowledge this is the first study to report the impact of various psychiatric comorbidities in Epilepsy patients regarding hospitalization outcome. Methods: We used the Nationwide Inpatient Sample (NIS) from the Healthcare Cost and Utilization Project (HCUP) for the years 2013-2014. We identified Epilepsy as the primary diagnosis and used AHRQ comorbidity software to generate binary variables that identify the following psychiatric comorbidities: alcohol abuse, depression, drug abuse and psychosis using validated ICD-9-CM codes. Pearson's chi-square test and independent sample T-test were used for categorical data and continuous data, respectively. Differences in comorbidities were quantified using Chi-Square tests. Multinomial logistic regression model was used to quantify associations among comorbidities and inpatient mortality, length of stay and inpatient charge (adjusted Odds Ratio (aOR)). Discharge weights were applied in all regression models, and all estimates

were adjusted for age, gender, race, and median income of the patient's zip code, hospital bed size, and location, region and teaching status. All statistical analyses were done using SPSS 22. Results: The sample consisted of 397,440 hospitalizations for Epilepsy. The mean length of stay was 3.83 days and the mean total charge was $35,973.70. The in-hospital mortality rate was 0.7%. Psychiatric comorbidities were identified in 39.9% of inpatients with epilepsy including 13% with depression, 10.4% with psychosis followed by alcohol abuse (8.7%) and drug abuse (7.8%) Relative to the other psychiatric comorbidities, the risk of inpatient death was only seen in Epilepsy patients who had comorbid alcohol abuse (aOR 1.164; p = 0.007). Also compared to the other comorbidities, depression was associated with a higher risk of length of stay of more than 3 days (aOR 1.473; p <0.001) and higher total charge of >$21,000 (aOR 1.242; p<0.001), followed by psychosis (aOR 1.290; p<0.001) and higher inpatient cost of care (aOR 1.071; p<0.001). Comorbid drug abuse did not have an increased risk of the length of stay of more than three days (aOR 0.833; p<0.001). Comorbid alcohol abuse did not have an increased risk of inpatient total charge > $21,000 (aOR 0.926; p<0.001). Conclusion: In a large sample of hospitalizations for Epilepsy, four psychiatric comorbidities were associated with significant differences in the risk of death, length-of-stay, and inpatient total cost. Early diagnosis and treatment of comorbid psychopathology can save lives, lower length of hospital stay and subsequently the cost of care.

No. 169

Impact of Depression on Hospitalization and Related Outcomes for Parkinson's Disease: A Nationwide Inpatient Sample-Based Retrospective Study

Poster Presenter: Rikinkumar Patel
Co-Authors: Amit Chopra, M.D., Ramkrishna D. Makani, M.D., M.P.H., Zeeshan Mansuri, Upenkumar Patel, M.B.B.S., M.P.H., Rupak Desai, M.B.B.S.

SUMMARY:

Background: Major Depressive Disorder (MDD) is a common comorbidity in Parkinson's disease (PD) and it significantly affects the quality of life and disease outcomes in PD patients. Previous studies were done to measure prevalence, neurobiology, and impact on health related quality of life in PD patients with depression. No studies have been conducted to our knowledge to address the health care utilization and its outcomes in PD patients with MDD. This study analyzes and discerns the differences in the hospitalization outcomes, comorbidities, and utilization of procedures in PD patients versus PD patients with MDD. Methods: We used the Nationwide Inpatient Sample (NIS) from the Healthcare Cost and Utilization Project (HCUP) from year's 2010-2014. We identified PD and MDD as a primary and secondary diagnosis respectively using validated International Classification of Diseases, 9th Revision, and Clinical Modification (ICD-9-CM) codes. Pearson's chi-square test and independent sample T-test were used for categorical data and continuous data. All statistical analysis was done by SPSS 22.0 in this study. Results: Extensive analysis was performed on 63,912 patients with PD and 1445 patients with PD having MDD. PD with MDD patients had three times greater chances of disposition to acute care hospital (3.1% vs. 1.1%, p<0.001). Median length of hospitalization was higher in PD with MDD patients (5.85 vs. 4.08 days; p<0.001) though the median cost of hospitalization was low ($31,039 vs. $39,464; p <0.001). Utilization of Therapeutic Nervous system procedure was lower in PD with MDD patients (29.9% vs. 59.5%; p<0.001). Diagnostic procedures like CT-scan, MRI and diagnostic spinal tap were performed more in PD with MDD patients (5.5%, 6.6% and 3.4% respectively) compared to PD patients (4.2%, 2.8% and 2.5% respectively)(p-value<0.001). Utilization of Deep Brain Stimulation was lower in PD patients with MDD (9.4% vs. 25.6%, p<0.001). PD with MDD patients had about twice greater risk of major or extreme loss of function as compared to PD patients due to which they were at greater probability of dying (p<0.001). In-hospital mortality was significantly higher in PD patients with MDD (1.4% vs. 1.1%; p<0.001). Comorbidities present in PD with MDD patients are Alcohol Abuse (3.7%), Psychosis (100%) and Drug Abuse (5%) compared to 1.4%, 0 %, and 0.8% respectively in PD patients (p-value<0.001). Conclusion: Our study establishes the negative impact of depression in PD in terms of hospitalization related outcomes including the illness severity, comorbid conditions, risk of mortality, utilization of diagnostic and

therapeutic procedures, length of stay and disposition as compared to PD alone. Further research to guide development of clinical care models for targeting identification and treatment of depression in PD are warranted to both reduce mortality and morbidity and improve quality of care in PD with MDD.

No. 170

Investigating the Association Between Inflammation and Depression

Poster Presenter: Anjali Thakrar, M.D.

SUMMARY:

Background: Depression is the leading cause of morbidity worldwide. A significant number of patients remain refractory to current treatment modalities. Therefore, it is pertinent to further understand the pathophysiology of depression and additional clinical correlates in order to investigate additional treatment modalities. Several studies have suggested that inflammation plays a role in the pathogenesis of depression. The aim of this paper is to further elucidate the association between inflammatory markers and depression. Methods: A literature review was conducted using a combination of key terms “depression”, “inflammation”, “cytokines”, “prostaglandins”, and “interleukins”. Results: Rates of depression have been shown to be higher in patients with chronic inflammatory disorders compared to the general population. Several studies have found that depressed patients have elevated serum inflammatory cytokine levels, which are correlated with depression severity. Other studies have demonstrated that administration of cytokines produces depressive symptoms. Furthermore, anti-depressive treatments have been shown to reduce serum cytokine levels. Conversely, anti-inflammatory agents may have anti-depressive effects. Conclusion: Inflammation is correlated with depression. Further studying this association along with the temporal association may help elucidate the framework for novel treatment options.

No. 171

Delirious Mania in a Geriatric Patient

Poster Presenter: Anjali Thakrar, M.D.

SUMMARY:

Delirious mania (DM) is a potentially fatal neuropsychiatric syndrome of unknown etiology, often characterized by the acute onset of delirium, symptoms of mania, and psychosis. The presentation is often punctuated by catatonia. DM is estimated to occur in 15-20% of patients with bipolar disorder specifically during episodes of mania. Despite being a relatively common entity, literature is sparse and there are no formal diagnostic criteria or treatment guidelines. We report a case of a 71-year-old patient with a previous diagnosis of bipolar disorder. At the baseline, the patient was fully oriented and independent with activities of daily living. The patient presented with acute onset of worsening confusion, insomnia, increased goal directed behavior, impulsivity, agitation, and bizarre delusions. Initial investigations, including UA, CT head, CBC, and BMP returned normal. Given the presentation with symptoms of mania, psychosis and fluctuating sensorium, the patient was diagnosed with DM. ECT was considered, however, family declined. The patient was treated with a combination of valproic acid, olanzapine, and lorazepam. Symptoms improved on this regimen and the patient was discharged 26 days after admission. This was her second episode of DM, suggesting that some patients may be at risk for recurrent episodes. ECT is considered to be the definitive treatment for DM. Lorazepam has also demonstrated efficacy. Our patient responded to moderate doses of lorazepam, valproic acid and olanzapine, however, recovery from the acute episode was protracted. Early diagnosis and aggressive treatment may be essential to reduce the morbidity and mortality associated with DM.

No. 172

Management of Acute Mania in a Peripartum Patient

Poster Presenter: Bao M. Vo, D.O.

SUMMARY:

Mrs. A is a 35-year-old G2P1001 woman at 37w3d of pregnancy with past psychiatric history of Bipolar I Disorder, who presented to the psychiatric consult service with aggressive behaviors, throwing her body around with no regard for her unborn child and requiring restraint with handcuffs. She was actively psychotic, speaking to her daughter who was not

present during her initial interview. She has a history of eight manic episodes occurring annually, each of which required hospital admission before achieving stabilization seven years ago. However, she stopped taking all her medications when she learned she was pregnant. There were no complications with the pregnancy initially, but in the week before her hospital presentation, she developed insomnia, sporadic eating habit, inadequate fluid intake, and hyper verbality with rapid speech. Complicating her history was a prior cesarean delivery for failed induction of labor, as well as previous post-partum depression. The obstetrics service was consulted before her transfer to the psychiatric floor. She was deemed to have a maximum of two and one-half weeks until her delivery via cesarean section. Before and during her acute episode of mania, she expressed the wish to attempt a normal vaginal delivery. She required a team of psychiatrists, obstetricians, anesthesiologists, ethicists, as well as a strong supporting medical cast. Her case presents multiple challenges involving the capacity to make medical decisions, management of acute mania during late stage pregnancy, and ultimately securing the health of the patient and her child.

No. 173

Fear as a Manic Trigger: A Case Report

Poster Presenter: Becky Wu, M.D.

SUMMARY:

The patient is a 23-year-old female who was involuntarily hospitalized on an acute inpatient psychiatric service with delusions, pressured speech, flight of ideas, religious preoccupation and lack of need for sleep. She was in an acute manic state with psychosis. She was started on valproic acid for mania, aripiprazole for psychosis, and lorazepam for agitation. The patient stabilized on valproic acid (total of 750 mg/day, level 86) and aripiprazole (20 mg/day). She became more coherent; her speech was less pressured; and she was not articulating delusions. Given the improvement, discharge was planned. Aripiprazole long-acting injectable was discussed with the patient. She expressed fearfulness about the injection, but she reluctantly accepted it nonetheless. Within 24 hours of receiving the injection, the patient decompensated. Manic and psychotic symptoms recurred and led to a prolonged hospital course. In an effort to control these symptoms, the medication regimen was changed to haloperidol, lithium and lorazepam, all in liquid form. Gradually, the patient again improved. She accepted haloperidol decanoate and was stable at discharge. In this poster, we discuss triggers of mania as well as dysregulations in neural circuits as possible predisposing vulnerabilities to an acute episode. To our knowledge, this is the first case of fear as a trigger of mania in a hospitalized patient.

No. 174

Is There a Correlation Between Urinary Tract Infections and Manic Episodes? A Literature Review

Poster Presenter: Brent Jakubec, M.D.

SUMMARY:

Background: Urinary Tract Infections (UTIs) are among the leading reasons for treatment in adult primary care medicine, and are accountable for a considerable percentage of antibiotic prescriptions. The lifetime prevalence of Bipolar Disorder (BD) is 1% in the United States (US), and the 18th leading cause of disability. The purpose of this paper is to review current literature on UTIs, and their association with manic episodes in individuals with an established diagnosis of BD. Methods: A literature review using, but not limited to, the following key terms “UTI Mania; Infection Bipolar Disorder”. DSM5 Criteria were used in defining a manic episode. UTI was defined as a dipstick urinalysis positive for leukocyte esterase, ? 5–10 leukocytes on urine microscopy, and/or nitrates. Results: Searches yielded 1,216 articles, of which 13 were chosen. Selection criteria was based on relevance of the article to affective or psychotic symptoms in the setting of a UTI. Discussion: Although mania is commonly associated with Bipolar Disorder (BD), it can have many other non-psychiatric etiologies. Inflammation and maternal or fetal infections have been suggested as risk factors for schizophrenia (SZ) and BP, as well as for suicide. One study showed that any history of hospitalization for infection increased the risk of later mood disorders by 62%, and that a prior hospital contact, because of autoimmune disease, increased the risk of a subsequent mood disorder diagnosis by 45%, demonstrating that the number of infections and autoimmune diseases increases the risk of mood disorders in an exposure

response relationship. In addition, patients requiring hospitalization for an infection, had an increased risk of death by suicide. Exposure to physical or psychologic stressors is known to increase the risk of acquiring infections, and enhances immune responses. Patients may report episodes of stress preceding the development of mood disorders, and the inflammatory response might simply be a parallel finding, and not just a causal relationship. The clinical course of a neuropsychiatric disorder may be precipitated or exacerbated by a UTI. Conclusion: In examining the question on whether there is a correlation between UTIs and mania or not, this literature review, at least, suggests that the clinical course of a neuropsychiatric disorder may be precipitated or exacerbated by a UTI. Other recent research has shown that there is a link between the development of mood disorders and inflammation, along with elevated CRP levels in patients with BD, as well as an increased risk of suicide in patient hospitalized for infections. Combination therapy of psychotropic medications and antimicrobials, in this clinical picture, likely improves symptoms. However, treatment with select antimicrobials has an increased risk of developing mania.

No. 175

Divalproex and Lithium Combination Treatment in Bipolar Disorder

Poster Presenter: Chandan Samra
Co-Author: Sarayu Vasan, M.D., M.P.H.

SUMMARY:
Background: Bipolar is a common mood disorder characterized by episodes of mania, depression, or mixed symptoms. Manic symptoms include distractibility, grandiosity, flights of ideas, racing thoughts, increased goal directed activity, decreased need for sleep, excessive talking or pressured speech, and increased sexual desire. Depressive symptoms in bipolar disorder include sad mood or anhedonia with decreased energy, lack of focus and concentration, overwhelming guilt, hopelessness and suicidal ideations. The treatment for bipolar disorders has been extensively researched over the years, revealing mood stabilizers such as lithium and divalproex and atypical antipsychotics to be the most effective. The combined use of a mood stabilizer along with an atypical antipsychotic is a common practice whereas the use of two mood stabilizers is infrequent. The role of any medication is to reduce symptoms, prevent relapses and recurrences, and provide long term stability. However, in this literature review, we look at the possible benefits such as a decrease in relapse and increase in remission by using the combination of lithium and divalproex. Methods: A literature search was performed using PubMed and Google Scholar. The search was completed by using the following medical subject headings and their derivatives: “lithium,” “Depakote,” ‘divalproex,” “combination of lithium and divalproex,” “mania treatment,” “benefits of lithium and divalproex,” “lithium and divalproex versus atypical antipsychotics.” We limited our search to human subjects. Results: A few studies have been conducted that suggest the benefits of combined usage of lithium and divalproex. Although, the study samples were small, many of these studies concluded that patients on the combined regimen had a decrease in relapse or recurrence when compared to lithium monotherapy. The combination use has shown to be quite effective in patients with rapid cycling bipolar disorder. Conclusion: The treatment of bipolar can prove to be challenging when the patient is not responding to monotherapy or the combined use of a mood stabilizer and an atypical antipsychotic. In such cases, the use of two mood stabilizers would prove to be beneficial. However, there are limited controlled studies done exploring the combined use of two mood stabilizers thus many clinicians abstain from using this combination. We believe this combination treatment needs to be utilized in daily practice by clinicians. In order to do so, we strongly suggest the importance of conducting research in regards to using this combination of valproate and lithium by using larger study samples and a widespread population of patients with bipolar disorder. Thorough research on this combination can prove to be very efficient in treating bipolar disorders.

No. 176

Determining the Cutoff for the Definition of Early Improvement to Predict Stable Response: A Retrospective Chart Review Study

Poster Presenter: Lee Eunsaem, M.D.

SUMMARY:

Determining the cut-off for the definition of early improvement to predict stable response: A retrospective chart review study Eun Saem Lee, MD, Hee Ryung Wang, MD, PhD, Woo Young Sup, MD, PhD, Tae Youn Jun, MD, PhD and Won Myong Bahk, MD, PhD* Objectives: This study aims to investigate whether early improvement commonly defined as 20% or more reduction of depressive symptoms after 2 weeks of pharmacotherapy could predict stable response after 4 weeks among patients with major depressive disorder (MDD). We also investigate which definition of early improvement could predict stable response most accurately. Methods: We retrospectively reviewed the medical chart records of 64 patients with MDD. Initially, we performed logistic regression analysis to investigate whether early improvement predicts stable response after 4 weeks. Further, we performed comparison of ROC curves with differing definitions of early response. Results: Early improvement defined by 20% or more reduction of 17-item Hamilton Depression Rating Scale (HAMD-17) at week 2 was significantly associated with stable response after week 4 (OR=4.451, p=0.042). Comparison of ROC curves according to differing definitions showed that early improvement defined as 15% or more reduction of HAMD-17 score at week 2 predict stable response after week 4 most accurately with sensitivity of 92.7% and specificity of 39.1% (AUC= 0.659, p=0.036). Conclusion: This study showed that early improvement defined as 15% or more reduction of HAMD-17 at week 2 could be used adequately as a predictor for future treatment response among patients with MDD.

Neo Neuro-Chemical Dance: Bipolar Disorder I With Psychotic Features S/P VP Shunt

Poster Presenter: Harjasleen Bhullar Yadav, M.B.B.S. Co-Authors: Seema Hashmi, Jacob Elliott Sperber, M.D., Leena Mohan, M.D.

SUMMARY:

Case Presentation: 31 years old racially diverse female was referred to psychiatry for evaluation of psychosis and aggressive behavior. She had extensive comorbidities hydrocephalus gout, prediabetes, migraines, polycystic ovary syndrome, with past psych history of Anxiety, panic disorder by self report, no prior psychiatric contact, no significant substance use history, history of being raped when young (declined to elaborate further), family history of dementia. Patient had meningitis and ventriculitis, which resulted in hydrocephalus in 2014. She was initially managed with endoscopic third ventriculostomy. With no much improvement in symptoms she needed posterior fossa exploration and external ventricular drain placement and later VP shunt was placed in March 2015. Patient had VP shunt malfunction needing repeat VP shunt June 2015. While undergoing physical therapy for gait imbalance, inability to perform ADLs after surgery, she began to experience delusional episodes, auditory hallucinations in addition to exhibiting aggressive behavior. She reported hearing voices of her grandmother along with other males and females (non command type) mostly telling her to take it easy, and also believed that grandmother visited her in the hospital while no one was there. During this period, she reported increased energy, irritable mood; poor sleep, racing of thoughts. Mother of the patient being the health proxy provided most of the collateral information. Her mother described her as “Y” during the episodes of agitation and aggression referring to her other side of the personality. Mother did not confirm any prior psychiatric history. She reported history of bullying in school from 5th to 8th grade. She described herself as an anxious kid with worsening of anxiety symptoms due to her medical condition. She also reported history of episodes of panic attacks with unclear trigger, where she felt chest discomfort, palpitations, sweating but was able to relax with deep breathing exercises. Both patient and her mother reported she had some episodes of mood instability, aggression and irritability with onset s/p neurosurgeries, which was not the normal. Suicidal/ homicidal risk assessment performed. Strongly denied any suicidal, homicidal ideations, intent or plan during the interview. She denied any PTSD symptoms, OCD symptoms. She also denied any episodes of psychosis / mania in the past. She reports having memory loss and decline in cognition s/p neurosurgeries. During evaluation, MMSE was done, she scored - 23 /30, MOCA was completed X scored - 20/30. She was initially started on Valproic acid 250 mg two times a day, in addition to

Aripiprazole 5 mg once daily. Depakote had to be stopped because of excessive weight gain, and Aripiprazole was titrated up to 7.5 mg once daily to which the patient responded well, with good tolerability and no reported side effects.

No. 178

A Visual Time Perception Task From Manic to Depressed Mood in Bipolar Patients

Poster Presenter: Inki Sohn
Co-Author: Beomwoo Nam

SUMMARY:

Objectives: Time reproduction is shorter in acute manic mood than in euthymic mood is already reported by us. But it is not studied that time reproduction change from acute manic mood to depressed mood. The purpose of this study was to investigate relationship mood state with time reproduction in patients with bipolar disorder. Methods : 30 patients with bipolar I disorder(acute manic) were included. They were presented with a time reproduction task at acute manic state and following 1st, 2nd, 3rd , 6th, 9th, and 12th month. Subjects were asked to observe a light bulb “on” and “off” on a portable computer screen for 1, 11, and 36 seconds. After that, they were asked to reproduce a same length of time of a light bulb “on” and “off. We evaluated Young Mania Rating Scale(YMRS), the Hamilton Depression Rating Scale(HDRS) and the Global Assessment Functioning(GAF) of the patients. Results : They reproduced 760.4±209.7msec in acute manic mood, 977.6±108.5 msec in euthymic mood, and 1092.2±147.2 msec in depressed mood in the case of 1 second stimuli($P>0.05$). They did 9802.3±1010.4 msec in manic mood, 11200.0±790.5 msec in euthymic mood and 12909.5±980.0 msec in depressed mood in the case of 11 seconds stimuli($P<0.05$). They did 32209.2±2039.8 msec in manic mood, 36799.3±2009.9 msec in euthymic mood and 39309.5±1991.7 msec in depressed mood in the case of 36 seconds stimuli($P<0.05$). The time reproduction in manic mood were correlated with YMRS score, and it in depressed mood were correlated with Hamilton Depression Rating score. Conclusions : Time reproduction becomes longer in acute manic mood, euthymic mood and depressed mood in ascending order. So it supports the hypothesis that mood symptom severity is correlated with time perception.

No. 179

Case Report: Gambling Disorder Treated With Abilify Maintena

Poster Presenter: Najeeb U. Hussain, M.D.
Co-Authors: Brian Chang, Juvaria Anjum

SUMMARY:

27-year-old male patient with no significant past psychiatric history who first presented with suicide attempt by choking himself with a belt and threatening to cut his wrists with a knife, had gotten heavily involved in online gambling since past one year and was involuntary admitted on psychiatry unit. To begin with he was involved in small bets then after several successful months, he began to make larger bets until a few weeks prior to his suicide attempt. Collateral history from his family reported that he had recent multiple stressors. His past behavior was noted for mood swings, depressed mood since the past year, racing thoughts, and poor impulse control including large spending sprees. The patient’s final diagnosis was bipolar disorder mixed type, for which we treated with Abilify Maintena and Depakote. He had been non-compliant with oral aripiprazole on the psychiatric floor. Our poster here will be discussing how Abilify Maintena (injection form) was chosen to treat this patient due to non-compliance with oral aripiprazole. As a partial D2 agonist, aripiprazole decreases overall dopaminergic activity of the mesolimbic pathway, decreasing his perception of reward and stabilizing his impulsive behavior.

No. 180

Amoxicillin/Clavulanic Acid-Induced Mania

Poster Presenter: John Azer, M.D.

SUMMARY:

B.V. is a 53 year old male with a past psychiatric history of major depressive disorder who presented to the emergency department for altered mental status. Prior to arrival, he presented to an outpatient cardiology clinic for routine follow-up. The patient was discovered by the staff to have incoherent and rapid speech, grandiose ideation, reporting to them that he had not slept in a 3 day period. When he

presented in the emergency department, he was discovered to have significant psychomotor agitation, noticeable distractibility, increased rate of speech, intense eye contact, an affect characterized primarily by irritability, and illogical and tangential thought processes. Differential diagnosis being considered at the time was hyperactive delirium, substance-induced mood disorder, or bipolar disorder. An organic work-up was preformed and was noted to only be remarkable for a urine drug screen that was positive for marijuana, a leukocytosis at 18,500 WBC/uL, and a chest x-ray that was remarkable for heterogeneous opacities in the right base. Mini-Mental State Examination was a 23/30. He was admitted to the general medicine service with a diagnosis of hyperactive delirium. Collateral obtained from his family during the hospitalization revealed the patient was treated for a sinus infection with amoxicillin-clavulanic acid 10 days prior to admission. The family reported a temporal relationship between the patient starting amoxicillin-clavulanic acid and the change in his behavior. This case highlights the presentational overlap between delirium and mania, the importance of obtaining collateral in cases of altered mental status, and a potential iatrogenic cause of mania.

No. 181

Acute Psychosis or Kundalini Awakening? Considering Cultural Factors in the Evaluation of Psychosis

Poster Presenter: John Azer, M.D.

SUMMARY:

Kundalini awakening is a complex physio-psychospiritual transformative process resulting from deep meditation. It has been described as being accompanied by a complex pattern of sensory, motor, mental, and affective symptoms. This is the case of a 22-year-old male with no past psychiatric or medical history who presented to the emergency department for evaluation of psychosis at the recommendation of an employee of the UVA Center of Perceptual Studies. Upon initial interview, the patient reported that he had traveled from New York City to Charlottesville to be investigated by the Center of Perceptual Studies. He presented with ideations concerning for psychosis, including a reported history of out of body experiences, an experience during meditation where he visualized a light enter through his tailbone and rectum and surge up through his body, and a belief that he was being sustained by an energy that did not allow him to sleep or eat for a few days. This was accompanied by a belief that he could control his autonomic nervous system, including his heart rate and his body temperature. His mental status examination on presentation was remarkable for increased rate of speech that was interruptible, euthymic to elevated affect, and a predominantly linear and logical thought process. His workup was unremarkable outside of a urine drug screen that was positive for marijuana. The differential diagnosis at that time included schizotypal personality disorder, a substance-induced illness, bipolar disorder with psychosis, or a primary thought disorder. Once admitted to the psychiatric unit, the patient displayed no other signs concerning for psychosis. After discussion with the UVA Perceptual Studies division, the patient's presentation was thought to be consistent with a Kundalini awakening. This case highlights the importance of considering culturally influenced experiences when evaluating for psychosis.

No. 182

Lithium-Induced Autoimmune Effects: A Case Report

Poster Presenter: Naveed Butt
Lead Author: Sheema Imran, M.D.
Co-Authors: Ali Raza, Asghar Hossain, M.D.

SUMMARY:

Objective: The objective of this article is to report immunologically induced side effects of lithium. Case Description: This is a case of 32-year-old female admitted to Bergen Regional Medical Center with disorganized behavior, elevated mood, irritability and auditory hallucinations after engaging in the excessive use of marijuana. She was discharged on Klonopin 0.5mg PO b.i.d, Prozac 20 mg PO daily, Neurontin 300mg PO t.i.d and Seroquel 50 mg PO at bed time. She was started on lithium in the outpatient clinic to address her mania. She later developed asymmetrical joint pains and fever for which she was referred to rheumatologist. Blood workup confirmed the presence of antinuclear

antibodies (ANA). It was decided to discontinue the lithium after searching through research articles to establish the association of lithium with autoimmune diseases like autoimmune thyroiditis and psoriasis. Patient got better afterwards and her joint pains resolved. Discussion: Lithium remains an imperative drug in the long-term therapy of bipolar affective disorders. It is also a proven prophylactic agent against relapses or recurrences of abnormal mood episodes in unipolar depression, hypomania and mania. It has also been shown to reduce suicidal risk and short term mortality. Despite its proven efficaciousness, its use is associated with numerous clinical limitations. These include: a narrow therapeutic window hence necessitating regular monitoring of therapeutic concentrations, cardiac toxicity, renal tubular dysfunction and endocrinopathies like thyroid abnormalities, hyperparathyroidism, transient hyperglycemia and nephrogenic diabetes insipidus. This review will focus mainly on the effects of lithium on the immune process. Probable autoimmune mechanisms include that lithium enhances the activity of B lymphocytes leading to increased IgG and IgM production, reduction of the ratio of circulating suppressor to cytotoxic T cells (Wilson et al. 1989; Kibirige et al. 2013) and its effect of inducing proin?ammatory cytokine production. The latter assumption is substantiated by studies which describe the role of IL-1ß (Paolieri et al. 1999), IL-6 (Simons et al. 1998) and TNF-a (Tarhan et al. 2013) in autoimmune thyroiditis. The activation of pro-in?ammatory cytokines by lithium may contribute to the intended therapeutic effect of dampening mood in manic patients, but may also cause some of the side effects of lithium, seen in patients suffering from certain autoimmune diseases such as autoimmune thyroiditis and psoriasis. Conclusion: In conclusion, we found that lithium activates the production of cytokines that promote in?ammatory processes such as IL-1ß, IL-2, IL-6, IL-17 and TNF-a which might contribute to the therapeutic effects, but also the autoimmune side effects of lithium.

No. 183

Cocaine-Induced Chorea: A Case Report

Poster Presenter: Naveed Butt
Lead Author: Tarek Aly, M.D.
Co-Authors: Juan S. Pimentel, M.D., Asghar Hossain, M.D.

SUMMARY:
Chorea is derived from the Greek word meaning" choral dance". It is characterized as brief, asymmetrical, irregular, non-repetitive and non-rhythmic spontaneous movements which may vary from restlessness, mild fidgeting and dance like gait to continuous flow of disabling violent movements. Among the other causes of chorea which include hereditary, metabolic and infections, cocaine and amphetamines are one of those. In this abstract, we would like to focus on complex relation between chorea and cocaine abuse. We are presenting a case of 30 y/o female with history of cocaine use who presented at Bergen Regional Medical Center with movement disorder: chorea. Patient and collateral reported patient developed it after ingesting unspecified amount of crack cocaine. Cocaine was confirmed in urine and the quantitative value was >5400.0 ng/ml. Cocaine use remains a significant problem worldwide, with an estimated 18.2 million users between age 15 to 64 years. Its use is more prevalent in North America with 5.1 million users. It blocks the dopamine transporter(DAT) and prevents the reuptake of dopamine and other catecholamines at presynaptic terminal. By this way, it increases the concentration of dopamine at extracellular levels which exerts all its euphoric effects as well as motor effects. Although movement disorders may develop primarily due to neurologic disease but it may be a manifestation of certain medication abuse or withdrawal. Abuse of psychostimulants like cocaine may cause numerous movement disorders through their interaction with different neurotransmitter systems, including dopaminergic, noradrenergic, serotonergic, and GABAergic systems. Movement disorders can be either hyperkinetic or hypokinetic including parkinsonism, tremor, dyskinesia, and myoclonus. Most of these disorders are either directly or indirectly related to the basal ganglia of the brain. Hyperkinetic disorders include tics, dystonia, myoclonus and akathisia. One of the dramatic movement disorder caused by cocaine is the chorea and akathisia commonly known as “crack dancing” and buccolingual dyskinesia known as twisted mouth. This disorder is more prevalent among younger cocaine users but it is hard to assess the overall prevalence of chorea in cocaine users as

the disorder is mostly self-limited and under reported. We concluded that increase in choreo-athetoid movement in a patient with substance use disorder may be related to cocaine use.

No. 184

Spiritually Integrated Psychiatric Care in an Urban Setting

Poster Presenter: Mena Mirhom, M.D.

SUMMARY:

Background: One in four patients who seek mental health care will first seek treatment from their clergy member. While this figure has declined over the recent decades, clergy continue to be contacted at a more frequent rate than psychiatrists or general medical doctors for initial mental health care. (1) With this in mind, we began a study in our hospital to determine how residents and patients perceive the role of spirituality in psychiatry. We seek to identify benefits and barriers of integrating spirituality into psychiatric care. Based on the results, an educational curriculum will be implemented in order to train residents on the importance of assessing spiritual needs of patients and how to address them properly in a clinical context. We will use other models that have been shown to be successful (2). This will also serve as a baseline for the spiritual demographics of the patient population in Bronx-Lebanon Hospital center for future projects. Methods and Procedures 1. BLHC residents, other mental health providers and patients who are willing to participate will be anonymously surveyed using either a paper or a virtual survey. 2. The survey's questions are both "multiple-choice" and "yes-no" questions, and many of them offer space for residents, other mental health providers and patients to write comments when desired. 3. Residents and other mental health providers will not be asked to write their names or any other piece of personal identifying information on the survey form.

No. 185

First Manic Episode Following the Use of Disulfiram

Poster Presenter: Aarya Krishnan Rajalakshmi, M.D.
Co-Authors: Mamta Sood, M.D., Shyam Roy

SUMMARY:

Introduction: Disulfiram use has been associated with the emergence of psychotic symptoms.Here we report the case of a patient wherein the emergence of manic symptoms had a temporal association with Disulfiram initiation. Case history: Mr.V,a 32 year old married male, was hospitalized in the psychiatric unit of our tertiary care hospital after he was brought by family with complaints of aggression towards them. On evaluation it came through that he had a history infrequent use of Cannabis and Alcohol. Perturbed by his substance use the patient was encouraged by his family members to take once daily tablets of Disulfiram 250mg assuming that it would assist in the patient abstaining completely from all psychoactive substances and the patient and the patient adhered to this regime. Per history, the patient used Cannabis on two occasions in the first 2 days of starting Disulfiram.,after which he discontinued further cannabis use but persisted with Disulfiram use.It was seen that after about 3 weeks of commencing Disulfiram there were notable changes in the patient's behavior in the form of increased cheerfulness alternating with irritability, boastfulness, authoritativeness, increased and loud speech, elaborate planning, grandiose claims, increased need for sex, agitation and argumentativeness escalating to aggression.The patient had no past or family history of psychiatric illness.His family members stopped administering Disulfiram a few weeks after symptom onset and sought treatment.On Mental status examination at the time of admission, the patient was irritable combative, loud, grandiose and expressed ideas of persecution.The diagnosis of Manic episode with psychotic symptoms was entertained.His urine drug screen was negative at admission. Risperidone was initiated and increased to 4mg. There was steady improvement and after 2 weeks his symptoms had substantially resolved. Discussion: Disulfiram has been used in the management of alcohol dependence for several decades now. Its inhibition of Dopamine beta- hydroxylase leading to an increase in Dopamine levels in the mesolimbic system, has been postulated as the possible mechanism underlying psychiatric manifestations seen with Disulfiram.In our patient Disulfiram use for 3 weeks preceding symptom onset The temporal sequence of events, the theoretical potential of Disulfiram to precipitate symptoms of psychosis and

the mention of such events in literature led us to implicate this agent as one which possibly triggered a manic episode in our patient. The likely role of Disulfiram in our patient's illness ,adds to the meager but existing literature on Disulfiram's potential to trigger not only Psychotic, but also classic Manic symptoms.The other aspect to be noted from our elucidation is that here Disulfiram was used in standard doses as opposed to earlier theories that blamed high doses of Disulfiram for psychiatric symptomatology.

No. 186

"Phantom Visions": Charles Bonnet Plus Syndrome or Late-Onset Paraphrenia?

Poster Presenter: Aarya Krishnan Rajalakshmi, M.D.
Co-Authors: Sen Sen Liu, Sunil Verma, M.D.

SUMMARY:

Introduction: Charles Bonnet syndrome (CBS) refers to the presentation of elderly individuals with complex, persistent visual hallucinations (VH) in individuals who possess insight into these symptoms, lack psychiatric illness/cognitive impairment and invariably have accompanying ocular pathology. Through the years there has been a lack of consensus about the characterization of CBS .Here we present the case of an elderly patient with distressing, recurrent, vivid visual hallucinations with wherein a CBS plus seems to be an apt characterization. The case: The patient is an 81y/o female who was admitted to the medical floors for persistent visual hallucinations .Since the onset 3 months ago the patient had been seeing vivid ,recurring images of animals, children and people having sexual contact that were not visible to other people. She regarded these experiences as real and upsetting. She started refusing to leave home citing fears of being robbed by these 'people' .On account of these symptoms, her Primary care doctor had started her on Risperidone and was increased to 1mg without benefit.The patient had no prior h/o psychiatric symptoms or remarkable memory changes. In the hospital she was alert, oriented with an MMSE score of 27/30.A dementia lab work was normal. Brain imaging showed right medal occipital encephalomalacia while her prior CT a month ago had showed sub acute right tempero-occipital infarction in the PCA territory. Ophthalmology was consulted and she was found to have a 20/60 vision in her right eye and a vision limited to hand movements in her left eye with a 4+ cortical cataract in this eye. She was advised to schedule an Ophthalmology follow up after discharge for cataract removal.When Psychiatry was consulted, it was opined that her symptoms were a presentation of CBS plus. The patient was educated about the nature of these symptoms and the likely contribution of her visual limitation .The need for cataract removal was stressed. Considering the lack of improvement with Risperidone and due to new onset resting tremors after increase in dose of Risperidone, it was discontinued .The patient was eventually discharged with the instructions to follow up with Ophthalmology. Discussion: " True CBS" is regarded as a syndrome with complex VH, presence of insight, absent psychiatric symptoms or cognitive difficulties and the presence of ocular pathology.Howard in 1994 remarked on the rarity of "true CBS" presentations and made a case for "CBS plus" to refer to elderly individuals who present with CBS type VH but do not otherwise fit the bill for "True CBs".Our patient's symptoms aligned closest with a CBS plus as opposed to a more nonspecific category of paraphrenia or Unspecified Psychosis.Of further interest in our patient were the coexistence of peripheral ocular pathology and the presence of right tempera-occipital encephalomalacia drawing support to the de afferentiation theory of CBS type VH.

No. 187

Treatment-Resistant Catatonia in Underlying NMDA-Receptor Encephalitis

Poster Presenter: Faiz Hasan
Co-Author: Christopher Burke

SUMMARY:

Ms. T., an 18-year old Asian-American female with a past psychiatric history of depression presented to the psychiatric consult service with medication resistant catatonia during first break psychosis. Her initial presenting symptoms included paranoia, social withdrawal, restlessness, and behavior inconsistent with her norm as per family. The medical and neurological workup for metabolic abnormalities, encephalopathy, and endocrine disorders were inconclusive. She then presented to psychiatry with

a suspected diagnosis of first episode psychosis and was tried on Haloperidol, later switched to Olanzepine; this resulted in the patient exhibiting signs of catatonia—she was mute, eyes volitionally shut, bed-bound with absence of oral intake. After failed trials of Lorazepam, titrated up to 16mg/day with poor response, she was transferred to our consult psychiatric services from the tertiary center for electro-convulsive therapy (ECT) to treat the catatonia unresponsive to medication management. Repeated medical and neurologic workup proved inconclusive once again, leading to the initiation of ECT. After 11-treatments with poor response and further deterioration, including respiratory depression and AV-disassociation, the clinical diagnosis of NMDA-receptor encephalitis was introduced and appropriate serum/CSF biomarkers were drawn and pending results but treatment was started immediately. After the 2nd high-dose of Methylprednisolone, the patient awoke from her state of "catatonia" and improved dramatically. Weeks later, test results confirmed the diagnosis. In this poster, we discuss the challenges and importance of balancing medicine and psychiatry, especially in young adults presenting with first-break psychosis.

No. 188

Psychosis Secondary to Baclofen Withdrawal: A Case Presentation

Poster Presenter: Faiz Hasan

SUMMARY:

Mr. J., a 48-year-old Hispanic male with a past psychiatric history of chronic alcohol use disorder, presents to the emergency room with fever, altered mental status, spasticity, and visual hallucinations. The patient's last alcoholic drink was 16 hours ago and thought to be in withdrawal, as the patient has multiple prior admissions for this reason. With limited history, he was admitted to the inpatient services and started on intravenous fluids, tapering Lorazepam, and Thiamine. The consult psychiatry team considered the differential diagnoses of alcohol withdrawal, serotonin syndrome, and benzodiazepine withdrawal. Initially, the patient's condition improved clinically but he continued to have visual hallucinations throughout his stay. This led to the concern of suboptimal management of alcohol withdrawal but as per CIWA protocol, the patient was detoxified appropriately. A thorough investigation through collateral information obtained from the patient's sister revealed that he's had a minor motor vehicle accident several months ago and since, the patient has been taking some medication to help "relax his muscles". The patient has a history of noncompliance with medication instructions and reports taking higher doses due to pain.This history gathering helped identify that the source of his presenting symptoms were due to acute Baclofen withdrawal. The patient was restarted on the medication and tapered off with full resolution. Baclofen withdrawal commonly mimic psychiatric disease and in this poster, we discuss the significance of pharmacotherapy and its role in differentiating and treatmenting withdrawal symptoms.

No. 189

The "Reading the Mind in the Eyes" Test: Investigation of Psychometric Properties and Test-Retest Reliability of the Persian Version

Poster Presenter: Ladan Khazai, M.D.

SUMMARY:

The "Theory of Mind" is the capability of attribute mental states to the self and to others in order to predict behavior. Several studies have found that conditions such as autism, Schizophrenia and anorexia nervosa, involve a difficulty in recognizing another's state of mind. The "Reading the Mind in the Eyes test" is a simple measure which has been widely used. The revised version has 36 pictures of the eye region and the participants have to one of the four words that best describes the mental state of the person in picture. The main aim of the present study is to study the Eye's test validity and reliability in Persian population. The test was designed as an online test and was distributed online via email and social networks. Data collection lasted for three months and in order to evaluate test-retest reliability, a subgroup of participants was invited to answer the test one year later. A total of 545 volunteers s took part; N=282 women (51.7%) and N=263 men, with a mean age of 25.8 (SD 6.21) Range 16 to 69. Distribution of responses: the mean score of all participants was 22.76 (SD=3.41, min=9,Max=31). Validity: as different authors have

previously mentioned, validity is difficult to investigate since there is no gold standard to be used. Test-retest reliability: We found no significant difference between the scores of participants who performed the test twice (P=0.709).Gender differences: females on average performed better than males. Females' mean score was 23.13 (SD=3.16), which in comparison with males' mean score 22.43 (SD=3.36) was significantly higher (P=0.016). Academic degree and field of study: no significant differences were detected either among different field of studies (P=0.235) or among different academic degrees (P=0.076). SPSS version 11.5 was used to analyze the data. Considering the Empathizing-Systemizing (E-S) theory, our study has led to some notable findings. First of all, among those studied Humanities and Engineering, there were significant sex differences, with females scoring higher in the first and males in the second. This is consistent with E-S theory that predicts those with the S type brain, which is more common among men, tend to analyze and construct rule-based systems" rather than to identify another's mental states and to respond to these with an appropriate emotion. However, opposite to what theory predicts, we found no significant differences among various fields of study in performance on the Eyes test. The Eyes test is an easy-to-use, easy-to-score measure of facial affect recognition. This study indicated that psychometric properties of the Persian Eyes test, the revised version for adults, are generally acceptable except for Item 9 and 29 which its translations have to be reconsidered both in target and foils , regarding their failure according to several criteria.

No. 190

Integration of Mental Health and Primary Care: A Person-Centered Approach

Poster Presenter: Ladan Khazai, M.D.

SUMMARY:

There is a high prevalence of mental disorders among people presenting to primary care settings. Like-wise, people with mental disorders have high rates of physical disorders. Addressing behavioral health problems in primary care is essential because of the prevalence of these problems in primary care setting with reported prevalence of smoking at 20%, obesity at 30% and sedentary lifestyle at 50%. Chronic conditions that require a behavioral health component in a standard care protocol include asthma, diabetes, cardiovascular disease, irritable bowel syndrome obesity and substance abuse. Primary care practices are de facto where the overwhelming majority of patients with mental health problems receive care. There is mounting evidence demonstrating that integrated care improves access to both mental health and physical health services, decrease stigma of receiving mental health care, improves outcome and reduces health care costs. Integration may need to be addressed at multiple levels' at the systems' level, providers' level, interventions' level, patient's level. At the system's level, major factors such as financing of care and facilitating access to care need to be addressed. At the providers' level, training and commitment are essential. Medical care providers need to have enhanced training in mental health and substance abuse recognition and need for intervention. Likewise, mental health and substance abuse providers need to have enhanced training in the recognition and need for intervention for medical problems. At the interventions' level, there is a need to identify, select, and develop integrated pharmacological or psychosocial interventions that are most appropriate for the patient. At the patients' level, there is a need to increase awareness and participatory, protagonist role in the process of care. The emerging PID model considers the person-in-context as the center and goal. It views the process of care as a partnership approach, including the patient, family, care givers and the stakeholders forming a health support network. The first level includes the assessment of health, such as physical or mental disorders along with assessment of functional abilities. The second level is the assessment of contributors to the health status. The third level is the experience of health which includes the experience of wellbeing and experience of ill health. These subjective contributions to the process provide idiographic narrative crucial for empowerment, engagement, partnership and recovery. Refocusing medicine from an essentially disease-centered,"reactive" attitude to an approach focusing on disease prevention and health restoration with emphasis on enhancing wellbeing and health living calls for integration of care. The PID

model provides an overarching conceptual framework for integrated care .

No. 191
Gender Comparison on Quality-of-Life and Comorbid Alcohol Dependence and Major Depression
Poster Presenter: Ladan Khazai, M.D.

SUMMARY:
Compared to men, substance-addicted women have greater social vulnerabilities that may impact their symptom presentation and overall quality-of-life (QOL). The latter is gaining prominence as an outcome measure and key element of person-centered care. We aimed to compare in this study treatment-seeking men and women with co-morbid alcohol dependence and major depression on measures of depression severity, addiction severity, and quality-of-life and to examine associations between addiction/depression severity and quality-of-life separately in men and women. Men (n=34) and women (n=33) participating in a psychopharmacology trial for co-morbid alcohol dependence and major depression were administered the Addiction Severity Index (ASI), the 25-item Hamilton Rating Scale for Depression (HAM-D), and the Multicultural Quality of Life Index at baseline as part of a large assessment battery. Women reported greater QOL impairment than men despite being similar on measures of depression and addiction severity. Depression severity, but not addiction severity, was significantly associated with QOL impairment in both men and women. Treatment-seeking women with co-morbid major depression and alcoholism report lower QOL (I.e., happiness and life satisfaction) than their male counterparts. Depressive symptoms, but not addiction-related problems, may contribute to global QOL impairment. Alternatively, QOL impairment may increase depressed mood. Overall, QOL assessments may identify areas of impairment and opportunities for health promotion not assessed through traditional measures used in addiction treatment programs, and these measures may be more sensitive to the specific needs of women. Consideration of all these factors is likely to enhance person-centered care.

No. 192
Dexmethylphenidate XR-Associated Orofacial Dyskinesia in an Adolescent
Poster Presenter: Mandar Jadhav, M.D.
Co-Authors: James Waxmonsky, Raman Baweja

SUMMARY:
Introduction: Orofacial dyskinesias are involuntary repetitive movements of the mouth and face, which are commonly seen in patients who are on long-term treatment with antipsychotic drugs. This condition has been also reported with use of antidepressants, mood stabilizers, anticonvulsants, antiemetics and other medications (1). Described herein is an unusual case of dyskinesia associated with use of dexmethylphenidate XR developing in an adolescent female despite her having previously tolerated the medication well for over five years. Case History: Our patient is a 14-year-old female with diagnoses of autism spectrum disorder, ADHD and panic disorder without agoraphobia. She was on a combination of medications which included dexmethylphenidate XR 20 mg, escitalopram 20 mg, and clonidine 0.1 mg. She presented to clinic with emergence of orofacial dyskinesia (lip smacking, puckering and facial grimacing) during a routine follow-up visit. The movement was reported to start after she would take her morning dose of dexmethylphenidate XR 20 mg, and last until late afternoon. As per family report, a similar reaction to dexmethylphenidate XR had occurred in her sister and her mother had also had a history of dystonic reaction to metoclopramide. Once the dexmethylphenidate XR 20 mg was discontinued, our patient's orofacial dyskinesia resolved completely. She has subsequently been doing well while taking methylphenidate IR with no recurrence of dyskinesia being reported at two and three-month follow-up visits. Discussion: There are limited reports in the literature about methylphenidate induced orofacial dyskinesia (2). To the best of our knowledge, this is the first case of dexmethylphenidate-ER induced orofacial dyskinesia. In a large, multi-center, double blind, placebo-controlled, parallel-group trial of dexmethylphenidate XR, only one case of musculoskeletal stiffness was reported. In that case, the symptom resolved upon discontinuation of the medication (3). In developing our patient's plan of

care, and in reviewing the literature, we carefully considered several other possible etiologies for the reported symptom, but given the rapid resolution of symptoms after discontinuation of dexmethylphenidate XR, and finding no compelling evidence for the other etiologies, we concluded that the abnormal movement was associated with the medication. While the possibility of motor tic disorder cannot be ruled out completely, the onset of the movement being right after the morning dose of dexmethylphenidate XR being taken, the fact that the dyskinesia lasted until late afternoon, and that the symptom completely resolved after discontinuing the medication, make the likelihood of tic disorder as an alternate etiology very low. This case highlights the importance of continuous monitoring for the emergence of abnormal movement disorders when using dexmethylphenidate XR, even if the patient has been tolerating the medication well.

No. 193

Pharmacological Treatment of Cannabis Related Sleep Disturbance: A Systematic Review of the Literature

Poster Presenter: Naista Zhand, M.D.
Co-Author: Robert Paul Milin, M.D.

SUMMARY:

Background: Cannabis use and cessation both impact normal sleep architecture. While the relationship between active cannabis use and sleep is more complex, sleep disturbance is one of the hallmarks of cannabis withdrawal. Studies have indicated that treatment of this key symptom may facilitate abstinence. Method: We conducted a systematic literature search across five electronic databases including PubMed, Psycinfo, MEDLINE, Cochrane review and Embase. Human studies using a pharmacological treatment for sleep disturbances associated with cannabis use or withdrawal were included. Review articles, case-series, open trials, posters and editorials were excluded. Results: Seventeen publications, involving 562 participants, were included in this review. Major limitations involved small sample size, high dropout rate, methodological limitations and heterogeneity of participants. Most of the studies were at high risk of bias, further downgrading the level of evidence. A meta-analysis was not performed due to lack of quantitative data, marked heterogeneity and low quality of the included studies. Conclusion: There is not sufficient evidence for any of the reviewed treatment options. Methodological limitations in a majority of the studies rendered their findings preliminary. Of the twelve investigated pharmacological agents, Quetiapine, Mirtazapine, Gabapentin, Lofexidine and Zolpidem showed some primary benefits for treatment of sleep difficulties associated with cannabis withdrawal; however future prospective studies are required to confirm such results. Scientific significance: This review examines the current evidence for potential pharmacological options for treatment of cannabis withdrawal and associated sleep disturbance. It furthers our knowledge and provides groundwork for future research on two potential agents Quetiapine and Gabapentin.

No. 194

Seeing Beyond Enucleation: Use of Clozapine After Suicide Attempt in a Schizoaffective Male

Poster Presenter: Nora Jane Carson, M.D.

SUMMARY:

Background: Clozapine has been shown to reduce suicide risk in schizophrenic and schizoaffective individuals. This robust effect is independent of increased provider contact and is not circumscribed to treatment-resistant schizophrenia. Yet, clozapine prescription rates in the United States remain below those of comparable countries, and below rates of treatment-resistant schizophrenia. We aim to highlight the utility of clozapine in managing suicidal behavior, as well as the complexities in managing autoenucleation. **Methods:** This case study explores the management of an acutely suicidal schizoaffective male patient with prior self-inflicted enucleation. **Results:** Patient AR is a 61-year-old male diagnosed with schizoaffective disorder, bipolar type. In the years prior to presentation, he enucleated his left eye, and while psychiatrically hospitalized, made an attempt to enucleate the right, with resulting complete vision loss. He presented to our care several months after blinding himself, acutely suicidal, having used a butter knife to pierce through his left orbit. Clozapine was initiated in light of his high suicide risk, and given

prior treatment failure of two antipsychotics. Valproic acid was started for its dual efficacy as a mood stabilizer and antiepileptic, deemed medically necessary given AR's intracranial trauma. During hospitalization, his suicidal thoughts and self-harm gestures abated, and affect brightened concurrently. **Discussion:** This case is consistent with existing research demonstrating efficacy of clozapine in treating suicidal behavior. Though in this case clozapine was used after treatment failure with two antipsychotics, the literature supports earlier use of clozapine in those at high risk for suicide. We consider that such use of clozapine in AR's case may have led to a better outcome. Further, this case adds to the scant literature regarding enucleation as a self-harm behavior associated with psychotic spectrum illnesses. As in this case, Fan, 2007, found that bilateral autoenucleation is common, even under hospital supervision. Conclusion: Clinicians should recognize the inappropriately low clozapine prescriptions rates in the U.S., the indications for clozapine use, and the unique benefits of clozapine in mitigating suicide risk.

No. 195

Hand to God: Cannabis Psychosis and Withdrawal

Poster Presenter: Nora Jane Carson, M.D.

SUMMARY:

Background: Changes in the political climate are paving the way for the legal expansion of medical and recreational cannabis use in the United States, increasing the need for clinicians to understand the potential risks of this drug. While cannabis has been shown to induce transient dose-dependent psychotic symptoms, there is also evidence of an association between cannabis use and development of schizophrenia, though a causal link has not been established. In a large prospective study, persons with an initial diagnosis of cannabis-induced psychosis had a 46% chance of later diagnosis of schizophrenia spectrum disorder at 8-year follow-up, and cannabis-induced psychosis conferred the highest risk of conversion to schizophrenia among common drugs of abuse studied. Additionally, studies support the existence of cannabis withdrawal syndrome, newly recognized as a diagnosis in the *Diagnostic and Statistical Manual of Mental Disorders* Fifth Edition, with both somatic and psychiatric manifestations that rarely come to medical attention. **Methods:** The following is a case report of a 20-year-old female college student with a 6-year history of daily marijuana use, without other significant substance use or psychiatric history, treated at a large university medical center. Four days prior to presentation, she abruptly discontinued marijuana use. During this period of abstinence, she reported feelings of extreme anxiety, restlessness, sweating, paranoia, and developed a preoccupation with religion, having not previously been religious. Referencing a biblical passage, she amputated her right hand with a kitchen knife. The patient was admitted to a large university medical center, and was closely followed by the Psychiatric Consultation service. Re-attachment of the hand was attempted but failed. She was treated with aripiprazole 10mg daily, clonazepam 0.5mg twice daily, and trazodone 50mg nightly. Assessments were lacking persistence of mood or psychotic symptoms. She did not attempt any further self-harm behaviors and maintained good insight and reality testing. **Conclusion:** To our knowledge, the psychiatric literature on this subject, severe self-mutilation associated with non-synthetic cannabis use, consists only of case reports. While adding to the scant literature on this matter, this case also highlights the importance of further research aimed at understanding the expected outcomes and appropriate treatment course after such an episode. The current study presents a case of brief psychosis and extreme self-harm behavior in the context of heavy marijuana use and abrupt discontinuation. The patient exhibited symptoms consistent with sequelae of cannabis use and cessation commonly documented in psychiatric literature, psychosis and withdrawal, respectively, while also suffering severe self-inflicted mutilation that is rarely associated with cannabis use.

No. 196

Multiple Sclerosis With Catatonic Presentation in Patient With Major Depression

Poster Presenter: Rama Yasaei
Co-Author: Abdolreza Saadabadi, M.D.

SUMMARY:

We are presenting a rare presentation of Multiple sclerosis patient that presented with catatonia which

emphasize the association of these two condition. Case presentation: This is a 51-year-old right handed female who was admitted to the mental health hospital with diagnosis of Depression with psychotic features and catatonic state. On admit, patient was refusing to walk secondary to lower extremity weakness. She was also not bathing or eating. She endorsed some suicidal ideations and auditory hallucinations as well. She ambulates with her walker. Her lower extremity weakness started on the way to the hospital and has slowly been getting worse. she complained of a full body pain, but didn't provide any details. She stated "doesn't know how to walk". She endorses auditory hallucinations and says there are "many voices" that tell her to hurt herself. After Neurology consult, CT Head performed, which was unremarkable with no masses, midline shift or other acute intracranial processes. Neurological exam reveals no motor or sensory deficits in bilateral lower extremities. She does have hyperreflexia in her legs and so MRI cervical spine and brain and CSF study performed. Per MRI brain report, Multiple right frontal juxtacortical nonenhancing white matter lesions, left pericallosal and posterior callosal white matter nonenhancing lesions, bilateral peritrigonal white matter nonenhancing lesions, right larger than left, large left central pontine white matter lesion, and two large right middle cerebellar peduncle nonenhancing lesions are identified, compatible with demyelinating process such as multiple sclerosis. Per MRI neck report, Patchy abnormal signal on the STIR and T2 weighted images in the cervical cord. The findings were relatively nonspecific but primarily include demyelinating process such as multiple sclerosis or acute disseminated encephalomyelitis. Inflammatory process is not excluded. Infection is rare but also not completely excluded. CSF serological test showed positive CSF olgoclonal Bands, high IgG, albumin index, and IgG index. Patient was diagnosed with Multiple Sclerosis comorbid with Major depressive disorder with psychotic feature. Patient was treated for depression and was referred for further evaluation and treatment to outpatient neurologist. Conclusions: Neurological disorders should be always in differential diagnosis of patients with new-onset catatonia, and before making the diagnosis of Catatonia, we should rule out these disorders like MS by neuroimaging and other types of investigation studies. Therefore, we can have a better understanding of the disorder, manage the patient's symptoms, pursue the treatment of patient, and reduce the risk of misdiagnosis.

No. 197

Sudden Sensorineural Hearing Loss Associated With Polysubstance Overdose

Poster Presenter: Rama Yasaei
Co-Author: Kofi Owusu-Antwi

SUMMARY:
Methadone, a long-acting synthetic opioid agonist, has cross-tolerance with other opioids including morphine and heroin, and offers very similar effects but for a longer duration of time, thus is mainly used for opioid addiction. We present a case of a 21 year old female who developed bilateral sudden sensorineural hearing loss (SSNHL) after use of methadone after a long period of abstinence from opioids. We propose opioid receptor normalization-up regulation-sensitization in period of abstinence as the predisposing factor for methadone-induced bilateral sensorineural loss. The exact pathogenesis of hearing loss after drug intake remains unclear, although some theories have been offered. One of the theories explains that the cochlea is one of the highly active structure of human body with rich blood supply (mainly from basilar artery) to provide nutrients oxygen and drugs to this part of the body. Vasospasm of the arteries can cause ischemic stroke of inner ear and in some cases leading to SSNHL. Studies have shown the distribution of 4 types of opioid receptors in cochlea and vestibular system of pigs and rats models. The sensory neuronal loss due to overdose of opioids is rare and there are only few cases reported. Review of six published cases showed complete resolution in 4 out of 6 cases and 2 out of 6 resulted in severe permanent sensorineural loss. In one of the cases that reported on 2011, patient's hearing lost didn't improve after 5months despite the treatment with multiple doses of corticosteroid. There is a case report about the 24-year-old male with brief SSNHL after inhaling crushed Oxymorphone Extended release tablet. Also there is a case report about 2 cases in 2010 with acute bilateral Methadone-induced hearing loss which both resolved in less than 24hours, in urine

toxicology of both patients only Methadone and THC were positive. The fact that most of these cases are affected by Multiple drugs, make the diagnosis more chalenging, but the only common factor between all the reported cases is Methadone. One factor in this case is that Ms.S was incarcerated and was therefore not using illicit drugs or Methadone until her release when she began her usual dose of Methadone (90mg).

No. 198

CAPACITY: A Helpful Mnemonic for Capacity Evaluations

Poster Presenter: William Levitt, M.D.

SUMMARY:

Capacity evaluations are frequented requested on medical floors for a variety of reasons. The elements of capacity and not always understood, as some understand capacity to be an all encompassing principle as opposed to varying by time frame or task. The dictionary defines capacity simply as the ability to do, experience or understand something. While the definition is simple, the assessment may be complicated. Residents and students frequently use mnemonics to memorize information and I propose using this mnemonic when doing a CAPACITY evaluation C Communicate--> Can they Communicate? Do they have free Choice? A Appreciate--> Do the Appreciate the problem/medical condition? P Psych--> Is their decision affected by psychosis or depression? A Alternatives--> What are the alternatives to treatment? C Consequences--> What are the consequences of accepting or refusing treatment? I I can refuse!--> Do they understand they have the right to refuse treatment? T Treatment--> What is the proposed treatment? Y Reliability--> Is this opinion consistently expressed and reliable?

No. 199

Divided Doses of Suboxone: A Physiological Versus Psychological Need?

Poster Presenter: William Levitt, M.D.

SUMMARY:

Suboxone in a combination medication consisting of buprenorphine and naloxone (Bup/Nx) which is FDA approved for the treatment of opiate dependence. Buprenorphine has agonist effects at mu and delta opioid receptors and antagonist effects at kappa opioid receptors. The naloxone is a mu antagonist that functions to produce opiate withdrawal in the case of diversion. It is available in sublingual film (Suboxone) and tablets (Zubsolv) in addition to buccal (Bunavail) film preparations. Bup/Nx has been shown to effective in the office based treatment of opiate dependence. Bup/Nx has a half life between 24-42 hours and is indicated for once a day dosing. However, greater that 90% of patients in our clinic have reported feeling that the dose does not last all day if taken in the morning. However, the same dose is reported to be sufficient to control cravings and urges if divided in to two to three doses daily. As we have seen that most patients in buprenorphine clinic prefer to divide doses, we will attempt to look at the number of patients on long term maintenance who divide doses who create their own dosing schedule and look into psychological and physiological reasons for the need for divided dosing.

No. 200

Stiff Person Syndrome Presenting After the Initiation of Buspirone

Poster Presenter: Ibrahim Mohammad Mousa Sablaban, D.O.

SUMMARY:

Stiff Person Syndrome (SPS) is a rare, potentially debilitating, disease of uncertain etiology. The clinical features include muscular rigidity and spastic spells. However, clinical presentation is complex and patients often present with symptoms of panic attacks and autonomic instability. We describe a case of a 32-year-old patient with a history of depression and panic disorder who presented to the emergency room with signs and symptoms of shock and hyperthermia. Prior, the patient had a panic attack that coincided with the first-time administration of buspirone. The patient had a temperature of 105F, was found to be hypotensive and had oxygen desaturation. The patient was sedated, intubated and treated empirically with antibiotics as she was found to have a white blood cell count of 39,000. CT scan and lumbar puncture were normal. Over the next 30 days, various investigations for carcinoid, pheochromocytoma, porphyrias, and endocrine disorders did not yield a

diagnosis. Ultimately an exhaustive autoimmune and paraneoplastic workup was conducted yielding a markedly elevated GAD65 antibody titer of 1430 nmol/L. A diagnosis of Stiff Person Syndrome was made. The patient responded to treatment with regularly scheduled diazepam, was extubated prior to discharge, when the symptoms had subsided. While the etiology of SPS is unknown, a hypothesis based on the hindrance of gamma-aminobutyric acid (GABA) production via intrathecal autoantibodies to glutamic acid decarboxylase has been presented in the literature. A review of literature yields no prior appreciation of buspirone precipitating SPS. It is possible that the sympathomimetic nature of buspirone, explained by the established excitatory effect it has on the noradrenergic activity of the locus coeruleus, may have played a role in the precipitation of this episode. Although we can not definitively attribute causality, this case stresses the importance of further investigation and study of the potential relationship between buspirone and SPS.

Designing an Innovative, Multidisciplinary Treatment Program for Patients With Non-Epileptic Seizures

Poster Presenter: Jacob Gadbaw
Co-Authors: Meagan Watson, Anson Kairys, M.A., Randi Heller Libbon, M.D., Alison M. Heru, M.D., Laura A. Strom, M.D.

SUMMARY:
Background: Historically, access to care for patients with non-epileptic seizures (NES) has been limited. While psychiatric treatment has proven necessary for the treatment of NES, there is no established best practice and few high-quality studies exist to guide treatment. Without appropriate care, these patients suffer a low quality of life, remain on antiepileptic medications, and place unnecessary burden on the healthcare system through overutilization of emergency departments and epilepsy monitoring units (EMU). Methods: In response to this deficit, we designed an innovative, technology centered treatment program that includes psychiatry, psychology, and neurology. To begin, all patients receive a formal, EEG-confirmed diagnosis in the EMU. After an initial assessment, there are several treatment pathways depending on the individual patient's clinical need. These personalized options include a 12-week psychodynamic therapy group, a 5-week psychoeducational group, individual therapy, family therapy, and medication management. The goal is to return patients to their primary care providers with the knowledge and skills necessary to manage their illness within six months of enrollment. Concurrently, we launched an IRB approved, technology assisted research study to evaluate the effectiveness of our clinic. We are using six measures, collected at three time points (at diagnosis, three months into treatment, and after six months of treatment). These measures include the Brief Illness Perception Questionnaire, Short Post-Traumatic Stress Disorder Rating Interview, Quality of Life in Epilepsy Inventory, Brief Cope, Dissociative Experiences Scale, and Family Assessment Device. Seizure frequency is also collected throughout treatment. We programmed these measures into Filemaker Pro which can be accessed through iPads supplied by the neurology department. If a patient's time point falls close to a scheduled appointment, Filemaker Pro automatically informs the front desk during check-in and the patient is given an iPad to complete the measures. If they are due at a different time, the program sends the patient a link via email to complete the measures on their home computer. Filemaker Pro then aggregates all data for analysis. Results: We currently have 87 patients enrolled in the research study. 71 patients have all completed their first set of measures. We have completed six of the psychodynamic groups and 15 of the psychoeducational groups, serving a total of 96 patients. We have active enrollment and data collection to provide feedback on protocols while evaluating the effectiveness of the model. Conclusion: This clinic integrates multidisciplinary teams to provide personally focused treatment for patients with NES. Through leveraging technology, this innovative model allows active evaluation of effectiveness of treatment with the goal to achieve disorder remission and transfer back to the primary care setting.

No. 202

Charles Bonnet Effectively Treated With Quetiapine: A Case Report and Literature Review

Poster Presenter: Jamison A. Bradshaw, D.O.

Co-Author: Walter Kilpatrick

SUMMARY:
Background: Charles Bonnet syndrome (CBS) is characterized by complex visual hallucinations in individuals with partial or severe blindness. First described by Charles Bonnet in 1760, the hallucinations themselves are typically purely visual and Lilliputian in character while sufferers tend to have a lack of prior psychiatric pathology and maintain some insight into the fictitious nature of their hallucinations. Despite this extensive history there is no current evidence-based treatment. This case describes a patient with CBS who experienced resolution of visual hallucinations and restoration of sleep wake cycle through treatment with quetiapine. Methods: A 72-year-old male presented to the emergency department after his family noticed increasing aggressive behavior, visual hallucinations, and loss of normal sleep-wake cycle. He described seeing classical lilliputian-like figures at home. His initial medical evaluation included a CBC, LFTs, and BMP which did show results consistent with ESRD but nephrology did not believe this to be significant to his presentation. A CT head did not show any acute abnormalities. We utilized PubMed and Medline for our literature review. Results: On mental status examination, the patient was found to be calm and cooperative without any apparent distress. His thought process was linear, coherent, and goal directed and there was no evidence of paranoia or delusional thought content. His attentional, concentration, and cognition were intact. He had no prior psychiatric history. He was reassured that this was not a psychotic episode and was started on quetiapine 50 mg qHS for treatment of visual hallucinations and restoration of his sleep-wake cycle. Discussion: A majority of case reports describing the treatment of CBS utilize olanzapine as the treatment agent from CBS. However, in two recent case reports reports, similarly to our patient, quetiapine was an effective treatment that eliminated his hallucinations and restored his sleep wake cycle. This case reinforces the efficacy of Seroquel monotherapy in the treatment CBS. Conclusion: Clinicians who are involved in the treatment of Charles Bonnet Syndrome should be aware that, based on recent case reports, quetiapine may be be emerging as an effective treatment option.

No. 203
Chronic Limb Pain: The Importance of Differentiating Complex Regional Pain Syndrome From Somatic Symptom Disorder
Poster Presenter: Jasmin G. Lagman, M.D.

SUMMARY:
Children and adolescents suffering from chronic pain have higher probability of endorsing elevated pain-related fear which is then associated with high levels of disability, depressive symptoms and school impairment. Presented here was a suspected patient with conversion disorder or functional neurologic symptom disorder who was initially diagnosed as a case of complex regional pain syndrome (CRPS). Case presentation: Patient was a 12yo female who was seen at an inpatient children rehabilitation facility for prolonged lower extremities pain with eventual loss of the ability to walk. Her mother was suffering from CRPS for many years. She was well and playing multiple sports days preceding the onset of pain. She succumbed to depression and had increased anxiety attacks. Patient expressed resignation on her ability to become better, noting her mother's years of struggle with pain. She endorsed fears on the thoughts of pain, and of being on more pain if her treatment fails. Her pain started 5-6 months and saw her pediatrician, two orthopedic surgeons, a rheumatologist, and later a palliative care specialist who diagnosed her with CRPS. She was prescribed with Gabapentin and was referred to an inpatient rehab for functional optimization. At one point, she saw a psychiatrist who started her on Cymbalta. Patient was described by her family as perfectionist and was an honor student. She felt that it was her responsibility to make her mother happy, and thus she needed to be perfect. She denied difficulties in school or other issues. Course in the wards: On admission, she had limited range of motion and decreased muscle strength in the lower extremities, negative imaging, and screening blood work. Her weakness and the location of the pain were not strongly correlated. The pattern of the weakness was not myotomal and allodynia was diffuse. This led to psychiatry consult for a possible conversion disorder. Due to patient's excessive thoughts

associated with the pain, persistent high levels of anxiety about her health and seriousness of her symptoms, and the inability to use her lower extremities due to pain, somatic symptom disorder was diagnosed. The multi-disciplinary treatment approach was changed. No pain medication was provided and therapy was focused on the child's ability to function. The pain was not discussed. The patient showed rapid improvement in symptoms and by the end of the third week, she was walking without any supports. Discussion: Both conversion disorder and somatic symptom disorder are separate disorders and belong to somatic symptom and related disorders in DSM 5. Since symptoms may appear as a medical condition, the diagnosis is complex. CRPS is a complex chronic pain experience and involves a multi-disciplinary treatment approach. Distinguishing between these types of disorder is important as seen in this case.

No. 204

Clozapine Withdrawal and Malignant Catatonia: A Case Report

Poster Presenter: Leonid Kapulsky, M.D.
Co-Author: Miranda Geniece Greiner, M.D., M.P.H.

SUMMARY:
Malignant catatonia is a severe, potentially life-threatening variant of catatonia marked by hyperthermia, autonomic instability and rigidity. The condition is often viewed as being on the same spectrum as neuroleptic malignant syndrome. Causes of malignant catatonia include antipsychotic medications, illicit drug use, and intoxications with other agents. It's also been reported that discontinuation of antipsychotic medications, specifically clozapine, can result in malignant catatonia. This is a report on a case of a 22-year-old Bangladeshi male with a history of schizophrenia who developed malignant catatonia in the setting of clozapine discontinuation. The patient presented to the hospital with mutism, rigidity, autonomic instability and an elevated creatinine kinase that was initially thought to be secondary to antipsychotic-induced neuroleptic malignant syndrome. However, given the fact that clozapine had been discontinued two days prior to presentation, the diagnosis was revised to malignant catatonia secondary to clozapine withdrawal, a phenomenon which has rarely been reported in the literature. The severe episode of malignant catatonia was resistant to high dose parenteral benzodiazepines and ECT but responsive to clozapine reintroduction. Potential mechanisms for this phenomenon are discussed. A thorough history of current and recently discontinued medications should be taken in all patients presenting with malignant catatonia because the treatment for patients with "discontinuation" catatonia may be different than for those with catatonia of a different etiology.

No. 205

Clozapine-Induced Myocarditis: A Treatment Algorithm

Poster Presenter: Martha J. Ignaszewski, M.D.
Co-Authors: Adam Chodkiewicz, Tamara Mihic

SUMMARY:
Myocarditis is a relatively rare adverse effect associated with the use of clozapine, however there is growing interest and awareness due to increasing reports of global cases of clozapine-induced myocarditis far exceeding the initial incidence rate reported in the product monograph (clozaril product monograph, Yousseff 2016). Management revolves around early recognition of the disorder, prompt discontinuation of clozapine, and multidisciplinary management. We present a case series of three patients who developed myocarditis in the course of hospitalization and clozapine treatment. We will review the pathophysiology for underlying clozapine induced-cardiotoxicity and present the multidisciplinary adverse-effect surveillance program that has been developed for use and prevention at our institution for patients initiated on clozapine. We will also highlight a newly developed biomarker based pathway where use of C-reactive protein (CRP) and cardiac troponin I allowed for early identification of myocarditis, and review the literature that supports this approach.

No. 206

The Psychiatric Fits: A Complex Presentation of Complex Partial Seizures

Poster Presenter: Martha J. Ignaszewski, M.D.
Co-Author: Shadi Zaghloul, M.D.

SUMMARY:

Objectives: Although seizures are common and symptoms are well described, diagnosis may be difficult in patients with neuropsychiatric or atypical manifestations. Psychiatrists are frequently consulted to assess patients whose symptoms have been labeled “behavioural” or “psychiatric”. We highlight factors to distinguish ictal psychiatric symptoms from primary psychiatric phenomena and review comorbidity with psychogenic non-epileptic seizures. We also explore the psychiatrist’s role as patient advocate when diagnostic opinions conflict to prevent premature closure. Methods: We collaborated with the Baystate Medical Center Department of Pediatrics, Neurology and EEG Laboratory. We utilized PubMed and Medline for our literature review. Results: Our patient is an 18-year-old Caucasian male with a history of treated epilepsy, who is medically admitted for workup of recurrent episodes described as “auras…with a state of disconnection…like a bad dream”. These were associated with extreme anxiety, somatic symptoms similar to PD, occurring 5-8 times daily, with high inter-episode distress about recurrence. He experienced “screaming in my head” with vivid dreams that he “struggled to differentiate from reality” and paranoia regarding the safety of locations that triggered attacks. Psychiatry was consulted for evaluation of “psychosis vs AD”. Psychiatric recommendations emphasized the importance of a thorough medical workup to exclude other etiologies that could mimic symptoms of generalized anxiety and panic attacks. EEG findings revealed an epileptogenic process in the right anterior temporal region, diagnosed as breakthrough seizures. He was started on oxcarbazepine with resolution of symptoms. Conclusions: The general hospital psychiatrist must be able to differentiate primary psychiatric disorders and possess a comprehensive knowledge of seizure disorders and the common accompanying neuropsychiatric syndromes to allow for accurate diagnosis. Atypical symptoms and high rates of psychiatric comorbidity may further complicate diagnosis. This underscores the importance of maintaining a broad differential and ensuring that patients are provided a comprehensive medical workup when clinical doubt is introduced, and to serve as patient advocates for additional workup to prevent premature diagnostic closure and misdiagnosis.

No. 207

Determinants of 30-Days Psychiatric Readmissions in an Academic Safety-Net Psychiatric Hospital

Poster Presenter: Pratikkumar Desai, M.D., M.P.H.
Co-Author: Jane Hamilton

SUMMARY:
Background Around 13% of psychiatric patients are readmitted soon after being discharged from acute inpatient psychiatric hospitals. 30-day readmission after acute psychiatric hospitalization is an indicator of quality and coordination of mental health care. Not only are 30-day readmissions considered adverse clinical outcomes for psychiatric patients, the costs associated 30-day readmissions place a higher economic burden on the health care system. This study examines demographic, clinical, treatment and community factors associated with 30-day readmission to a psychiatric hospital. Methods In this retrospective study, we examined 22,818 consecutive admissions of adult patients admitted to our academic safety-net psychiatric hospital from January 2010 to December 2013. This unit of analysis was a single patient admission, and readmission within 30 days of discharge was the outcome measure. We examined demographic factors including age, race, gender, marital status, employment status, and education level. Clinical factors included the primary psychiatry diagnosis, Global Assessment of Functioning (GAF) score, co-morbid medical conditions, mental health related symptoms. Treatment factors included the number of prior psychiatric hospitalizations and treatment adherence. Community factors included living situation prior to admission. In the adjusted analysis, a multivariate logistic regression model using generalized estimating equations was used to estimate the relative odds of each variable in predicting psychiatric hospital readmission within 30 days of discharge. Results In the adjusted analysis, we found that male gender (OR:1.21, 95% CI:1.08-1.36), no income (OR:1.13, 95% CI:1.02-1.25), being homeless (OR: 1.53, 95% CI:1.3-1.81), history of suicidal ideations (OR:1.27, 1.12-1.43), history of aggression (OR:1.24, 95% CI:1.08-1.41), and having ? 3 psychiatric hospitalizations (OR:4.73, 95% CI:4.21-

5.31) predicted 30-day readmission. Additionally, compared to having commercial insurance, patients who were uninsured (OR:1.77, 95% CI:1.49-2.09), enrolled in Medicare (OR:1.32, 95% CI:1.05-1.66) or enrolled in Medicaid (OR:1.41, 95% CI:1.03-1.93) were more likely to readmit within 30 days of discharge. Older age patients were less likely to be readmitted within 30 days (OR:0.98, 95% CI:0.98-0.99). Patients with depressive disorders (OR:0.74, 95% CI:0.64-0.86) and other psychiatric disorders (OR:0.46, 95% CI:0.29-0.72) were less likely to be readmitted within 30 days compared to bipolar disorder patients. Race, marital status, involuntary admission, treatment adherence, medical co-morbidity and admit GAF did not predict 30-day readmission. Conclusion Early readmission following psychiatric hospital discharge may be highly unsettling to patients and their families. Our findings suggest that interventions to reduce readmissions should target social determinants of frequent admissions to psychiatric hospitals such as employment and living situation.

No. 208

Capturing Medical Necessity: Building an Educational Curriculum to Enhance Clinical Documentation in a Psychiatry Residency Program

Poster Presenter: Ninos Adams, M.D.

SUMMARY:

Background In 2016, the California Department of Health Care Services completed an onsite compliance review of clinical documentation at a 24-bed, Medi-Cal funded acute psychiatric inpatient unit in Bakersfield, California. The purpose of the review was to verify whether patient care provided by the UCLA-Kern Medical Psychiatry Residency Program met acute medical necessity criteria in accordance with state regulations. The review evaluated 66 patient charts encompassing 488 acute inpatient days and concluded that 55% or 270 acute inpatient days failed to meet medical necessity criteria for admission and continued stay services. Appropriate justification of medical necessity is the chief element for determining Medi-Cal reimbursement. Therefore, the alarming disallowance rate resulted in a significant monetary recoupment by the state. As a result, the psychiatry department developed a documentation education curriculum to empower physicians with the skills necessary to capture medical necessity more effectively. Methods The position of a clinical documentation specialist was created by the psychiatry department to study the reasons for disallowance and identify areas for improvement. The documentation specialist hypothesized that documentation could improve with the innovation of a training curriculum as documentation is a skill not generally taught in medical school. The curriculum emphasized the use of standardized progress note templates, frequent didactic lectures highlighting the use of behaviorally-specific language, educational handouts, and most importantly ongoing daily one-on-one training sessions where the documentation specialist reviewed progress notes with physicians and provided feedback. It was important to determine whether the efforts achieved any degree of success. Consequently, outcomes were measured using a treatment authorization request process where a county mental health entity audited charts to determine whether to approve or disallow days on the basis of appropriate justification of medical necessity. Results After 1 month of educational intervention the disallowance rate for acute days dropped to 10% and continued to appreciable decline to 3% after 6 months. Overall, from July 2016 to July 2017 the inpatient psychiatric unit provided services to Medi-Cal insured patients for a total of 6264 acute inpatient days resulting in a disallowance rate of 5%. Conclusion Although the innovation of an educational curriculum required a significant commitment of time and resources, these efforts enhanced the psychiatry department's ability to capture medical necessity. Currently, providers in the department have a deeper understanding about the importance of accurate documentation for patient care and reimbursement purposes. Anecdotally, interpersonal communication increased throughout the psychiatry department as well and surprisingly a majority of physicians continued to welcome feedback to improve their documentation.

Approaches to the Treatment of Delirium in the Intensive Care Setting in a Community-Based Teaching Hospital

Poster Presenter: Ninos Adams, M.D.

SUMMARY:

Background Delirium is defined as a disturbance in attention (i.e., reduced ability to direct, focus, sustain, and shift attention) and awareness (reduced orientation to the environment). Delirium occurs in 70 to 87 percent of those (patients) in an intensive care unit. With over six million admissions to the intensive care setting each year, many would benefit from improved treatment approaches. Methods A retrospective review of all patient's admitted to the intensive care setting at Kern Medical from January 1, 2016 to December 31, 2017 will be carried out. Results At the completion of data gathering, the study will incorporate final data collection and statistical analysis to determine possible approach superiority with respect to differing presenting situations. Conclusions Studies demonstrate that the number of days of intensive care delirium are associated with increased morbidity and mortality. Preventing and decreasing duration of delirium in the intensive care setting via improved treatment approaches will not only benefit the patient by decreasing morbidity and mortality related to it, but will also greatly decrease the burden on the healthcare system as a whole.

"Smart Drug": Tianeptine Abuse, Withdrawal, and Treatment Management

Poster Presenter: Nisha Rao
Co-Author: Elias A. Khawam, M.D.

SUMMARY:

Background: Tianeptine is an atypical antidepressant with unique pharmacological properties. Its therapeutic effect is attributed to an increase in serotonin and dopamine reuptake, and modulation of the glutamatergic system. Tianeptine can potentially be abused as it has psychostimulant effect and full agonist effect on opioid receptors. It is not marketed in the United States but is available in Asia, Latin America, and many Middle Eastern and European countries. This case report provides psychiatrists with information on tianeptine abuse, its opioid-mediated withdrawal symptoms, and treatment management. Methods: We present a case of a 26 year old male with crohn's disease admitted for escalating abdominal pain. He was treated for acute inflammation and stricture at ileocolic anastomosis. Psychiatry consult was requested for depression as patient was on tianeptine and sertraline prior to the admission. Patient admitted to buying tianeptine online, without a prescription, and titrating up to 4 grams per day to manage his depression, pain and to "get high". He developed tolerance and experienced withdrawal symptoms when he tried to reduce tianeptine dose. During admission, he began experiencing symptoms similar to opioid withdrawal including sweating, nausea, muscle aches, hot and cold flashes, in addition to severe anxiety and depressed mood. The psychiatry consult team recommended baclofen, clonidine, gabapentin, and promethazine for tianeptine withdrawal symptoms. Lorazepam was added on as needed basis for severe anxiety that was not being managed by gabapentin or hydroxyzine. He improved with medication management and his withdrawal symptoms abated over 4 days. Results: Medication management improved patient's withdrawal symptoms during this hospitalization. He was discharged on sertraline, gabapentin and tapering dose of baclofen. He was seen for a follow up in outpatient psychiatric clinic within 7 days of the discharge and he reported no withdrawal symptoms. Discussion: Tianeptine, in contrast to other antidepressants, has psychostimulant effect and overtime, leads to increase in drug tolerance. Higher dose of tianeptine acts at the mu-opioid receptors and the drug abstinence results in opioid mediated withdrawal symptoms, which can start quickly because of short half-life. High level of anxiety and depression observed in tianeptine withdrawal could be due to glutamate modulator action. Treating tianeptine withdrawal promptly should result in symptoms subsiding. Conclusion: Antidepressants with opioid agonist effect should concern those treating drug addictions. Although tianeptine is not marketed in the United States, it is widely available through online pharmacies. Being familiar with tianeptine's abuse potential and opioid-mediated withdrawal symptoms helps psychiatrists with treatment management and successful recovery.

Psychiatric Assessment of Emirati Patients Pursuing Bariatric Surgery for Obesity

Poster Presenter: Ossama Tawakol Osman, M.D.

SUMMARY:
Background: Obesity is currently a rapidly growing global problem of epidemic proportions and is especially prevalent in economically developed countries such as the United Arab Emirates. Obese individuals are increasingly considering bariatric surgery as their preferred means of choice for the reduction of excess body fat. This study explored the psychological characteristics that may potentially complicate the surgical management of obesity. Methods: This was a cross-sectional study of Emirati patients attending a bariatric clinic at Tawam Hospital, Al Ain, United Arab Emirates, between December 2010 and February 2012. Participants were assessed using standard clinical psychiatric interviews. Also used were screening instruments such as the Hospital Anxiety and Depression Scale, Sheehan Disability Scale (SDS), Body Image Quality of Life Inventory (BIQLI), and Multidimensional Body-Self Relations Questionnaire–Appearance Scale (MBSRQ-AS). Results: A total of 105 patients, 70% of whom were female, participated in this study. Participants were found to have frequencies of anxiety and depressive symptoms at levels of 24% and 13%, respectively. Participants also reported perceived functional disabilities in the following: work/school (27%), social life (36%), family/home (35%), and religious duties (39%). A total of 13 participants (12%) had BIQLI scores showing slight-to-moderate effects on their quality of life. The mean MBSRQ-AS subscale on self-classified weight was higher than the reported norms. Anxiety and depressive symptoms positively correlated with functional impairment (SDS) and negatively correlated with quality of life (BIQLI) (P = .000). MBSRQ-AS subscales significantly correlated with depression, functional impairment, and quality of life (P = .035). Conclusions: Anxiety, depression, perceived functional disability, impairment in quality of life, and disturbance of self-image were found to be common among participants in the study pursuing bariatric surgery for obesity. Recognition, assessment, and treatment of these symptoms are expected to be conducive to positive outcomes of bariatric surgery.

No. 212
A Case of Convulsive Syncope Mistaken for Psychogenic Nonepileptic Seizures
Poster Presenter: Quincy X. Zhong, M.D.

SUMMARY:
Syncopal episodes can have a wide variety of triggers including strong emotional responses and odors. When the episodes are accompanied by convulsions and have normal EEG findings, it can lead to a misdiagnosis of psychogenic nonepileptic seizures. A 49-year-old woman with a history of sexual trauma and a 15-year history of convulsive episodes was referred for psychiatric evaluation of her spells. The spells began with feeling hot and nauseated, followed by a sensation going from her head through the rest of her body making her feel weak. This progressed to staring, salivation, mouth smacking, facial tics, vocalizations, and rhythmic jerking of her back, arms, and legs that would last a few minutes. She initially remained aware of her surroundings but would eventually lose consciousness. The episodes could last 30 minutes from time of prodrome to time of waking up. She experienced sleepiness and generalized weakness afterward. At their most frequent, the spells occurred several times per day, and were triggered by emotions, heat, and odor. Routine, prolonged (1 hour), and ambulatory (24 hour) EEGs were normal, and witnessed episodes did not appear consistent with epileptic seizures, thus, she was given the diagnosis of psychogenic non-epileptic spells. With psychotherapy and psychotropics, the number of emotionally triggered episodes declined, but she continued to experience episodes triggered by heat and odor. At this point there was suspicion for syncopal convulsions, given the prodrome of feeling hot and nauseated prior to the spells and continued spells despite lack of emotional triggers. Through behavioral interventions such as lying down or cooling off immediately after onset of prodrome symptoms, progression to convulsions was able to be prevented. A new diagnosis of neurally mediated syncope was made. Though the diagnosis of “psychogenic nonepileptic seizures” led to appropriate control of emotional triggers through psychotherapy and medication, this patient remained at risk for syncopal episodes due to other triggers. Awareness of emotions as a trigger for syncope and syncope as a cause of convulsions can lead to appropriate workup and management of syncopal episodes.

No. 213

Delirium: How Does the Blood Test Help Us?

Poster Presenter: Leonardo Hess
Co-Authors: Jaime Mario Kuvischansky, M.D., Antonela Nasello, Javier Monaco, Carla Graziadei, Maria Jimena Matacin, Ezequiel Rodenas, Pablo Bassanese, Romina Martinangeli, Julia Javkin, Manuel Francescutti

SUMMARY:

Introduction Electrolyte imbalances and delirium are frequent problems in hospitalized patients. Although confusional states are consider to be a possible complication of electrolyte disorder it is necessary to analyze the relation these diseases have. Delirium is a neuropsychiatric syndrome characterized by acute change in arousal and cognition arising from an underlying medical injury, it is associated with poor clinical outcome, including personal suffering, cognitive decline, institutionalization after hospitalization, economic costs and risk of death. Methods This is a retrospective and observational study based on 73 patients hospitalized in "Sanatorio Parque", Rosario, Santa Fe, Argentina. The information was collected in a period of 6 months (January 2017- July 2017). All the patients met Confusion Assesment Method (CAM) criteria for delirium. The agitation associated with delirium was measured with the Richmond Agitation-Sedation Scale (RASS). Data were collected from medical records: sub type of delirium, results of blood test, age, sex, clinical diagnosis and the treatment chosen for the management of the condition. The analysed with GraphPad v5.0. Results 102 patients were diagnosed with delirium. 36 of them were dismissed for insufficient data. 54 patients had hyperactive delirium (HD) and 12 hypoactive delirium (HyD). Blood test results were evaluated and most of them had electrolyte imbalances, kidney failure and leukocytosis. Only 8 patients did not present blood test disturbances and were diagnosed as hypoactive, they were all older than 75 years old and had history of cognitive impairment or dementia. The other 4 patients had HyD associated with leukocytosis due to infectious causes. Only 7 patients did not present any electrolyte imbalance, they all had cancer and pancytopenia. 3 of them died the following week. Patients were treated with olanzapine 2.5mg -10 mg /day demonstrating a decrease in the RASS-scale in 24 hs. . First query: mean = 2.8 +/- 1.1 - Second query: mean = 1.2 +/- 1.4 (Pval = <0.01). Those who did not tolerate orally were treated with haloperidol intravenous 5-10 mg / day showing less response. First query: mean = 2.8 +/- 1.1 - Second query: mean = 1.2 +/- 1.4 (Pval = <0.01) Patients who presented as underlying pathology an encephalic cranial trauma, polytum or were over 70 year old required physical restraint. Conclusions The analyzed parameters show differences in the blood test data, according to the presentation of the different types of delirium. It is shown as depending on the different causes of delirium, different approaches are required. The población studied works as a preliminary study, in the future to find predictors of delirium.

No. 214

The Epidemiology of Suicide: A Prospective Study of Risk and Protective Factors Among Suicide Attempters Admitted in an Argentinian General Hospital

Poster Presenter: Leonardo Hess
Co-Authors: Jaime Mario Kuvischansky, M.D., Manuel Francescutti, Ezequiel Rodenas, Javier Monaco, Romina Martinangeli, Antonela Nasello, Carla Graziadei, Julia Javkin, Maria Jimena Matacin, Pablo Bassanese

SUMMARY:

BACKGROUND A suicide attempt is defined as a self-inflected, potentially injurious behavior with a nonfatal outcome for which there is evidence of intent to die. Suicidal thoughts or behavior are not limited to any single diagnostic group or condition. Death by suicide occurs with distressing frequency among many different illnesses, including mood disorders, substance abuse disorders, schizophrenia, and personality disorders. A risk factor is a characteristic, variable, or hazard that increases the likelihood of development of an adverse outcome, 64 which is measurable, and which precedes the outcome. METHODS This is a prospective, descriptive and observational study based on 54 patients admitted in the Emergency department of "Sanatorio Parque", Rosario, Santa Fe. The data were collected in a period of 12 months (January 2016- December 2016). We design a questionnaire

to administrate to each patient with suicide-behavior to define risk assessment. The data were analyzed through the PSPP-Linux software. RESULTS From a total of 54 patients, 43 were women (mean age 30.63 ± 14.8) and 11 men (mean age 42.55 ± 23.12). Pval <0,05. Risk factors, deadliness and severity of the attempt were registered and compared with several variables such as age, sex, schedules, etc. There were many factors related with suicide-attempt risk. This report presents representative data on the protective and risk factors of attempted suicide in an Argentinian population. The majority of the patients were single and had psychiatric history. Most of the attemps were over the weekend. Risk Factors highlighted: age < 20 years old, living alone and family issues as trigger factors. >Lethality: >45 years old, attempt between 0-12 hours; stressful event and chronic disease as trigger factors. CONCLUSIONS This study presents characteristics of self-injurious behaviours in the absence of suicide attempt. Such behaviours are considered to be an aggravating factor, which hinders the patient's progress. These results might be usefull for further investigations.

A Narrative Review of Portrayal of Suicide in Art

Poster Presenter: Badr Ratnakaran, M.B.B.S.
Co-Authors: Ayotunde Ayobello, M.D., Tricia Lemelle, M.D., M.B.A.

SUMMARY:

Background: Human emotions, the context surrounding it and mental illness have been an important theme in art. Scenes of suicide and associated maladaptive emotions have also been depicted in famous painitings. Objective: To identify important paintings depicting suicide and themes related to it. Method: A literature search was done on the depictions of suicide in famous paintings and various experts interested in the field of art and psychiatry were contacted via email for their opinions of the same. Sources used from the internet including websites by The Lost Museum Archive, Wikiart, Wikimedia Commons, E.G Bruhl Collections, Leicester galleries, Wellcome Trust, Tate museum, Museum of Modern art, Metropolitan museum, Museo Del Prado and Philadelphia musuem of Art. Paintings portraying suicide were selected and a narrative review was done by the authors. Results: 75 famous paintings were identified that depicted suicide. The paintings mainly belonged to the Western culture ranging from the gothic, renaissance, neoclassicism, romanticism to modern art. The themes depicted have been suicide in relation to important figures from history, mythology, the Bible and scenes of death after suicide. The methods of suicide depicted are self stabbing, hanging, drowning, self poisoning, jumping from a height, self immolation, cutting one's blood vessels and use of firearms on oneself. The reasons of suicide depicted in the paintings can also be contextualized in relation to Emile Durkheim's theories of suicide. Bereavement, imminent execution/ imprisonment, shame, anger, guilt and sorrow have been the important contexts around which the suicides have been depicted. Conclusion: The depictions of suicide and their context help us in understanding the various causes which causes traumatic experiences leading to intense emotions and eventually to suicide. A knowledge of such depictions will help in understanding the perspectives of suicide in different cultures, philosophies and eras in history.

Increasing Prevalence of Opiates in Maryland Suicides by Objective Testing (2006–2017)

Poster Presenter: Daniel Borota
Co-Author: Paul Nestadt, M.D.

SUMMARY:

Background: The rate of suicide in the US is on the rise. The most recently reported rate is 13.26 per 100,000 persons, the highest since 1986. Similarly, opiate use is increasing. Substance abuse remains one of the most important risk factors for depression and suicide. Prior studies have found increasing rates of accidental opiate overdose as well as opiate use listed as a contributor to death by suicide. However, these studies have relied on nationally aggregated death certificate data, for which there is a lack of uniform death investigation and documentation across jurisdictions. Unlike most states, Maryland uses a statewide medical examiner system. Under this centralized system, autopsies are performed using strict protocols with full toxicology reports on all suicides and unexplained deaths. Objective

measures of opiate toxicology are collected in a consistent manner across all completed suicides in Maryland. Using this data, we evaluated trends in opiate prevalence in suicide decedents in Maryland. Methods: A retrospective analysis was performed on all 5,876 well-characterized suicides in Maryland from 2006 through the first half of 2017. The proportion of decedents who tested positive for opiates at the time of suicide was calculated for each year and logistic regression was used to assess the change in proportion of opiate positive suicide decedents over the 10 year period, controlling for age, sex, and race. We repeated this analysis for presence of cocaine and for alcohol intoxication (BAL>0.08) to determine if any change in prevalence was unique to opiates. Results: Prevalence of positive opiate toxicology increased significantly from 8.8% in 2006 to 17.7% in 2017. Controlling for age, sex and race, this represents an odds ratio (OR) of 2.24 ($p<0.001$, 95%CI = 1.4-3.5). There was no significant change in the proportion of suicide decedents who were positive for cocaine or alcohol intoxication. The largest increases in positive opiate tests were found in 2014-17. The increase was most prominent in non-white decedents (OR = 11.6, $p<0.001$, 95%CI = 3.1-43.2) and in male suicide decedents (OR = 2.82, $p<0.001$, 95%CI = 1.6-4.9). We subsequently removed overdose suicides from our sample to eliminate deaths where opiates may have been used strictly as a method of suicide. After this correction, the increase in opiate prevalence among suicide decedents became slightly more pronounced (OR = 2.7 $p<0.001$, 95%CI = 1.5-4.6). Conclusion: The presence of opiates in the blood of suicide decedents more than doubled from 2006 to 2017, particularly in the most recent years and most prominently in males and non-white decedents. These results suggest that opiates are playing an increasing role in completed suicides, even outside of overdoses. Increased vigilance and awareness for suicidality is warranted among both opiate prescribers and users. The study was supported by Dr. Nestadt's NIMH Training Grant (T32 MH014592-40).

No. 217

Outcomes of Universal Screening for Suicidality in Medical Outpatient Clinics

Poster Presenter: Dewey Scott Murphy, M.D.

SUMMARY:

As part of standard practice in the outpatient setting, the nurse asks whether a patient has had thoughts of harming self or others. The aim of our study was to determine whether this question was addressed by physicians after a patient had said "Yes" when asked by nursing, and to what extent there was follow-up planning when patients indicated they had suicidal ideation. Luoma et al. (2002) found that around one-third of patients who died by suicide had contact with a mental health provider in the prior month and around one-half of them had contact with a primary care provider in the prior month. These points of contact represent opportunities to assess patients for safety and intervene to prevent suicide attempts. Some providers have concerns that asking about or addressing suicidal ideation could cause the adverse outcome of increasing suicide rates, simply by bringing up the topic. Crawford et al. (2011) found evidence that screening for suicidal ideation does not increase the likelihood of subsequent suicidal ideation. Norris et al. (2012) note that, in spite of insufficient evidence supporting routine suicide screening for all patients, screening patients with risk factors leads to better treatment and management. Vannoy and Robbins (2011) examined 1776 primary care cases and found that, among 128 patients who screened positive for depression, suicidality was discussed in only 13 cases (11%). In our study, we performed a chart review of 246 patient encounters from a wide variety of outpatient clinics in Huntington, WV, including internal medicine, pediatrics, family medicine, surgical specialties, and psychiatry. These encounters were selected for patients having answered "Yes" when asked about thoughts or self- or other-harm at intake. Based on this review, we determined that physicians documented further exploration of suicidal ideation in around half of the cases, with significant variation between specialties. When patients confirmed suicidal ideation to the physician, further planning (e.g. ER, inpatient admission, education, etc.) was documented only around 70% of the time. Regression analysis revealed that the only significant predictive factor for physicians following up on suicidal ideation was the presence of a depressive disorder in the patient's chart. We

determined that these gaps could be addressed by improving communication between nursing staff and physicians and providing better education to providers in all specialties on assessing and managing suicide risk.

No. 218

SKA2 Methylation: Role of Genetics in Suicide

Poster Presenter: Dharminder Singh
Co-Author: Abdolreza Saadabadi, M.D.

SUMMARY:

Suicide is a complex multifactorial behavioral phenotype influenced by hereditary qualities and environmental factors. Various family studies have shown familial conglomeration of suicidal behavior. Most studies have demonstrated a higher rate of suicidal behavior in relatives of suicide victims or attempters contrasted with relatives of non-suicidal controls. Studies have found greater than 50% increase in the risk for suicidal ideation or attempt in offspring of depressed mothers who had attempted or contemplated suicide relative to offspring whose mothers had never attempted suicide. Family studies support a genetic component of suicidal behavior and many genetics markers have been implicated in suicide. SKA 2 gene has been discovered to be suppressed via methylation in the brains of patients committing suicide and predicted suicide behavior due to stress with approximately 80 percent accuracy. SKA 2 gene is located on Chromosome 17 of the human genome. SKA2 gene encodes a protein called SKA 2 known as Spindle and Kinetochore Associated Complex, which is responsible for anaphase in mitosis by regulating chromosomal segregation. SKA 2 is hypothesized to have effects on suicide through dysregulation of the HPA axis in response to stress. In this article we will review the pathophysiological and psychological basis of SKA2 gene in Suicide and implications of future genetic testing using SKA 2 as a biomarker for suicidal behavior.

No. 219

Suicide Attempts, Psychopathological Disorders Associated in People Assisted in a Ward of a General Polivalent Hospital in Buenos Aires, Argentina

Poster Presenter: Edith Serfaty

SUMMARY:

Suicide behavior is a disorder of multiple rough edges in which several factors are involved, which is framed within agressive behaviors. This research was performed in order to obtain an insight into this distressing condition. Objetive: To study the characterization of suicidal behavior in patients both sexes attending the War of Hospital Dr Alejandro Posadas,in Buenos Aires Province, due to a suicide attempt. Materials and Methods : 230 people were examined in the War and in the Psychopathological Servive, due to a suicide attempt, 200 entered in the study and 30 could not do so not being eligible. Three informed consent were used, two belonging to the Hospital Ward and the third one to be completed by the psychiatry service. A data base was created, as well as the statistical analysis. Results It was examined by psychiatrist, 82 males and 118 females, They had antecedents of suicidal behavior in brothers, mother or father. A connection was found between those patients who , committed suicide attempts and the diagnoses of borderline personality disorder, anxiety, severe depression, bipolar and schizophrenia disorders facilitating access to patients in order to perform an early diagnoses and treatment would be a way of avoiding the aggressive behavior relative to the suicide attempt.

No. 220

Association of Suicidal Ideation With Metabolic Syndrome and Its Components in Adults: A Nationally Representative Sample of Korean Population

Poster Presenter: Jeong-Kyung Ko
Co-Authors: Young-Hoon Ko, Kyu-Man Han, Cheolmin Shin, Jae-Hon Lee, M.D., Ph.D., Changsu Han, Yong-Ku Kim

SUMMARY:

Background: A substantial number of studies suggests that depression may be associated with metabolic syndrome (MetS) which refers to the simultaneous presence of impaired glucose tolerance, dyslipidemia, hypertension and obesity. There is controversy, but several researches have shown an association between low cholesterol levels and increased suicide risk. The aim of this study was

to investigate the associations between depression, suicidal idea and MetS in addition to present association between the individual MetS components and suicidal idea. Methods: This study conducted using cross-sectional data for 5,976 people who aged over 19 years older collected by the 2014 nationally representative sample of Korean National Health and Nutrition Examination Survey (KNHANES). The associations between depression and Mets and between suicidal idea and Mets were estimated after adjusting for related factors using multivariable logistic regression analysis. In this study, the definition of depression was divided into following two categories: i) 10 or above on the Patient Health Questionnaire-9 (PHQ-9) score; ii) prior diagnosis of depression by a physician. Results: There was no significant association between MetS and depression after adjusting for age and gender. (PHQ-9 ? 10 and prior diagnosis of depression) (PHQ-9 ? 10: odds ratio [OR] = 1.17; 95% confidence interval [CI] = 0.92 - 1.48, p > 0.1; prior diagnosed depression: OR = 1.18; CI = 0.76 – 1 86, p > 0.1). However, suicidal ideation was considerably associated with MetS after adjusting for age and gender (OR = 1.53; CI = 1.04 – 1.23, p = 0.03). Suicidal ideation was also associated with the individual MetS components including high triglyceride (OR = 0.54; CI = 0.39 – 0.76, p < 0.001) and high fasting glucose level. (OR = 0.726, CI =0.48-0.96, p = 0.028) Limitations: This study based on a cross-sectional study design with few adjusting factor. Lack of a standardized objective measure for depression may limit our results. Conclusions: In this study, adults with metabolic syndrome were more likely to have suicidal idea in Korean adult. Several previous studies have suggested an association between low cholesterol levels and increased suicide risk, however the findings in this study showed different results. Specifically, high triglyceride, high fasting glucose level and obesity were associated with suicidal ideation in adults. Our study provide an implication that managing these components of MetS may help reduce suicidal risk in adults.

No. 221

A Spanish Study of Patients With a Background of Substance Use Disorder After Suicide Attempt

Poster Presenter: Jose Maria Portes
Co-Authors: Jesus Gomez-Trigo Baldominos, Manuela Perez Garcia, Alfonso Mozos Ansorena, Cecilia Blanco Martinez, Monica Mourelo Farina, Manuel Arrojo Romero, Eduardo S. Paz Silva, Mario E. Paramo Fernandez

SUMMARY:
Background: The risk of suicide in patients with Substance Use Disorder (SUD) is six times greater than in the rest of population. Describing the type of patient with SUD who performs suicide attempt is essential to identify risks within this population. In previous studies, the highest prevalence of the female gender has been found within the population with SUD that performs suicide attempts. Likewise, affective disorders and personality disorders are the comorbid pathologies that appear most frequently in suicides and suicide attempts. The objective of the study is to collect the main characteristics of the type of patient requiring urgent hospital care, with history of SUD, comparing with those who have not got this disorder in their history. Methods: prospective study was conducted with sample n=88 subjects. Risk factor to be analyzed: toxic substance use. Time period: one year. SPSS computer statistical pack was used. A data collection protocol was applied, with different variables. Results: Our sample sociodemographic profile was a woman (66.7%), single (69.7%), living alone (45.5%), with primary studies (57.6%) and unemployed (51.5%). The most common comorbid psychiatric diagnoses were personality disorders (47.06%) and affective disorders (25.53%). 39.4% of patients requiring entry into the Intensive Care Unit, had history of SUD versus 23.52 who did not. Conclusions: From the results obtained, relationship between SUD and other psychiatric pathologies, especially personality disorders, can be extracted. Results in parameters such as planning and possibility of rescue in suicide attempts of our study, show a potential relationship between the impulsive character in personality disorders. Identifying suicide risk factors in the population with SUD by describing patients who perform autolytic attempts that need hospital care is a fundamental pillar to focus psychiatric attention in certain sectors of users of devices specialized in addictions disorder, in order to manage the supervision and surveillance in patients that fit the results obtained in this study, described in the profile patient of our sample.

No. 222

Suicide Attempt in African Americans After Hospitalization in First-Episode Psychosis: A Case Report and Literature Review

Poster Presenter: Khurram Saleem Janjua, M.D.
Co-Authors: Kelvyn Rafael Hernandez Tejada, M.D., Tresha A. Gibbs, M.D.

SUMMARY:

Patient is a 22 years old African American (AA) male, adopted, recently graduated college, currently unemployed, recently discharged from inpatient unit after presenting with 6 months of paranoid ideation, depressed mood, functional decline, and self-isolation. He reported a history of 2 prior suicidal gestures. He was initiated on an oral antipsychotic and antidepressant with good effect. He was discharged with a diagnosis of schizophrenia. Within 2 weeks of discharge, patient became acutely suicidal following a failed attempt to go on a job interview. He overdosed on his psychiatric and antihypertensive medications. He was taken for medical evaluation where he was re-admitted to the psychiatric unit. Introduction: The post hospitalization period is high risk period for suicide, particularly in patients with mental disorders. Irrespective of diagnosis, completed suicide rates are at least 10-20 times greater in patients with psychiatric diagnosis within 90 days of discharge than that of patient without mental disorder diagnosis. First episode psychotic patients are at particularly high risk with 1/10 attempting suiciding within 1 year of hospitalization. Studies have found that predictors of suicide attempt include history of suicide attempt, severe depression, history of antidepressant treatment, and alcohol and substance abuse. According to NSAL, there is a 4% prevalence of suicide attempts among the general population of African Americans in US. Among African Americans, limited information is known about suicide attempts post hospitalization. Methods: In depth literature search conducted to explore terms such as suicide, first episode, psychosis, hospitalizations, race, ethnicity, and black. Data/Results: Few studies focus on the ethno cultural aspects of suicidality in the AA and Latino first episode psychosis patient particularly post hospitalization. Discussion/Conclusions: Clinicians should be aware of the high risk of suicidal behavior in the post hospitalization period, particularly the first 90 days. Among African Americans, particular attention should be paid to hopelessness, depression and locus of control. Factors such as income may not be so pertinent risk. Culturally sensitive interventions are important with awareness of protective factors such as religious coping styles.

No. 223

Blue Monday Is Real for Suicide: A Case-Control Study of 188,601 Suicide Victims

Poster Presenter: Kyoung-Sae Na, M.D.
Co-Authors: Seong-Jin Cho, Seo-Eun Cho

SUMMARY:

Objective: Many studies have reported that suicides tend to occur on Mondays. However, owing to a lack of controls, conclusive findings on the potential effects of a day of the week on suicides have been lacking. Method: We analyzed public data for causes of death from 1997 to 2015 in the Republic of Korea. Accidental death was used as a control group. The probability of suicide on each day of the week according to age group was calculated. Results: A total of 377,204 deaths (188,601 suicides and 188,603 accidental deaths) was used. The frequency of suicide was highest on Monday and decreased throughout the week until Saturday. Accidental death was highest on Saturday and showed no variations according to weekday. For people in their teens and 20s, the probabilities of suicide on Monday were 9% and 10% higher, respectively, than those on Sunday. As age increased, the differences in suicide probability according to the day of the week were attenuated. Conclusions: The so-called “Blue Monday” effect is real, particularly for people in their teens and 20s. Suicide prevention strategies that aim to attenuate the burden and stress of Mondays should be planned.

No. 224

Treatment Utilization Before Suicide in Patients With Traumatic Brain Injury

Poster Presenter: Mansi Seth Chawa, M.D.
Co-Authors: Rebecca Rossom, Deepak Prabhakar, M.D., M.P.H., Edward Peterson, Cynthia Di Giandomenico, M.D., Christine Lu, Beth Waitzfelder,

Ashli Owen-Smith, Arne Beck, Gregory Edward Simon, M.D., L. Keoki Williams, Frances Lynch, Brian Ahmedani

SUMMARY:
Background Traumatic brain injury accounts for approximately 50,000 deaths in the United States annually. Our previous study found that traumatic brain injury (TBI) increases risk of suicide by more than 8-fold, even after adjusting for mental health conditions, age, and gender. Suicide risk has been observed to remain chronically elevated and could persist for 15 years or more after TBI. The objective of the current study was to determine variations in general health care visit patterns for patients with TBI who die by suicide and compare them to matched controls (patients with TBI who did not die by suicide) in a large diverse US population. Methods This is a study from Mental Health Research Network that involves data from eight geographically diverse health systems across the US. We used electronic health record data to assess multiple healthcare factors within the year before an index date (the date of death for cases and a matched date for controls). Official state mortality data were linked to health system records. Conditional logistic regression was used to compare variations in visit patterns among cases and controls. Additional analysis for assessing demographic and other behavioral health factors was also conducted. Results A total of 61 cases with TBI who died by suicide were compared to 75 matched controls. The more frequently patients had clinic visits for their TBI, the less likely they were to die by suicide (aOR=0.29, 95% CI: 0.12-0.68). However, patients who had a more remote clinic visit were less likely to die by suicide than those with a more recent clinic visit (aOR=0.93, 95% CI: 0.89-0.98). Conclusions Patients with TBI who died by suicide tended to visit clinicians less frequently than patients with TBI who did not die by suicide. However, the most recent visit before the index date was closer for patients who died by suicide than those who did not. This indicates that clinicians have an opportunity to intervene and assess risk factors prior to patients ending their life. While this study helps in identifying variations in visit patterns for TBI patients, future studies with larger sample size are required to confirm these findings.

No. 225

Differences in Health Care Use in the Year Prior to Suicide Death: A Population-Based Case-Control Study

Poster Presenter: Megan Chock

SUMMARY:
Background: Suicide is the 10th leading cause of death in the United States. Many studies describe suicide decedents' healthcare contact in the year before death, but few have compared healthcare use between suicide decedents and similar others. This population-based case-control study examines healthcare use of suicide decedents and age- and sex-matched controls in a diverse U.S. population. Methods: Suicide decedents who were members of a large health maintenance organization from January 1, 2008 to December 31, 2014 were identified using mortality data. Each case was matched to three controls. Healthcare use in the year before suicide death was classified by setting (inpatient, outpatient, emergency, and home visits) and visit type (mental health or non-mental health reason, primary or non-primary care). Demographic data including the Charlson Comorbidity Index (CCI) were collected for each subject. Matched analysis via conditional logistic regression was used to explore the relationship between risk of suicide death and frequency and type of visits in each quarter prior to death, and to test for associations between suicide death and other factors. Results: The analysis included 1221 cases and 3663 age- and sex-matched controls (mean age 52.8, 76.6% male). Cases were more likely to have had a mental health diagnosis (62.1% vs 20.1%, $p<0.01$) and a higher level of physical comorbidity (CCI 1.3 vs 0.9, $p<0.01$). Cases and controls did not differ in having had at least one visit in the past year (95% CI 0.9-1.7), but cases had significantly more visits overall (mean 17.5 vs 8.0, $p<0.01$) and for mental health reasons (mean 0.6 vs 5.5, $p<0.01$). Cases were more likely to have had inpatient (95% CI 1.3-1.9) and emergency (95% CI 1.3-1.6) visits for non-mental health reasons. Cases were not more likely to have had outpatient non-mental health, homecare or other visits. Cases, but not controls, showed an increasing frequency of healthcare use closer to death (5.7 visits 0-3 months before death vs 9-12 months before death) in

higher-cost, non-primary care settings (emergency, inpatient, and outpatient specialty care). Conclusion: Suicide decedents have distinct patterns of healthcare use before death. Patients with a mental health diagnosis and more physical comorbidities with an increasing frequency of healthcare visits, especially in inpatient and emergency settings, should be considered at higher suicide risk. Suicide prevention has focused on primary care and mental health screening. The vast majority of cases and controls were not screened using the standardized instrument available to providers. This study shows that specialty care providers have a key intervention role as suicide decedents appear to increase outpatient non-primary care visits for mental health and non-mental health reasons. With electronic health records, we can flag patients with these patterns of increased healthcare use for suicide prevention in all care settings.

No. 226

Factors Associated With Outpatient Treatment Compliance of the Suicide Attempter Visiting Emergency Center

Poster Presenter: Min-Je Lee

SUMMARY:

Objective: The purpose of this study is to research factors which affect the compliance of psychiatric outpatient follow-up treatment to the suicide attempting patients in the emergency room. Methods: We reviewed the medical records of 346 suicidal attempters who were discharged from emergency center of the Chungbuk National University Hospital from January 1, 2014 to December 31, 2015. They were divided into two groups: patients who came for OPD follow up treatment and patients who did not. We gathered a data including psychosocial characteristics and factors related to suicide and factors related to psychiatric treatment. After classifying the patients, we compared and analyzed the factors which could influence each group. Results: After being discharged, 233 patients did not show up for OPD follow up treatment and 113 patients came for OPD follow up treatment. There were significant differences between the two groups in the drunken status, lethality of Suicide Attempt, time of presentation to ER, and OPD waiting time. But, sociodemographic characteristics, medical condition did not influence the outpatient follow up compliance. Conclusion: There were significant differences in factors that affect the outpatient follow up compliance between the two groups. Additional research is required to increase outpatient follow up compliance.

Physician Suicide: A Silent Epidemic

Poster Presenter: Omotola O. T'Sarumi, M.D.
Co-Authors: Ayesha Ashraf, M.D., Deepika Tanwar, M.D., Adrienne Hicks, M.D.

SUMMARY:

Physician Suicide: A Silent Epidemic Omotola T'Sarumi, MD, Ayesha Ashraf, MD; Tanwar Deepika, MD; Adrienne Hicks, MD; MD; Eric Rubin, MD Objective: Suicide among physicians has received more publicity as studies report rates higher than that of the general population or among any other profession. In the US an estimated 1 physician dies every day from suicide, with a yearly total of about the equivalent of an entire medical school. Risk factors associated with higher rates of suicide among doctors have been identified, but little has been learned about prevention. We review here reports describing the occurrence and interventions to prevent physician suicide. Method: We reviewed reports mainly in MEDLINE and Pubmed published in the last 10 years. Results: Doctors have the highest suicide rate of any profession. The suicide rate among physicians is 28-40 per 100,000, more than double that in the general population. Female physicians attempt suicide far less often than women in the general population, yet their completion rate equals that of male physicians and, thus, far exceeds that of the general population (2.5-4 times the rate by some estimates). The most common psychiatric diagnoses among physicians who completed suicide were mood disorders, alcoholism, and substance abuse. In a Facebook-based survey of 2106 female physicians , 50 % reported meeting criteria for a mental disorder but were reluctant to seek professional help due to the fear of stigma. The most common means of suicide by physicians is by medication overdose and firearms. There is little consensus on effective means of preventing physician suicide. Fear of stigma is a

major obstacle for treatment. Some studies question the effectiveness of physician health programs (PHP). The most promising intervention reported was a web-based CBT program which was associated with reduced suicidal ideation among medical interns. Conclusions: Suicide amongst physicians is an under-recognized public health concern. To date, treatment interventions have not lowered the rates of physician suicide. To reduce the number of physicians taking their life, fear of stigma and other risk factors have to be addressed through more research aimed at effective and early intervention.
Key words: Physician; Suicide; Prevention

No. 228

Risk of Suicide Death in Individuals With a History of Suicide Attempt(s)

Poster Presenter: Simran Singh Chawa, M.D.
Co-Authors: Deepak Prabhakar, M.D., M.P.H., Brian Ahmedani

SUMMARY:

Background: According to the Center for Disease Control and Prevention (CDC), in the U.S., from 1999 to 2014, the age-adjusted suicide rate increased from 10.5 to 13.0 per 100,000, furthermore, the rise has been the greatest since 2006. Previous suicide attempts are understood to be one of the significant risk factors for completed suicide. The objective of our study is to examine population level data collected from the U.S. population examining attempted suicide as a risk factor for completed suicide. Methods: We conducted a case-control study involving Mental Health Research Network (MHRN), a consortium of 13 learning healthcare systems, 8 of which participated in the study. The study involved a total of 2,674 Case individuals who died by suicide from 2000-2013. Controls were selected in a 100:1 ratio for a total of 267,400 individuals who were matched by site and time period. Results: Male victims of suicide death had an OR of 160.7 to have had previous suicide attempts, compared to females who had an OR of 206.9. Individuals who were diagnosed with one of the major psychiatric conditions had lower odds (34.0) of previous suicide attempts compared to individuals who weren't diagnosed (405.7). The OR of previous suicide attempt in individuals who died by suicide was 814.3 for those aged 10-14, 45.4 for those in age group 15-24, 197.9 for those aged 25-44, 197.5 for ages 45 to 64, and 288.6 for those older than 65. For individuals who were diagnosed with Major Depression, the odds of having a previous attempt were 27.4 compared to 314.7 for those who didn't have the diagnosis; for bipolar disorder, the odds were 14.2 vs. 151.5 for those diagnosed vs. not. For patients with drug abuse, the odds were 12.3 for those with diagnosis, vs 165.5 for those without diagnosis. For patients with schizophrenia, the odds were 21.3 vs 142.8. For those with anxiety, the odds were 29.8 vs 187. For those with ADHD, the odds were 51 vs 152.5. Conclusion: Females who died by suicide had a higher chance of previous suicide attempts compared to males. The risk of death by suicide was high across all age groups, but the odds were especially high for individuals on the opposite end of age spectrum. Mental heath diagnosis was associated with a lower risk of suicide death in individuals with prior attempts. Our study should help quantify the risk of suicide in individuals with history of suicide attempts. Future studies should investigate care utilization patterns among those who had a suicide attempt prior to death by suicide.

No. 229

Are Guns and Suicide Related?

Poster Presenter: Simrat Sarai
Co-Authors: Hema Mekala, Steven B. Lippmann, M.D.

SUMMARY:

Shooting oneself to death is nearly twice as common as gun-related homicides in the United States, and the lethality of a suicidal gunshot is extremely high. There are about 20,000 firearm-induced suicides each year, over 50 each day. Suicide among veteran populations is at epidemic proportions. Having a gun and ammunition readily accessible in the home is a major factor that facilitates completed suicide. Most firearm-related attempts result in a fatality. Even though most suicidal impulses are intense, they commonly are brief in time duration. Definitive action, especially by the family, is important during that period. Most of the people who try to kill themselves, but survive, do not later end-up committing suicide. Having a firearm easily available is closely associated an increased risk of suicide; just removing access decreases dangerousness. Anyone with ready access to a gun and ammunition is even

more likely to commit suicide than those who do not have ammunition also available. Doctors should stress a recommendation that firearm availability be removed from anyone experiencing depression, acute grief, suicidal thoughts, substance abuse, high impulsivity, or those with psychiatric and/or neurologic ailments. Physicians should also provide guidance about safe storage; this means that guns and ammunition are to be locked-up in separate locations and that firearms remain unloaded. Just following such safer weapon storage strategies greatly reduces gun-shot death by suicide, impulsive acts, and for accidents.

Characteristics Affecting Suicide Method: Based on the Analysis of Suicide Mortality Data in One District of Seoul

Poster Presenter: Sungjune Bae

SUMMARY:

Objectives Suicide has become the most serious public health problem in Korea. In this study, we investigated the demographic and social characteristics affecting the suicide methods. Methods Data of suicide deaths reported from 2008 to 2014 in Yeoungdeunpo-gu, Seoul were reviewed and analyzed. Demographic data and characteristics including age, gender, education level, the time of death, the place of death, and the method of death were examined. The variants of each suicide death method were compared using Chi square and Fisher's exact test. Spearman correlation analysis and logistic regression analysis were performed, respectively. Results More than half of suicide victims (68.4%) were male. The most frequent suicide deaths were in the spring (March to May, 29.1%), during the afternoon (noon to 6:00 pm, 33.4%). Hanging(59.4%), jumping (17.0%), and gas intoxication (8.9%) were the most frequent suicide methods. The risk of drug intoxication was increased in old age, out of residence, while that of gas intoxication was associated with male, young age, winter. The risk of hanging was related to low education level and the risk of drowning was increased in female, old age and summer. Conclusion The suicide method was associated with age, gender, time, season.

Case Management Plus Second-Generation Long-Acting Injectable Antipsychotics as Preventive Strategy of Suicide Among People With Severe Schizophrenia

Poster Presenter: Sylvia Díaz

Co-Author: Juan J. Fernandez-Miranda

SUMMARY:

Background Adherence to treatment of people with severe schizophrenia is important to reach clinical and rehabilitation goals and to prevent suicidal behaviour. The purpose of this study was to know the retention in treatment of people with severe schizophrenia, suicide rates among them and factors related (standard treatment vs comprehensive case managed and oral vs long-acting injectable medication) Methods 8-year prospective, observational, open-label study of patients with severe schizophrenia (GCI-S>=5) undergoing community based, comprehensive, case managed treatment in Gijon (Spain) (N=200). Assessment included the Clinical Global Impression severity scale (CGI-S) and the WHO Disability Assessment Schedule (WHO-DAS). And also medications prescribed, laboratory tests, weight , adverse effects reported, hospital admissions and reasons for treatment discharge., including deaths by suicide, were recorded. Results CGI-S at baseline was 5.9(0.7). After eight years 42% of patients continued under treatment (CGI-S= 4.1 (0.9); p<0.01); 37% were medical discharged (CGI=3.4 (1.5); p<0.001) and continued standard treatment in mental health units; DAS decreased in the four areas (self-care and employment p<0.01; family and social p<0.005) in both groups; 7% had moved to other places, continuing treatment there; 10% were voluntary discharges. Twelve patients died during the follow up, four of them by suicide (2%; suicide rates among people with schizophrenia in standard treatment in Spain between 5-10%). All patients had their own case manager, mainly a nurse (89%). 65% of all patients were treated with second-generation long-acting-injectable antipsychotics (risperidone, paliperidone and aripiprazol). Among them, there was higher retention (4 vs 16 patients voluntary discharges; p<0.01) and less suicides than patients with oral antipsychotics (1 vs 3 patients).

Conclusions Retention in treatment of patients with schizophrenia with severe symptoms and impairment in a comprehensive, community based, case managed programme and treated with second generation long-acting antipsychotics was really high and seemed to be useful to decrease the high rates of suicide among them. Both treatment characteristics (case management and 2G-LAI antipsychotic use) helped to improve treatment compliance and suicide rates compared with standard treatment and oral medications.

No. 232

Low Conscientiousness and Less Motivation and Competence in ADHD Patients: Their Relation to Their Well-Being

Poster Presenter: Javier Irastorza

SUMMARY:

Adult ADHD are characterized by strong heterogeneity in cognitive underperformance with multiple cognitive memory pathways, inhibitory control, delay aversion, decision making, timing, response variability and emotional regulation. Motivationally based ADHD models shift the focus from inattention to impairments in motivation and offer an alternate view for difficulties affecting task completion in people with ADHD. Personality dimensions (NEO-PI-R) associated to them are: lower Agreeableness, Conscientiousness and Extraversion and higher Neuroticism. Based on a cross-sectional adult ADHD outpatients study, authors observe a correlation between conscientiousness and inattent subtype. Therefore the authors expose some ideas about competence components and implicit and explicit motivational systems. ADHD patients may have associated learning disorders; they may be more creative and practical and usually have less analytic thinking. They have less metacognition and motivation, even more in the long time. A good way of increasing motivational competence will help people access their implicit motives and will promote goal specific competences and their well-being.

Study of Factors Affecting on Evaluation of Sex Offenders' Criminal Responsibility

Poster Presenter: Jinwoo Kim

Lead Author: Jonghuk Choi
Co-Authors: Seyoung Oh, Jangwon Lee

SUMMARY:

Objective: This study analyzed factors affecting feeble-mindedness or insanity following a forensic evaluation for sex offenders, and to present a scientific basis that can provide practical assistance on a responsibility evaluation of sex offenders. Methods: This study analyzed retrospectively 180 mental appraisals on sex offenders among mental appraisals documented by one psychiatrist from June, 2012 to December, 2015 at the National Forensic Hospital. Results: Of the 180 mental appraisals, 123 people (68.3%) were found to be feeble-minded or insane, and 57 people (31.7%) were considered to be sane, i.e., competent to take responsibility. The two groups were different in IQ, occupational & marital status, victim numbers, psychiatric diagnosis, and sex offender characteristics, such as violence and intrusiveness. After evaluating the influence of variables that showed significant differences between the two groups on a responsibility assessment, sex offenders with fewer invasive sex offenses (OR=1.763, $p<0.05$), lower IQ (OR=1.031, $p<0.01$), lower numbers of victims (OR=1.349, $p<0.05$), and higher number of mental illnesses (OR=0.507, $p<0.05$) were more likely found to be feeble-minded or insane. Conclusion: This study indicates that criminal responsibility may be intact in repeat sex offenders who commit invasive sex crimes, such as rape, and is without intellectual disability compared to other kinds of sex offenders. Subsequent research will be needed to improve the objectivity and reliability of mental appraisals on sex offenders in the future. This study have no financial conflicts of interest

No. 234

Aging as a Long-Term Resident of an Intermediate Security Forensic Hospital

Poster Presenter: Vera Prisacari

SUMMARY:

Patients found Not Guilty by Reason of Mental Disease or Defect (NGRMDD) are hospitalized for some period of time following acquittal. These individuals often spend more time institutionalized than their counterparts convicted of the same

offense. Insanity acquittees are civilly committed without a specified maximum release date and are integrated into the community only when determined safe. This case study involves a 69 year old patient who was found NGRMDD on murder charges. He has resided in a forensic hospital for over 20 years during which period his psychiatric diagnoses resolved and he is no longer taking any psychotropic medication and as such provides an example of aging within a forensic institution. While the patient has struggled emotionally with lifestyle restrictions, this poster shows that it is possible to meet strict dietary requests, exercise needs, and micronutrient requirements over long term and age healthily in medium security forensic hospital.

No. 235

New Rulings on Involuntary Psychiatric Treatment

Poster Presenter: Viviana Alvarez Toro, M.D.

SUMMARY:

Historically, psychiatry has often been portrayed as a paternalistic field where people are often forced into treatment in traumatic ways. Nevertheless, many laws and regulations have been passed over time to strengthen and reaffirm individual autonomy. Several landmark cases, particularly Washington v. Harper, Riggins v. Nevada, and Sell v. United States, have been instrumental in shaping the legal standards for involuntary administration of psychiatric medications at a federal level. These cases set the stage for two recent cases, DHMH v. Kelly (2007) and Allmond v. DHMH (2016), that have been determinative in influencing the practice of psychiatry in Maryland. By taking these cases into account, this poster seeks to highlight the history of involuntary administration of medications to the mentally ill. It will also target the ongoing controversies that this topic continues to raise across the country in both an inpatient and outpatient setting. This is particularly significant for states such as Maryland, where assisted outpatient treatment still does not exist.

No. 236

Mental Health and the Criminal Justice System: An Ethical Imperative for Reform

Poster Presenter: Zain Khalid, M.D.

SUMMARY:

Incarceration rates have soared in the US since the 1970s. At present the US incarcerates approximately 700 per 100,000 of its citizens, more than any of its liberal democratic peers. This expansion in the penal population has engendered extensive investigative interest and many contributory factors have been noted in literature, including the War on Drugs, mandatory minimum and three strike laws, an adversarial policing culture and deinstitutionalization of the mentally ill. These policy measures have often been informed by beliefs and perspectives that prioritize individual agency over structural and socioeconomic determinants of crime. The result has been a widening of preexisting socioeconomic and health disparities among vulnerable populations such as the mentally ill, the poor and racial and ethnic minorities. Mental health problems are in fact not only disproportionately prevalent among the incarcerated, they are also frequently exacerbated by incarceration. Substance abuse problems which affect approximately half of state and federal prisoners are frequently under-treated in correctional settings. The underutilization of medication assisted treatments for opioid use disorder for example is a particularly concerning instance of such under-treatment. Excessive incarceration has also been show to have significant deleterious impacts on the mental health of the communities overrepresented in the correctional system. A recent Bureau of Justice Statistics Report on Mental Health Problems reported by Prisoners and jail inmates noted 1 in 7 state and federal prisoners and 1 in 4 jail inmates as reporting experiences that met the criteria for severe psychological distress. Negative effects of parental incarceration on families, particularly children's mental health and subsequent delinquency are also well documented. In recognition of these alarming realities that attend the present carceral system and it's association with mental health challenges, this review examines the role psychiatrists particularly those involved in correctional settings can play in stimulating and catalyzing criminal justice system reform, and the ethical imperative that bears on it. It focuses in particular on advocacy for more equitable provision of mental health treatment, and summarizes the evidence for the potential salutary effects of decarceration policies, community

corrections programs, diversion of the mentally ill and those with substance abuse problems away from traditional criminal justice system as via Veteran treatment courts as well as recent innovations such as forensic community treatment teams to reduce recidivism, facilitate re-entry and address structural determinants of crime.

No. 237

Major Depressive Disorder Secondary to Hyperparathyroidism

Poster Presenter: Ahsan Syed Khalid, M.D.
Co-Author: Melissa Martinez, M.D.

SUMMARY:

Major depressive disorder (MDD) has many causes and ruling out primary medical causes is essential for determining treatment options and management. We present a case of a 64 yo female with multiple medical comorbidities and history of treatment refractory MDD (with positive pan-SIGECAPS). The patient was eventually found to have increasing calcium levels and symptoms of hyperparathyroidism with a parathyroid adenoma. Following removal of the adenoma, the patient showed remarkable improvement in depression symptoms both subjectively and objectively, as reflected in PHQ-9 scores. It is important for physicians to be vigilant, recognize potential medical causes of MDD, and treat underlying etiologies in an effort to provide optimal patient care.

No. 238

Comparison of Recovery Times From Neuroleptic Malignant Syndrome: Typical Versus Atypical Antipsychotics

Poster Presenter: Elise Griffin
Co-Authors: Andrew J. Powell, M.D., Suporn Sukpraprut-Braaten

SUMMARY:

Comparison of Recovery Times from Neuroleptic Malignant Syndrome: Typical vs Atypical Antipsychotics Co-authors Suporn Sukpraprut-Braaten, MSc, MA, Ph.D., Andrew Powell, M.D. Abstract Background: Neuroleptic malignant syndrome (NMS) is a diagnosis of exclusion caused by taking dopamine blocking drugs and resulting symptoms of fever, muscle rigidity, mental status changes and autonomic instability that can end in fatality. This study compared the recovery times and treatment modalities of patients with NMS who were taking atypical antipsychotics versus typical antipsychotics. Methods: Data for this meta-analysis study was extracted from several different medical databases. Keywords used included neuroleptic malignant syndrome (NMS), atypical antipsychotics and NMS, typical antipsychotics and NMS, second generation antipsychotics and first generation antipsychotics were used for article search. Over 1,600 articles were found. From the pooled data obtained, after exclusion criteria were applied, we compared time to recover from NMS between patients taking typical versus atypical antipsychotics, as well as comparing which treatment modalities contributed to speed of recovery. Results: This analysis included 48 patients. The atypical group included 22 patients comprising 15 males and 7 females having an average age of 41.7 years. The typical group included 26 patients comprising 11 males and 15 females having an average age of 30.8 years. Patients with NMS in the atypical group took a shorter time to recover (mean=9 days) than patients in the typical group (mean=28 days). There was a slight difference in recovery time between single (mean=23 days) vs. multiple (mean=19 days) NMS treatment modalities. Patients without any treatment took an average of 6 days to recover. Patients with a combination of 3 treatment modalities took an average of 61.5 days to recover. The patients treated with Amantadine alone took an average of 4 days to recover. Conclusion: Subjects in the atypical antipsychotic group were shown to take less time to recover from NMS than those in the typical antipsychotic group. Treatment with Amantadine alone led to shorter recovery time but was not shown to significantly differ from using no treatment. Patients using a combination of 3 or more treatment modalities took a longer time to recover than any other treatment modality group. Although data shows overall that patients being treated with 2 or more treatment modalities recovered faster than patients treated with only one modality, the data suggests that recovery time with multiple treatment modalities would have been shorter if the 3+ treatment data weren't included. These results suggest that if treating NMS with

multiple modalities that the number of treatments be limited to two.

No. 239

Escitalopram-Induced Hypoglycemia? A Case Report and Review of Literature

Poster Presenter: Mariana Mello
Co-Authors: Juliano Victor Luna, M.D., Lourdes Thalita Meyer de Andrade Cavalcanti, M.D.

SUMMARY:
A 24-year-old woman sought psychiatric outpatient care in a general hospital due to a 7 month history of anxiety and panic disorder symptoms. The patient had been diagnosed with type 1 diabetes since the age of 7 and was currently using regular insulin subcutaneous pump. Escitalopram 10 mg was started and the patient had symptomatic hypoglycemic episodes within the first month of the antidepressant (AD) use. No other causes of hypoglycemia were found. Her endocrinologist lowered insulin doses while escitalopram was maintained. Her glycaemia was stabilized then. Discussion: Anxiety is a common comorbidity in diabetes, some studies have showed that 15 percent of the patients have generalized anxiety disorder and 40 percent have elevated symptoms of anxiety[1].Although there are few studies involving anxiety and diabetes, co-morbidity of these two afflictions may have a significant morbidity, with outcomes such as an increased risk of hypertension, inflammation, and difficult glycemic control[2]. Case reports describe hypoglycemia in patients with diabetes mellitus that use AD, arguing that in an unknown way they could change blood glucose metabolism by an increase in insulin sensitivity that would lead to a higher risk of hypoglycemia. This was associated to AD with higher affinity for the serotonin reuptake transporter. AD use increases almost three times the risk of hypoglycemia, with the need of hospitalization in some cases[2]. On the other hand, some studies showed high levels of inflammatory reactions in patients submitted to stress induction, in a simulation of panic disorder. Chronic cortisol release could contribute to hyperglycemia in these patients. A meta-analysis related anxiety disorders with hyperglycemia, but it's underlying mechanisms were not clarified[2]. There is a possibility that control of anxiety and panic disorder symptoms could low cortisol and systemic inflammation levels, and therefore the need for insulin. Escitalopram direct hypoglycemic effect may also be considered[2]. As the patient used insulin pump, the maintenance of same insulin doses may have resulted in hypoglycemic episodes.

No. 240

Race-Implicit Associations in Mental Health

Poster Presenter: Amalia Londono Tobon, M.D.
Co-Authors: Michael Howard Bloch, M.D., Jerome Henry Taylor, M.D.

SUMMARY:
Background: Implicit biases among healthcare providers can have significant consequences for the care that patients receive. Most of the literature on provider biases has been performed in non-psychiatric medical specialties. Furthermore, there is a dearth of rigorous studies that evaluate disparities in diagnosis and treatment of psychiatric diagnosis. This study aims to gain a greater understanding of implicit racial association among mental health practitioners. In particular, the presence of implicit racial biases among mental health practitioners in regard to (1) psychiatric diagnosis (psychosis compared to mood disorders); (2) medication choice (antipsychotics compared to antidepressants) and (3) provider expectations regarding compliance (compliance compared to non-compliance). Methods: Mental health and other practitioners and trainees were recruited via e-mail and social media to complete an anonymous 25-minute online survey. The online study included demographic questions, exposure to black individuals, and measures of empathy, burnout, and depression, as well as three Implicit Association Tests (IAT) relating to diagnosis, medication treatment, and compliance. Participants were provided with educational material regarding implicit biases at the completion of the study. Result: Initial results from the first 120 providers demonstrated a modest, statistically significant association suggesting implicit biases associating black faces with psychotic (as opposed to mood) disorders, antipsychotic medication (as opposed to antidepressant medications) and non-compliance. We will present the final results from this study at the APA after recruitment is completed in November 2017. These results will include a larger sample size

and secondary analysis of the data to examine correlates of stronger implicit associations. Conclusions: Implicit associations in mental health can affect the diagnosis and treatment of patients. This study highlights the need for ongoing rigorous evaluation of implicit attitudes in mental health. Future research should examine the (1) association between implicit biases and actual physician behavior and (2) examine the ability of educational interventions to reduce implicit biases in health care providers. This study was supported by the American Psychiatric Association/ Substance Abuse and Mental Health Services Administration Minority Fellowship Program.

No. 241

Association of Treatment Response With Obesity and Other Metabolic Risk Factors in Adults With Depressive Disorders

Poster Presenter: Hyungsook Hong
Co-Authors: Young Sup Woo, M.D., Taeyoun Jun, M.D.

SUMMARY:

Association of treatment response with obesity and other metabolic risk factors in adults with depressive disorders Co-Authors Hyungsook Hong, M.D., Young Sup Woo, M.D., Taeyoun Jun, M.D. Background: Available studies indicate that obesity may exert a moderational effect on antidepressant treatment response. The aim of this study was to investigate the relationship between treatment response and metabolic abnormalities amongst patients with depressive disorders in a large naturalistic clinical setting. Methods: A nationwide prospective study was conducted in 18 hospitals in South Korea; 541 depressive patients meeting DSM-IV criteria were recruited. After baseline evaluation, subjects received naturalistic clinician-determined antidepressant interventions. Assessment was performed at baseline and weeks 1, 2, 4, 8, 12, 24 and 52. Treatment response was defined as a Z50% reduction from baseline on at least one evaluation point. Results: In univariate comparison, the patients who showed insufficient response to antidepressant therapy were more likely to be male, unmarried, unemployed, and obese. After adjusting for baseline variables, male sex (OR¼1.82) and obesity (OR¼1.55) remained as were significant variables. Stratification of the subjects into one of three groups, i.e. male, pre-menopausal female and post-menopausal female, revealed that males with concurrent metabolic problems, (i.e. the presence of one or more of hypertension, hyperglycemia, or hypercholesterolemia) had significantly higher risk for insufficient response (OR¼2.32) and, after adjusting for baseline variables, obesity predicted insufficient response in post-menopausal female (OR¼2.41). Conclusions: The presence of metabolic abnormalities in patients with depressive disorders was associated with decreased treatment response to antidepressants. These results underscore the neurobiological relationship between obesity and the central nervous system, and provide empiric evidence supporting stratification of treatment response in depression.

No. 242

Decreased Health-Seeking Behaviors in Depressive Patients: The Korea National Health and Nutrition Examination Survey 2014

Poster Presenter: Hyungsook Hong
Co-Author: Tae-Suk Kim, M.D.

SUMMARY:

Background: The purpose of this study was to investigate the effect of depression on health-seeking behaviors through the large epidemiological study data of the Korean National Health and Nutrition Examination (KNHANES). **Methods:** The 6th Korea National Health and Nutrition Examination Survey (KNHANES VI, 2014), which is a large-scale national survey, was addressed in this study. Patients health questionnaire-9 (PHQ-9) was used to assess the depressive states of the participants. Specialized self-reported questionnaires which include the question about health-seeking behaviors were also performed. To examine the relationship between depression and health-seeking behaviors, a complex sample logistic regression models with controlling for covariates were used. **Results:** There was a significant association between decreased health-seeking behaviors and depression in adults (OR=3.09, 95% CI [2.41, 3.96]). We also found that the association is more strong in men (OR=3.35, 95% CI [2.20, 5.10]) rather than women (OR=2.99, 95% CI [2.28, 3.94]).) Among age groups, young-aged adults (19–44 years old) showed the highest odds

(OR=3.25, 95% CI=2.27–4.90), which suggested that depressive patients had lower health-seeking behaviors than control groups. **Conclusion:** Our findings support an idea that there are significant association between the health-seeking behaviors and depression in Korean population. These results suggest that individuals with decreased health-seeking behaviors would be evaluated with their depressive symptoms.

Transcranial Direct Current Stimulation and Cocaine Addiction: A Double-Blind Placebo-Controlled Study

Poster Presenter: Giovanni Martinotti, M.D.

SUMMARY:

Introduction: The field of neuromodulation encompasses a wide spectrum of interventional technologies that modify the pathological activity within the nervous system to achieve a therapeutic effect. Therapy, including transcranial direct current stimulation, has shown promising results across a range of neurological and neuropsychiatric disorders. Addictive disorders are a major public health concern, associated with high relapse rates, significant disability and substantial mortality. Unfortunately, current interventions are only modestly effective. Preclinical studies as well as human neuroimaging studies have provided strong evidence that the observable behaviours that characterize the addiction phenotype, such as compulsive drug consumption, impaired self-control, and behavioural inflexibility, reflect underlying dysregulation and malfunction in specific neural circuits. These developments have been accompanied by advances in neuromodulation interventions, both invasive as deep brain stimulation, and non-invasive such as repetitive transcranial magnetic stimulation and transcranial direct current stimulation (TDSC). Among the brain stimulation techniques, TDCS appear to be really promising in the area of addiction psychiatry. In this study we aimed to evaluate the efficacy of a TDCS treatment in Cocaine Use Disorder. Methods: a double-blind, placebo control design was applied to evaluate 30 seeking treatment cocaine addicts, compared with 30 normal controls. Different scales were applied: the Cocaine Craving Questionnaire, the Hamilton depression Rating Scale, the Hamilton Anxiety Rating Scale, the Barrat Impulsiveness scale. Results: after two weeks of treatment TDCS treatment showed to be efficacious in both craving reduction and improvements of psychiatric symptoms. No adverse reaction was described. Conclusion: TDCS treatment appear to be a promising treatment for cocaine addicts. Further studies are required for larger sample and with longer follow-up design.

Psychiatric Inpatients With Comorbid Cannabis and Cocaine Use Disorders: Impact on Impulsivity

Poster Presenter: Gregory Larimer, M.D.

Co-Authors: Shweta Kapoor, Dean Joseph Atkinson, M.D., Crispa Josephine Aeschbach Jachmann, M.D., Teresa Pigott, Melissa K. Allen, D.O.

SUMMARY:

Background: Comorbid Cannabis and Cocaine Use Disorders are particularly prevalent in psychiatric inpatients. Previous studies have linked mood, psychotic, and/or substance use disorders with significantly elevated levels of impulsiveness. The Barratt Impulsiveness Scale (BIS-11) is a commonly administered self-report measure for assessing impulsiveness. Elevated BIS-11 scores have not only been reported to be elevated in Cocaine Use, but BIS-11 scores were predictive of the level of cocaine use in one report. However, there is limited data concerning impulsivity in Cannabis Users. The present study was designed to investigate whether impulsivity is differentially associated with comorbid Cannabis and Cocaine Use Disorder. **Methods:** 184 adult patients with a primary diagnosis of Depressive Disorder, Bipolar Related Disorder, Schizophrenia Spectrum Disorder, or Substance-Related Disorder admitted to the same psychiatric unit at an inner city academic hospital in Houston between 1/13 and 7/14 were assessed using the National Institute on Drug Abuse (NIDA) Modified ASSIST-2 and the BIS-11; Urine Drug Screen (UDS) results were also collected at admission. The BIS-11 measures trait impulsivity in three domains: attention, motor, and

non-planning subscales. Linear hierarchical regression was used to examine the association of the use and risk of use of Cannabis and Cocaine, respectively with the BIS total score and the BIS Subscales (second order). NIDA risk scores for Cannabis and Cocaine, respectively, were used as continuous variables. **Results:** Of the 184 psychiatric inpatients, 55.4% were males with mean age of 35.14 years and was comprised of 50% Non-Hispanic whites, 35.9% Blacks, and @ 10% Hispanics. On the NIDA Modified ASSIST, 60.3% (111) of the inpatients were positive for Cannabis and 39.7% for Cocaine (73). On the UDS, 42% were positive for Cannabis and 19% for Cocaine. Linear hierarchical regression revealed that the β coefficients for Attentional (β=-.293, t=2.135, p<0.034) and Non-planning impulsiveness (β=0.397, t=3.208, p=0.002) scales were significantly correlated with risk of Cannabis Use, whereas only the non-planning BIS-11 Subscale was significantly correlated with risk of Cocaine Use (β=0.435, t=3.427, p=0.001). Additionally, 42% patients were positive for Cannabis and 19% were positive for cocaine on admission per UDS results. **Conclusion:** In this study, Total BIS-11 Score and 2 out of 3 BIS-11 impulsivity trait subscale scores were significantly associated with risk of Cannabis use. The findings suggest that there may be an important link between impulsivity, especially Attentional and Non-planning impulsivity, and Cannabis Use Disorder. In comparison, Non-planning impulsivity was the only subscale significantly associated with risk of Cocaine use, suggesting varying impulsivity profiles in patients with Cannabis Use Disorder in comparison to Cocaine Use Disorder.

No. 4

Self Esteem, Quality of Life and Psychiatric Disturbances in HIV-Positive Drug Dependents Admitted at a Tertiary Care Hospital in Pakistan

Poster Presenter: Imtiaz Ahmad, M.D.

SUMMARY:

Pakistan has 0.1 % prevalence of HIV in adult population but some special segments are associated with threatening prevalence like intravenous drug users (IDU's) where HIV prevails in 21 % of the population. This special segment faces the stigma and discrimination of labels, HIV and Drug dependence. These may contribute to their self esteem, quality of life and mental health deterioration. Current study aims to investigate these variables in HIV positive drug dependents. Objectives: To examine the self esteem, Quality of Life and psychiatric disturbances in HIV positive Drug dependents Design: Cross Sectional Place & Duration: The study was conducted in Model Drug Abuse & Treatment Center DHQ Hospital, Faisalabad, Pakistan from February 2016 to January 2017. Method: 114 HIV drug dependents were recruited for the study through consecutive sampling, Demographic variable Performa, Rosenberg Self Esteem Scale, WHO QOL BREF and Self Report Questionnaire -24 were administered. Results: Most of the HIV drug dependents were between 20-35 years of age, had no or nominal education, were unemployed or laborers and lived in their own houses. About half of the sample lived in urban areas, was married and started abusing drugs on peer pressure. 82.5 % of HIV drug dependents scored lower than the cut off value on Rosenberg self esteem scale and 96% of the total scored more than the cut off set for screening psychiatric disturbances. One sample t-test confirmed both finding that majority of sample had low self esteem and high psychiatric symptomatology demanding psychiatric interview, t(113) = -9.250, p = 0.00 and t(113) = 23.1, p = 0.00 respectively. All 04 domains of QOL moderately and positively correlated with each other. Calculation of the threat they carry for the rest of the society was examined in terms of their practices concerning modes of spread. The data showed that 100 out of 114 used intravenous needles and 63 among these shared these needles with others while 46 reused the syringes. 93 were sexually active and among these 57 have experienced pre marital and extra marital sex, while 35 of them had multiple partners. 46 HIV positive drug users were not fashioned to the protective measures of sex, while 47 of total sexually active have married sexual partners who may transfer the virus to the off springs. Conclusion: HIV positive drug abusers belonged to special population segments like young males, uneducated daily wagers or unemployed. Most of the HIV positive drug abusers had low self esteem and high psychiatric disturbances. Their current practices carry high risk for the spread of the virus. Keywords: Self Esteem, QOL, Psychiatric Disturbances, Risk of HIV spread.

No. 5

Comparison of Residents' Attitudes and Knowledge About Opioid Use Disorder: A Cross-Sectional Study

Poster Presenter: Isabella Morton
Co-Authors: Danae Nicole DiRocco, M.D., Jamie Spitzer, M.D.

SUMMARY:

Background: The United Sates is experiencing an opioid epidemic and confronting it requires advances in medical education and care delivery. Opioid use disorder (OUD) is a disease, but too often, even among medical professionals, it is treated as a character flaw, leading to under-diagnosis and treatment. This study was designed to determine attitudes toward and knowledge about OUD among incoming residents in four training programs, as a baseline for tracking how their attitudes and knowledge change over the duration of training. Methods: A 33-item survey was developed to evaluate incoming residents' knowledge and attitudes toward OUD, including the training they received about OUD in medical school and their state of readiness to manage withdrawal and prescribe treatment. Participants were residents in emergency medicine (EM), internal medicine (IM), obstetrics & gynecology (OB), and psychiatry (Psy). The survey was distributed to interns in their first month of training; participation was voluntary. A five-option Likert scale was used to evaluate attitudes. A score was calculated for each participant based on correct answers to 13 knowledge questions. Results: These are preliminary results from the first year of the 4-year survey. All eligible Psy and OB residents, 88% of the EM residents, and 50% of the IM residents completed the survey; the overall response rate was 75% (52/69). For the aggregated knowledge score, Psy residents had the highest average of 75%, followed by IM, OB, and EM, with scores of 72.8%, 71.4%, and 59.9%, respectively. Across specialties, 38% reported receiving no formal training on OUD in medical school. Only 15.4% reported feeling knowledgeable about OUD treatment and resources in their community. Nearly half of all participants and 71% of EM residents reported feeling unprepared to diagnose OUD. The majority (55.8%) of all residents felt prepared to diagnose opioid withdrawal, and 30.8% felt prepared to treat it. 11.5% of respondents felt prepared to continue outpatient treatment and none strongly agreed that they were prepared to continue outpatient treatment. Only 13.5% of residents agreed that they felt prepared to initiate buprenorphine treatment. An impressive 84% of all residents desired more formal training in residency on the treatment of OUD. Discussion: Formal education on OUD and treatment is lacking for incoming residents across specialties. Our results demonstrate that incoming residents do not have adequate experience or knowledge to address the burgeoning opioid epidemic appropriately and that the vast majority of them want more formal training on OUD during residency. Our results point to the need to develop innovations in education so that physicians in training have access to the knowledge and tools necessary to confront the opioid epidemic.

Comparison of Risk Factors Between Smartphone Addiction Group and Internet Addiction Group

Poster Presenter: Jiwook Kang

SUMMARY:

INTRODUCTION Smartphone addiction and internet addiction is an interesting concern today. The aim of this study is to assess the risk factors associated with smartphone addiction and internet addiction, and compared the significant risk factors between smartphone addiction and internet addiction. METHODS Chungnam National medical college students (N = 92) in South Korea completed the Smartphone Addiction Scale, the Young's Internet Addiction Test, the Body Dysmorphic Disorder Examination-Self Report, Korean Inventory of Interpersonal Problems, Depression Anxiety Stress Scale-21, NEO Five-Factor Inventory, Pittsburgh Sleep Quality Index, Morningness-Eveningness Questionarrie, and Symptom Checklist-90-Revised. RESULTS The risk factors for smartphone addiction were internet use, anxiety, depression, high BDDE-SR, eveningness. In contrast, the risk factors for Internet addiction were male gender, smartphone use, anxiety. These differences may result from unique features of smartphones, such as high availability and various purposes of use that include a tool for interpersonal relationships. CONCLUSIONS Our results will help clinicians in distinguishing

between risk factors for smartphone addicton and Internet addiction. Also these risk factors will be helpful for prevention and treatment of smartphone addiction and internet addiction.

A Clinical Case of Synthetic Cannabinoid (K2)-Induced Second-Degree AV Block

Poster Presenter: Junyong Jia, M.B.B.S.

SUMMARY:

Synthetic Cannabinoid, K2/Spice, has gained great popularity in young population, due to ITS easy accessibility and mild euphoria effects in the past decade. The most common side effects of K2 include euphoria, anxiety, impaired judgement, nausea and vomiting. Psychosis and cardiovascular side effects of tachycardia, ST/T changes, AFib and PVC have also been reported in literature. We reported a case of transient and reversible 2nd degree AV block after the use of K2 in a 30-year old African American female. PubMed searching resulted in no report of such side effect of K2. However, Marijuana was reported to cause 2nd degree AV block in the past. Therefore, this is the first such cardiovascular side effect reported for K2. We also discussed the possible underlying mechanisms of K2 on cardiovascular system and the significant clinical relevance of this newly reported adverse effect of K2.

Measures of Quality of Life Among Opioid-Dependent Individuals in Taiwan: A Comparison Between EQ-5D and WHOQOL-BREF

Poster Presenter: Kai-Tang Chang

SUMMARY:

Background: Brief version of the World Health Organization's Quality of Life (WHOQOL-BREF) and EuroQol-5 Dimension (EQ-5D) are tools widely used for measuring quality of life (QoL). This study aimed to evaluate the measurement properties and the determinants of these two questionnaires in opioid-dependent individuals in Taiwan. Methods: Two hundred participants diagnosed with opioid dependence were recruited from three addiction treatment units in Taiwan. All participants were measured with the EQ-5D, WHOQOL-BREF, opiate treatment index (OTI), and Self-Stigma Scale (SSS). We conducted the comparisons using Pearson correlation and linear regression models. Results: The participants had a mean age of 45.1 years [standard deviation (SD) =7.6 years]. The mean score of health visual analogue scale (VAS) of EQ-5D was 65.17 (SD=15.52) and the utility was 0.89 (SD=1.43). The mean scores of physical health, psychological health, social relationships, and environment domain of WHOQOL-BREF were 13.49 (SD=2.74), 11.84 (SD=2.92), 12.56 (SD=2.74), and 13.33 (SD=2.60), respectively. Pearson correlation coefficient between utility of EQ-5D and four domains of WHOQOL-BREF showed a medium to high correlation (ranged from 0.368 to 0.616), with the highest correlation between physical health of WHOQOL-BREF and utility of EQ-5D. In linear regression model, the psychological adjustment of OTI had the highest influence on EQ-5D (explained variance of 42.6%) and the physical health of WHOQOL-BREF (46.1%). Psychological adjustment also showed an explained variance of 28.4%-38.2% for the other three domains of WHOQOL-BREF. Receiving opioid agonist treatment was a predictor for better EQ-5D and psychological health of WHOQOL-BREF. Stigma (as assessed by SSS) also had a negative impact on both EQ-5D and social QoL. On the other hand, opioid users with a full-time job or a higher monthly income had better scores in EQ-5D and physical, psychological and environment domains of WHOQOL-BREF. Last but not least, sexual life was also a good predictor for both physical and social QoL. Conclusion: The correlations between EQ-5D and WHOQOL-BREF showed the consistency of both instruments in measuring QoL among opioid-dependent individuals. Mental health seemed to have the highest effect on QoL. Furthermore, stigma had a detrimental effect on QoL among opioid users in Taiwan. Receiving treatment, employment, and sexual life were good predictors for a better QoL. Based on the results, an integrated service model may lead to a better outcome. This research was supported by grants from the Ministry of Health and Welfare, Executive Yuen, Taiwan.

No. 9

Alcohol Detoxification Complicated by Previous Withdrawal Seizures and Psychogenic Nonepileptic Seizures

Poster Presenter: Lisa Nicole Oliveri, M.D.
Co-Author: Stephen A. McLeod-Bryant, M.D.

SUMMARY:
Mr. J is a 36-year-old male, with a history of posttraumatic stress disorder, unspecified depressive disorder, opioid use disorder, sedative-hypnotic use disorder, and alcohol use disorder complicated by withdrawal seizures despite being on a benzodiazepine taper. On admission for exacerbation of depression, the patient reported using clonazepam three times daily and consuming 750 mL of liquor daily, with his last use of both substances the previous evening. Mr. J was started on a chlordiazepoxide taper due to his history of withdrawal seizures and recent cessation of heavy alcohol use. Approximately 24 hours after his last use of alcohol, he was found to be in withdrawal with a witnessed seizure. He was transferred to the medical emergency room, where he experienced two further generalized tonic-clonic seizures and was subsequently admitted to Medicine. During admission, he continued to exhibit seizure-like activity, despite the chlordiazepoxide. Neuroimaging and electroencephalogram were completed, and Neurology recommended no further intervention as his presentation was consistent with psychogenic nonepileptic seizures (PNES). He was ultimately medically cleared and tapered off chlordiazepoxide. With the risk of mortality associated with alcohol withdrawal, it is critical to obtain a thorough history to direct patient management. In this poster, we discuss the challenges of determining appropriate detoxification strategies in a patient with prior withdrawal seizures and PNES.

No. 10

Impact of the Opioid Epidemic on the Provision of Substance Use Treatment for Patients Admitted to an Academic Psychiatric Hospital in the Midwest

Poster Presenter: Matthew P. Arrowsmith, M.D.
Co-Authors: Julie A. Niedermier, M.D., Danielle Steelesmith

SUMMARY:
Background: The opioid epidemic is worsening, with overdose deaths tripling between 1999 and 2014.The greatest increase in heroin-related deaths occurred in the Midwest. Comorbidity is common. Among the 9.8 million adults nationwide aged 18 and older with serious mental illness, 23.8% had a co-occurring substance use disorder. 7.2% of adults with any mood or anxiety disorder also met criteria for opioid use disorder, compared to 1.42% of the general population. The authors examined the impact of the epidemic on the likelihood of substance use treatment in the adult population of seriously mental ill patients admitted for psychiatric stabilization at an academic medical center in the Midwest. The goal was to determine if there were trends in the admitted population indicative of comorbid opioid use disorder necessitating initiation or continuation of treatment while hospitalized. Methods: The medication-assisted treatments, buprenorphine, methadone, and naltrexone may be utilized to reduce risk of relapse from opioid use disorders. In the population of adults admitted for psychiatric stabilization, patients may be adjunctively receiving any of these medications or they may be candidates for a trial of buprenorphine or naltrexone, depending on various factors. At this center, methadone cannot be initiated, although maintenance treatment can be provided. The authors reviewed admission data and determined the number and proportion of adult patients prescribed naltrexone, methadone, or buprenorphine while psychiatrically hospitalized for severe mental illness from fiscal year 2015 to fiscal year 2017. It was hypothesized that an increase in the number and percentage of patients receiving buprenorphine, methadone, or naltrexone while admitted for psychiatric stabilization had occurred over the last two years. Results: With regards to buprenorphine, the proportion of patients prescribed buprenorphine while psychiatrically hospitalized in fiscal year 2015 was 1.84 %. In fiscal year 2017, this proportion had increased to 2.80 %, representing an increase of 52.17 % over two years. With regards to naltrexone, the proportion of patients prescribed naltrexone in fiscal year 2015 was 1.07 %. In fiscal year 2017, the percentage of patients prescribed naltrexone increased to 1.80 %, representing an increase of 68.22 % over two years. The proportion of patients receiving methadone treatment over this same time interval was relatively constant, at <0.5%. Conclusions: During the last two years there has been a significant increase in the overall number and percentage of patients receiving

treatment for comorbid substance use disorders with buprenorphine and naltrexone while hospitalized at a Midwestern academic medical center in the heart of the opioid epidemic. This suggests that ongoing vigilance and attention to the assessment and treatment of substance use disorders in severely mentally ill patients presenting in psychiatric crisis is warranted

No. 11

Kratom Craze, Schizophrenic Ways, or Delirium Haze?

Poster Presenter: Matthew Wayne Sharp, D.O.
Co-Author: Kimberlee V. Wilson, D.O.

SUMMARY:

Mr. W. is a 32-year-old Caucasian male with a psychiatric history of benzodiazepine use disorder and major depressive disorder who presented with paranoia, auditory hallucinations, psychomotor agitation, disorganized behavior, incoherent speech and multiple bruises located on the patients, arms, legs, torso, abdomen and face. The patient had recently separated from his girlfriend, who lived in a different country, and would aimlessly look for her from his home. The patient was a limited historian and his history required collateral from family who reported that his symptoms have been worsening over the past 10 years but 7 months prior the patient had a seizure and "was never the same". He was admitted to an inpatient psychiatric hospital. On admission the patient reported taking eight, triple zero sized capsules of kratom a day for the past 6 years. He reported taking this medication for its effects similar to opiates. We considered a differential of kratom-induced psychosis from intoxication/withdrawal vs. delirium vs. sleep deprivation vs. first break Schizophrenia. Being that his symptoms may be less severe if sedated and that kratom is a legal, herbal supplement widely available across the United States of America, this led to concern that the patient may be masking his signs and symptoms of undiagnosed schizophrenia with kratom. A thorough history gathering including a discussion with family about herbal supplements can help elucidate complications of a patient's psychiatric condition. In this poster, we discuss the challenges and importance of identifying patients using kratom as well as other legal synthetic highs and its effect on the presentation of psychotic disorders.

No. 12

""Inexplicable Symptoms of Psychosis": A Case Study on Flakka Iinduced Psychosis "

Poster Presenter: Bhavneet Gujral, M.D.
Co-Authors: Lovejit Kaur, M.D., Michael T. Guppenberger, M.D.

SUMMARY:

Flakka also known as "gravel" is alpha-Pyrrolidinopentiophenone (alpha-PVP) which is a synthetic stimulant of the cathinone class; the latest in a series of synthetic drugs that have become popular in the United States. Included on this list are Ecstasy, Dream, K2 and Bath Salts. People use Flakka for its potential euphoric high but it is also known to easily escalate into frightening delusions, paranoia, psychosis, extreme agitation, and altered mental status. We are describing the case of a 45 year old male who reported taking Flakka at a concert and developed symptoms of paranoia, aggression and poor sleep requiring a prolonged hospital course of 43 days including admissions to medicine and psychiatry. On initial presentation, the patient was intoxicated and a poor historian. His family reported daily alcohol use, and his urine toxicology was positive for marijuana and benzodiazepines. Flakka was not identified on the urine toxicology and etiology of his behavior was unclear for the longest period of his hospital course. He was started on Risperdal 0.5 mg every morning, 1.5 mg every night, with Ativan and Clonidine as needed. He was placed on CIWA protocol but continued to manifest ongoing symptoms of withdrawal for several days, therefore a barbiturate tolerance test was completed (up to 700 mg without nystagmus or significant sedation) and the patient was placed on a phenobarbital taper. By the 10th day of psychiatric admission, the patient's hospital course was further complicated which required intensive care unit admission (ICU) for ongoing delirium possibly due to withdrawal, elevated BUN/Cr and hypernatremia. He later developed hyperchloremia, hematuria, rhabdomyolysis, transaminitis, worsening hypoxia and aspiration pneumonia which required oxygen support and intubation along with intravenous antibiotics. He continued to be aggressive in the ICU

which required restraints, propofol and precedex drip, in addition to Haldol and Ativan. The patient started to show gradual improvement in his symptoms after one month and at that time was started on Geodon 20 mg twice a day with meals and Klonopin 5 mg every 4 hours for agitation. The patient demonstrated improvement on this regimen and was successfully discharged on the 43rd day of admission. Flakka acts as a norepinephrine-dopamine reuptake inhibitor with IC50 values of 14.2 and 12.8 nM, respectively, similar to its methylenedioxy derivative MDPV found in bath salts which potentially leads to psychosis. The presence of inexplicable psychotic symptoms which have a prolonged course should be investigated for possible differentials such as substance use. Physicians should be aware of the difficulty detecting synthetic cannabinoids using regular urine drug screens, and their association with psychosis.

No. 13

The Effectiveness of Gabapentin in Reducing Cravings and Withdrawal in Alcohol Dependence: A Meta-Analysis

Poster Presenter: Saeed Ahmed, M.D.

SUMMARY:

Background: Although research has examined the efficacy of gabapentin in the treatment of alcohol withdrawal and cravings, the findings were not conclusive. To this end, the current meta-analysis synthesized previous findings and examined the overall effect of gabapentin on alcohol withdrawal and craving. Methods: Ten studies met the inclusion criteria for the current study. We conducted three sets of meta-analyses depending on the research design and specific data reported in a given study. These meta-analyses were examination of outcomes from (a) single group pretest-posttest changes, (b) posttest differences between independent groups, and (c) differences in pretest-posttest change scores between independent groups. Standardized mean difference (SMD) scores for each study were computed and subsequently meta-analyzed in the relevant design-specific meta-analysis, using random effects models. Results: Statistically significant effect sizes were found for craving and withdrawal in the meta-analysis of single-group pretest-posttest outcome changes. However, these effects were associated with a high level of heterogeneity. By contrast, the meta-analyses of posttest differences between independent groups as well as the meta-analysis of differences in pretest-posttest change scores between independent groups did not yield significant effect sizes. Conclusion: Our results suggest that Gabapentin treatment for alcohol craving and withdrawal appeared to be at least moderately effective. However, given the limited number of well-designed studies, these findings require further research, using primary studies that use more rigorous methodology. Discussion: The effective use of the FDA-approved agents in the management of alcohol use disorder include medical and psychiatric comorbidities, poor medication adherence, and problems with tolerability. As the body of research on alternatives to these agents continues to grow, we sought to improve the understanding of gabapentin's strategic role in the management of alcohol dependence and withdrawal. Gabapentin is not hepatically metabolized, making it potentially preferable to current FDA-approved agents, especially in this target population with a high prevalence of hepatic insufficiency. Unlike acamprosate, gabapentin can also be used for patients with the renal function below 20 mg/dL. Because of its safety profile with fewer side effects, lack of interactions with other medications added property of sleep improvement for individuals with alcohol use disorders, and the fact that it is generally well-tolerated makes gabapentin a promising agent in AUD treatment.

No. 14

Adding Psychotherapy to the Naltrexone Treatment of Alcohol Use Disorders: A Meta-Analysis

Poster Presenter: Saeed Ahmed, M.D.

SUMMARY:

Background: The added impact of psychotherapy with naltrexone treatment in alcohol use disorders (AUD) has not been adequately studied. In addition to examining the effect of naltrexone on various clinical outcomes in AUD, the current meta-analysis examined the hypothesis that psychotherapy is a significant moderator that influences AUD-related outcomes and that naltrexone combined with psychotherapy is associated with significantly better AUD-related outcomes than naltrexone alone.

Methods: A total of 28 studies (Nnaltrexone=1610; Nplacebo=1613) were included. For each of the studied outcomes, random effects model meta-analyses of all studies were carried out separately for all studies, as well as a subgroup analysis of studies with and without psychotherapy. Subsequently, the random effects model pooled estimates from studies with and without psychotherapy were compared using a Wald test. A mixed-effect model, incorporating psychotherapy as a moderator, was used to examine the impact of psychotherapy on treatment outcomes. Results: The random effects model meta-analyses revealed that naltrexone had a significant treatment effect on abstinence (OR = .30 CI=[.06, .56]) relapse (OR = -.43 CI=[-.59, -.28]) and Gamma-Glutamyl Transferase levels (SMD = -.16 CI=[-.29, -.04]), but not cravings (SMD = -.11 CI=[-.31, .10]) . The pooled estimates for studies with and without psychotherapy were not significantly different for any of the studied outcomes. Psychotherapy was not a significant moderator in the mixed effects models for any of the studied outcomes. Conclusions: Naltrexone treatment is efficacious in reducing alcohol consumption, but not reducing cravings. Adding psychotherapy on top of naltrexone did not result in any significant additional benefit for AUD patients. Discussion: The current study examined the hypotheses that naltrexone is efficacious in treating AUDs and that psychotherapy combined with naltrexone significantly augments AUD-related treatment outcomes. In relation to the former, our results have generally indicated that naltrexone had been efficacious in treating AUDs. Specifically, the pool estimates indicated significant treatment effects in improving self-reported alcohol consumption outcomes such as abstinence, relapse, and objectively measured GGT, which is a widely used and a highly specific biomarker for excessive alcohol consumption. However, there was not a significant treatment effect on cravings. It is worthwhile to note that the current study is the first to document the meta-analytic findings of naltrexone on GGT and alcohol-related cravings. In relation to the second hypothesis, adding psychotherapy to the naltrexone treatment of AUDs did not significantly augment treatment outcomes; the combined treatment of psychotherapy and naltrexone was not any better than naltrexone alone.

No. 15

Chronic Alcoholism, Traumatic Brain Injuries, and the Development of Korsakoff's Psychosis: A Case Report

Poster Presenter: Shirish Patel, M.D.
Lead Author: Ivanshu Navinprakash Jain, M.D.
Co-Authors: Ambreen Rahman, M.D., Charles Huston Dukes, M.D., Britta Ostermeyer, M.D.

SUMMARY:
Mrs. F., a 58-year-old Caucasian female with a past psychiatric history of alcohol use disorder and traumatic brain injury, presents to the emergency department for higher level of care for altered mental status, agitation, and significantly elevated levels of ammonia following a two week stay at a residential substance abuse treatment facility for visual hallucinations and paranoia with a resultant diagnosis of schizophrenia. The patient was not cooperative while being interviewed and reported seeing holograms of people that were coming after her. Throughout the interview, her eyes were closed, spoke slowly, appeared drowsy, and could not provide much history. The patient's boyfriend stated that she routinely drank a six-pack of beer twice a week. She was admitted to the inpatient medicine service for alcohol withdrawal. The medical team considered the differential diagnosis of alcohol withdrawal delirium, neuroleptic malignant syndrome, and acute Parkinsonism. The patient's overall condition improved after starting a Clinical Institute Withdrawal Assessment for Alcohol (CIWA) protocol and chlordiazepoxide; however, she continued to have delusional and paranoid thoughts. Neuropsychiatric testing revealed significant impairments in the patient's working memory, cognition, and performance of activities of daily living. Further testing revealed visuospatial agnosia out of proportion typically associated with a right parietal dysfunction. Imaging studies found severe cerebral volume loss - disproportionate to age, atrophic mammillary bodies, and mineralization within the basal ganglia; classic for all of the typical findings in either chronic alcohol or toluene abuse, suggestive of Korsakoff's syndrome. Together with her persistent delusions and paranoid behavior a

diagnosis of Korsakoff's psychosis was established. The patient's longstanding history of alcohol abuse, traumatic brain injury and poor activities of daily living functioning gave rise to concern about the suboptimal management of her residual symptoms of her traumatic brain injury and poor diet that could have worsened the effects of alcoholism on her mood and cognition; possibly overlooking differential diagnoses such as Pellagra Encephalopathy and early onset Parkinson's disease complicated by chronic alcoholism. In this poster, we discuss the challenges of differentiating alcohol-related psychotic symptom etiology during the treatment of alcohol withdrawal in patients with previous traumatic brain injuries.

Case Report of Takotsubo Cardiomyopathy in a Psychiatric Patient With Longstanding Rheumatoid Arthritis

Poster Presenter: Ivanshu Navinprakash Jain, M.D.
Co-Authors: Shirish Patel, M.D., Ambreen Rahman, M.D., Charles Huston Dukes, M.D., Britta Ostermeyer, M.D.

SUMMARY:
A 64-year-old Caucasian female with a past psychiatric history of bipolar disorder, depression, hypothyroidism, rheumatoid arthritis and cardiac arrhythmias was taken to a local hospital after her daughter found her at home in a disheveled, delirious and anxious state and had not slept in two days. There she was given IV fluid resuscitation for hypotension and hypokalemia. She was admitted to the inpatient medicine service. Her daughter reported that her mother had been living alone for quite some time without any difficulty; however, her mood and ability to perform her activities of daily living had diminished over the past year, shortly after the passing of her husband. The daughter states that she suspects that her mother had been taking increasing amounts of analgesics after recent surgery for closed angle glaucoma. Few weeks prior to her presentation, the daughter reported that her mother became completely withdrawn, stopped eating, drinking, and could not function. Medication history revealed that she was tried on multiple antidepressants and antipsychotics for her symptoms of depression and bipolar disorder. She had also been taking daily levothyroxine for hypothyroidism and receiving once-weekly injections of a tumor necrosis factor (TNF) alpha inhibitor for the treatment of rheumatoid arthritis. Electrocardiography (ECG) test results showed ST elevation with multiple premature ventricular contractions (PVCs). Transthoracic Echocardiography (TTE) results showed findings consistent with markedly reduced left ventricular systolic function with extensive akinesis of the mid- to apical cavity with relatively preserved basal contractility. The ECG and TTE findings together with the patient's recent history of severe emotional stress were consistent with Takotsubo Cardiomyopathy (TCM): a reversible neurogenic stress-induced cardiomyopathy also known as "Broken-heart Syndrome." This led to the concern of the patient's ongoing medical treatments for rheumatoid arthritis and hypothyroidism affecting her mood and ability to function independently while being severely emotionally distressed over the loss of her husband. In this poster, we discuss the causal links between the long-term treatment of mood disorders and multiple comorbid medical conditions and how they could predispose a patient towards presenting with psychosomatic symptoms.

Medication Noncompliance and Adverse Drug Events: A Case Report on Neuroleptic Malignant Syndrome

Poster Presenter: Ambreen Rahman, M.D.
Co-Authors: Shirish Patel, M.D., Ivanshu Navinprakash Jain, M.D., Charles Huston Dukes, M.D., Britta Ostermeyer, M.D.

SUMMARY:
Ms. N., a 57-year-old Caucasian female with a past psychiatric history of Bipolar disorder, Parkinsonism and substance use disorder, presents to the Emergency Department after she was found at her home by her daughter in a confused and lethargic state. Her family reported similar incidents almost every other month and were thought to be related to poor medication compliance, stating that she does not take her medications as prescribed, often forgetting that she took some of her medications, and at times taking more. The patient's family further states that she never runs out of them,

possibly taking them all at once rather than throughout the day. During evaluation she was lethargic, somnolent and non-response; her family reported that she had not gotten out of her bed 'immobile and motionless' for 2-3 days before her presentation. She was admitted to the intensive care unit (ICU) for the management of rhabdomyolysis, respiratory distress, and acute renal injury. The medical team considered the differential diagnosis of Neuroleptic Malignant Syndrome (NMS), Serotonin Syndrome, Malignant Catatonia and medication toxicity. She was started on a regimen of lorazepam, haloperidol and dexmedetomidine for agitation while in the ICU, where her symptoms soon improved. This led to the concern of possible withdrawal of L-Dopa and concurrent inadvertent mood stabilizer overdose given the patient's history of poor medication compliance and purposely taking more than the recommended doses at times. NMS is a life-threatening complication, patients with psychiatric histories presenting with a cluster of autonomic dysfunction, motor and behavioral symptoms and abnormal laboratory results need to be treated with careful consideration of their medication regimen and compliance. A full medical and neuropsychiatric workup and history gathering can help reveal sources of difficulties in a patient's ability to be compliant with a medication regimen. Finding formulations and alternate routes of administration can help improve medication adherence. In this poster, we discuss the challenges of managing adverse drug events in a patient with a history of medication noncompliance, mental illness, and substance abuse disorder.

No. 18

Serotonin Syndrome, Sjogren's Syndrome, and the Impact of Pharmacogenomics: A Case Report

Poster Presenter: Shirish Patel, M.D.
Lead Author: Ambreen Rahman, M.D.
Co-Authors: Ivanshu Navinprakash Jain, M.D., Charles Huston Dukes, M.D.

SUMMARY:

A 55-year-old Caucasian female with a history of depression, anxiety, PTSD, migraines, Sjögren's syndrome, and Fibromyalgia presents to the psychiatric consult service with recent onset of anxiety and restlessness. The patient described this as a "fish-flopping sensation," which occurred on the second day of admission for an ongoing headache due to hydrocephalus versus normal pressure hydrocephalus in the neurosurgery department. She reported similar symptoms approximately ten years ago when she started taking Buspirone 5mg PO TID, which was then discontinued. Further chart review revealed that she had an extensive list of medication allergies or past reactions from medications including Allopurinol, Rosiglitazone, Exenatide, and most notably triptans, selective serotonin reuptake inhibitors (SSRIs), serotonin-norepinephrine reuptake inhibitors (SNRIs) and atypical antipsychotic medications. On examination, she showed muscle rigidity, hyperreflexia, spontaneous myoclonus, sweating, tremulous and flushed. Her blood pressure was 211/97mm Hg, a pulse rate of 95 beats per minute, a respiratory rate of 20 per minute, and a body temperature of 36.3°C. Her Holter monitoring occasionally showed sinus tachycardia. Diagnosis of Serotonin Syndrome was made, and venlafaxine and meperidine were held, and Diazepam was continued with fluid replacement. The patient's symptoms improved the next day, and she was discharged with recommendations for outpatient follow up with her Psychiatrist. Serotonergic agents are widely used as first-line choices in the treatment of patients with major depressive disorder (MDD). Drug metabolism is taken into account through consideration of genetic variations of the cytochrome P450 (CYP) enzymes and functional polymorphisms of the 5-HT2A gene can lead to alterations in 5-HT concentrations. A patient who is a poor metabolizer would require a lower antidepressant dose to avoid possible adverse drug effects, and may also be more likely to fail multiple antidepressant trials due to early or have severe adverse reactions. The patient's clinical presentation of headaches and hydrocephalus demonstrate a correlation with her extensive history of Sjogren's Syndrome and subacute symptoms of serotonin toxicity presenting as allergies and side effects to serotonergic agents before developing an acute episode of serotonin syndrome. For depressed patients with persistent symptoms, a thorough physical examination and medication review are important to detect signs of serotonin toxicity. In this poster, we discuss the importance of antidepressant medication monitoring

and pharmacogenomic testing during the treatment of mood disorders could help to diagnose serotonin toxicity in patients taking multiple medications.

No. 19

Exercise, Depression, and E-Health Monitoring

Poster Presenter: Shirish Patel, M.D.
Co-Authors: Andrew Hanna, Preyas Patel, Sally Abudiab, Ryan Jugdeo, Martin A. Katzman, M.D.

SUMMARY:
The benefits of incorporating physical activity to treat various chronic diseases such as obesity, dyslipidemia, and hypertension have been well documented; however, adherence to lifestyle and behavioral interventions continues to be problematic in clinical practice, especially for patients afflicted with depression. Various studies have shown that exercise has a substantial antidepressant effect on patients with depression. However, symptoms of depression such as fatigue and apathy can often hinder a patient from engaging in exercise. As such, addressing this lack of adherence and creating strategies for clinicians to use may help increase adherence rates following an exercise prescription. The use of activity trackers to monitor and quantify a patient's physical activity levels has been proposed as a method to address the lack of adherence in patients looking to undergo behavioral modification. Due to the popularity of wearable activity trackers such as the Fitbit, Jawbone, and Misfit, an opportunity may exist to integrate promising technology into lifestyle modification interventions for patients with depression. The impact of increasing physical activity in this population may combat many of the core symptoms of depression (mood, cognition, and fatigue), as well as reducing secondary symptoms associated with various chronic diseases. This scoping review will examine existing literature regarding the use of activity trackers as a method to increase exercise adherence rates following an exercise prescription for patients afflicted with depression.

No. 20

Assessing Depression Severity With a Self-Rated Versus Rater-Administered Instrument in Patients With Epilepsy

Poster Presenter: Christine Marie Collins, M.D.
Co-Authors: Erin Campbell Fulchiero, M.D., Martha Sajatovic, M.D., Shirin Jamal-Omidi

SUMMARY:
Rationale: Nearly 25% of patients with epilepsy have comorbid depressive disorders, which impact quality of life and frequently require concurrent treatment. In order to identify and manage depressive symptoms appropriately, clinicians need screening tools and other standardized instruments that can accurately identify those with clinically significant depression. This secondary analysis from 2 epilepsy self-management studies compared depression severity ratings and case identification using a "gold standard" self-rated depression screening tool and a "gold standard" rater-administered depression severity instrument. Methods: Data for this analysis were derived from pooled baseline and longitudinal data from 2 epilepsy self-management randomized controlled trials that tested a similar experimental intervention. Both studies assessed depression with the self-reported 9-item Patient Health Questionnaire (PHQ-9) and the rater-administered Montgomery Asberg Depression Rating Scale (MADRS). The PHQ-9 is widely used self-rated depression screening measure used in primary care settings and for population health surveillance, although it has been understudied as applied to people with epilepsy. The MADRS is a rater administered instrument widely used as a primary outcome measure in depression clinical trials. For this analysis, total depression severity scores and case identification using established thresholds for no/minimal, mild, moderate/moderately severe, and severe depression were assessed using both the PHQ-9 and MADRS. Results: The sample consisted of 164 adults with epilepsy, mean age 43.1 years (SD 12.2), with demographic and clinical variables between the 2 studies being generally similar. There were N= 107 women (64.8 %), N= 106 African-Americans (64.2%), and N=51 (30.9%) whites. Study participants had epilepsy for an average of 22.1(SD 15.5) years. Mean past 30-day seizure frequency at baseline was 3.1, SD 11.6. Baseline mean PHQ-9 was 10.8, SD 6.8 with 32 (19.6%) classified as minimally depressed, 47 (28.8%) classified as mildly depressed, 37 (22.7%) as moderately depressed, 27 (16.6%) as moderately severely depressed and 20 (12.3%) as

severely depressed. Baseline mean MADRS was 18.5, SD 11.3 with 30 (18.8%) classified as not depressed, 27 (16.9%) classified as mildly depressed, 92 (56.1 %) as moderately depressed, and 11 (6.9%) as severely depressed. The Pearson correlation between total PHQ-9 and total MADRS was =.843 ($p<0.01$), although case classification by depression severity varied somewhat between the two instruments. Conclusions: Standardized measures to screen and evaluate depression severity can help to identify cases and monitor treatment progress. The PHQ-9 and MADRS both perform well in assessing depression in patients with epilepsy, although administration burden is less with the PHQ-9 thus making it likely preferable for settings where time and epilepsy specialty resources are limited.

No. 21

Cerebellar Cognitive Affective Syndrome in Two Veterans: Case Studies and a Review of the Literature

Poster Presenter: Clare Gallego Bajamundi, D.O.

SUMMARY:

In 1998 Dr. J.D. Schmahmann published a paper in Brain in which he introduced the concept of "cerebellar cognitive affective syndrome (CCAS), also known as Schmahmann's syndrome. Cerebellar posterior lobe and vermal damage seem important in the development of this syndrome (1). Symptoms include executive deficits, disruption of visuospatial cognition, personality changes, and linguistic impairments. More recent research has expanded on this idea by evaluating how lesions in specific areas of the posterior cerebellum and vermis disrupt connections between the cerebellum, limbic and paralimbic system (2,4). A recent paper in Neuroimaging used voxel based lesion mapping and determined that CCAS was associated with lesions in lobules VII and VIII in the posterior cerebellum (3). This region has heavy connections with the medial rostral pons which connect to various association cortices of the cerebrum (5). This case study reviews the neuropathology and symptomatology of CCAS in the context of one patient with a large posterior cerebellar lesion and another with mega cisterna magna. It also adds to the limited literature on management strategies for this syndrome. Two veterans seen at our VAMC presented with various symptoms of PTSD, MDD, Bipolar Disorder and GAD but yet did not meet the full diagnostic criteria for any of these disorders. The first patient was initially being seen for PTSD as he was an army veteran in the Vietnam War. Starting in 1992 the patient began to feel more depressed, extremely anxious and was now experiencing auditory hallucinations. He received a new diagnosis of MDD with psychosis. However, over the years the patient developed mood lability, impulsivity and his cognition also continued to worsen. A 2008 CT of the head showed a cavernous malformation within the right posterior cerebellar hemisphere. An MRI in 2016 showed the lesion now had characteristics of a cavernoma. The second veteran had a diagnosis of schizophrenia from when he was in the Air Force in 1968. In 2001 the patient noticed a change in his symptoms. He was now endorsing 3-4 manic episodes a month and between these periods felt very depressed and anxious. In 2003 he began to have problems with anger control, worsening cognitive deficits and mild ataxia. A CT of the head was done in 2011 and mega cisterna magna was noted. Both patients have received continuous psychiatric management and therapy through the VA so we are able to provide a detailed course of treatment prior to and after recognition of this syndrome. Patients with cerebellar pathology can present with a collection of symptoms that do not discreetly fit one psychiatric diagnosis. These symptoms may even appear as just a worsening of preexisting symptoms. This can make diagnosis and treatment difficult. Through this review and case study we will highlight the most recent research in the neurobiology of this syndrome and provide insight into the long term management of these patients.

Ketamine Infusion as Bridging Agent to Adjunctive Lithium Therapy in Treatment Resistant Depression: Case Report and Literature Review

Poster Presenter: Dimal D. Shah, M.D.
Co-Author: Raluca Stefanescu-Sturz, M.D.

SUMMARY:

Treatment resistant depression is considered after two trials of antidepressants from different pharmacological classes failed to produce a significant clinical improvement. For some patients,

SSRIs and bupropion as adjunctive therapy may not significantly improve depression. Ketamine, an NMDA receptor antagonist, may be used in treatment resistant depression. A 58 year old Caucasian male with PPHx of MDD and unspecified anxiety disorder was admitted to an acute psychiatric unit on a voluntary commitment for worsening depressed mood and increased anxiety over the past several weeks. For the past two weeks, he also had suicidal ideations with a plan to overdose on prescribed clonazepam. He detailed poor sleep quality and patterns, decreased appetite with significant weight loss, difficulty concentrating, and decreased energy levels. He experienced two episodes of palpitations, diaphoresis, shortness of breath and tremulous upper extremities within four days prior to admission. He was diagnosed with Major Depressive Disorder in his twenties and had adequate trials of sertraline and fluoxetine with marginal clinical improvement. Patient tried amitriptyline, aripiprazole, and brexpiprazole as adjunctive therapies with minimal improvement in symptoms. Brexpiprazole was stopped within days of initiation due to intolerable side effects. He is adherent to his current regimen of duloxetine 120 mg daily, bupropion ER 300 mg daily, buspirone 20 mg q12h, and clonazepam 1 mg q12h. Duloxetine dose was increased from 90 mg to 120 mg approximately two weeks prior to admission by his outpatient psychiatrist. Patient attends a structured outpatient program for several years. During this admission, he was diagnosed with treatment resistant depression and considered for ECT; however, patient had fixed, negative preconceived notions about such therapy. Patient's home medications were continued as inpatient, but buspirone frequency was increased to TID to manage his anxiety. Patient was also started on lithium for adjunctive therapy. While titrating lithium to a therapeutic dose, patient received two doses of ketamine infusion 48 hours apart at 0.5 mg/kg in 100 cc normal saline administered over one hour. Patient's suicidal ideations subsided within 24 hours of the first dose of ketamine; his depressed mood improved with each dose. At time of discharge, patient denied suicidal ideations and had dramatically improved mood and affect. His anxiety was better managed, as well. He was discharged on the same home medications with an increased frequency of buspirone and addition of lithium. His lithium level was within therapeutic range. Ketamine infusion should be considered as a bridging agent to decrease suicidal ideations and improve depressed mood in patients with treatment resistant depression as lithium is initiated and titrated to therapeutic levels.

No. 23

A Tale of Two Syndromes: A Case Report of Concurrent Catatonia and Delirium

Poster Presenter: Diana M. Robinson, M.D.
Co-Author: Donna T. Chen, M.D.

SUMMARY:
Delirium and catatonia share signs and symptoms yet rarely are diagnosed at the same time. Indeed, the DSM-V gives priority to delirium as a preemptive diagnosis. Both catatonia and delirium result in significant morbidity and mortality. However, given the divergent treatment recommendations for delirium and catatonia, consideration of their possible co-occurrence is critical to providing good patient care. We describe a patient with long-standing schizophrenia and multiple medical problems who developed delirium and catatonia and review the literature to provide guidance on 1) determining when a patient is suffering from catatonia, delirium, or both; 2) differentiating catatonia from neuroleptic malignant syndrome and other life-threatening conditions; and 3) considering treatment options in the face of these three diagnoses. Case Description: EP is a 76 year old man with a long history of schizophrenia and multiple medical problems, including heart failure who presented to the emergency department via EMS for evaluation of dyspnea. He was admitted to the cardiac intensive care unit for cardiogenic shock. Psychiatry was consulted for confusion. The initial evaluation was significant for schizophrenia stable on haloperidol with acute changes in depressed mood, perseveration, and a MMSE of 26. He was diagnosed with hypoactive delirium that was expected to improve with treatment of his acute medical problems. His longstanding psychotropic regimen of haloperidol 5mg QHS, mirtazapine 15mg QHS, and trazodone 100mg QHS was continued. The patient began to have episodes of mutism and negativism. By day 6, catatonia was suspected due to

a MMSE of 6 and a Busch Francis catatonia rating scale (BFCRS) score of 15 for predominant stereotypy, perseveration, and withdrawal. An EEG ruled out non-convulsive status epilepticus and was consistent with encephalopathy/delirium. The patient improved significantly after IV lorazepam challenge to a BFCRS 6. Based on the complicated nature of his medical and psychiatric comorbidities, electroconvulsive therapy was discussed, but the patient's medical condition was too tenuous. Over the next month the patient alternated between appearing more catatonic or delirious and required balancing doses of lorazepam and haloperidol to treat the catatonia, delirium, and schizophrenia. He was finally stabilized on lorazepam 1mg po TID and haloperidol 6mg QHS with a BFCRS of 0 and baseline mental status. He was discharged a month later to a skilled nursing facility for significant deconditioning. Discussion: This medically complicated patient's co-occurring catatonia and delirium in the context of well-controlled schizophrenia highlights many clinically important diagnostic and treatment dilemmas that will be addressed further in the discussion. The evidence for different treatments will be discussed including benzodiazepines, electroconvulsive therapy, amantadine, memantine, and topiramate.

No. 24

Neuropsychiatric Debut as a Presentation of Guillain-Barré Syndrome: An Atypical Clinical Case and Literature Review

Poster Presenter: Dinesh Sangroula, M.D.

SUMMARY:

Background: The classical clinical presentation of Guillain-Barré Syndrome (GBS) is that of progressive muscular weakness of the lower limbs extending proximally with hyporeflexia or areflexia after two to four weeks of an acute mild-moderate infections. Neuropsychological signs such as behavioral and mental status changes have been described in the literature as components of post-GBS syndrome. Nevertheless, none case has been identified so far which reported behavioral and central nervous system (CNS) symptoms of GBS before the onset of the motor symptoms. We are reporting a unique case of GBS which presented very atypically with psychiatric and behavioral symptoms prior to motor symtpoms and treated successfully with plasmapheresis and short term selective serotonin reuptake inhibitor (SSRI). Case Presentation: A 24-year-old, single, Guyanese male without any significant past medical and psychiatric history presented with a chief complaint of sudden onset, episodic, progressive, frontal-parietal headache, 8/10 in severity for 24 hours. Family members reported that one week prior, patient was acting differently at home; talking less than usual, looking sad, isolating himself, being easily frustrated and irritable, decreased energy or fatigue, and behavioral changes with violent outburst. All physical examination including neurological exam was normal at presentation including the laboratory results (except white blood cells count 17,000) and imaging including MRI. On psychiatric evaluation, patient was observed to be depressed and anxious with decreased psychomotor activity, slowed speech, lack of facial expression with markedly flat affect, and disconnect from his surroundings. Definitive diagnosis could not be made due non-specific depressive and anxiety symptoms. The patient was started on escitalopram 10 mg after the first week of hospitalization. After two weeks, the patient suffered a fall while trying to get to the bedside commode when he was found to have proximal lower extremity weakness and the first decrease in DTR's of bilateral knee. Neurology recommended lumbar puncture which showed markedly elevated CSF protein concentration (851 mg/dL) with cyto-albuminologic dissociation and minimal lymphocytes in the CSF, findings which are essentially pathognomonic for GBS. The patient was successfully treated with five sessions of plasmapheresis in an alternating day fashion while continuing SSRI treatment. Conclusion: While GBS is traditionally thought of as a peripheral neuropathy, growing evidence exists to support a central component of the disease. This must be taken into consideration so as not to miss diagnosis and therefore treatment of this potentially life-threatening disease. CNS involvement is an aspect of GBS in which further research is needed. Contrast enhanced MRI at disease nadir may help to identify CNS involvement in GBS and would be worthy of study in the future.

No. 25

Identifying Trends in Incidence of Delirium During Inpatient Hospitalizations to Determine Development of Prevention Strategy

Poster Presenter: Elaine Leo, D.O., M.H.A.
Co-Authors: Suporn Sukpraprut-Braaten, Andrew J. Powell, M.D., Todd Brackins

SUMMARY:
Delirium has symptoms of inattentiveness and disorganized thoughts or change in consciousness level. Symptoms develop acutely and fluctuate throughout the day. In this study,"delirium" is a conglomeration of ICD9&10 codes describing altered mental status or metabolic encephalopathy. Patients vulnerable to delirium have predisposing risk factors of older age, male, history of dementia or delirium, hearing or vision impairment, or chronic renal or hepatic disease. Some events precipitating delirium are infections, sleep disturbance, dehydration, immobilization, alcohol or drug withdrawal, hypoglycemia, and extreme pain. Interest occurred after treating a delirious patient on medical floor who was paranoid and aggressive. Research goal was to analyze trends in hospital acquired delirium to determine area of focus for starting prevention strategy. Methods: Retrospective cross-sectional analysis of discharge data from patient admissions at County hospital's medical or observational unit for at least 24 hours between Jan 1, 2011 and October 13, 2016. Data set queried: 36,165 total patient encounters. Encounters with discharge diagnosis of delirium =2,266; then excluded subset of encounters that had mental status change as problem on admission (2042 encounters). The remaining 224 encounters were determined to have hospital acquired delirium and analyzed for trends. Primary end point was incidence of delirium. Null hypothesis= incidence of hospital-acquired delirium develops randomly. Alternative hypothesis= incidence of hospital-acquired delirium is greater with predisposing risk factors or precipitating factors. Factors selected for analysis: age, sex, distance from patient's home city, discharge unit, directionality of windows in patient rooms and season as a way to extrapolate amount of sunlight affecting circadian rhythm and sleep. Results: Delirium Incidence Rate: 0.62%. Prevalence rate: 6.26%. Female encounters: 53%. Greatest occurrence of hospital acquired delirium 29% of time in 71-80 years old. 107 encounters occurred in patients living <15 mi. from hospital. 4 encounters occurred in patients living > 75 miles from hospital. Encounters with CCU involvement or discharged from surgery floor had more hospital acquired delirium. CCU sun atrium rooms had the most hospital acquired delirium encounters per room. Comparing patient rooms by direction the room's windows faced had statistically significant results. Incidence of delirium in different seasons was not statistically significant.Conclusion: Both men and women develop delirium. Distance of hospital from home is not protective. There were great limitations on data available. Patient location when delirium occurred was not captured. There are many confounding factors. Opening and closing of window blinds may affect sunlight and was not controlled. Measurement of sleep quality was not available. Interventions to prevent delirium need to address multiple components.

No. 26

Extensive Right Frontal Gray Matter Heterotopia Presenting as Social Anxiety and Minor Developmental Delays in an 11-Year-Old Boy

Poster Presenter: Elio Pedroso Conroy, M.D.
Co-Authors: Abhishek Wadhawan, M.D., Nasima Nusrat, Farooq Mohyuddin, M.D.

SUMMARY:
Gray matter heterotopia (GMH) are a group of disorders characterized by abnormality in the development of cerebral cortex, resulting from abnormal migration of neuroblasts. As a consequence, ectopic gray matter may be found in various locations within the brain, ranging from periventricular area, white matter, or the subpial area. This in turn, may lead to neuro-psychiatric symptoms, the severity of which depends on the location and size of the lesions, and the associated malformations in the brain. Epilepsy, neuro-developmental abnormalities, autism spectrum disorder, mood symptoms, psychosis, anxiety, and behavioral disturbances have been frequently reported in patients with GMH. We highlight a case of an 11 year old boy with right frontal lobe heterotopia, who initially presented with social anxiety and minor developmental delays. AJ is a 11 year-old Caucasian male, born with elective artificial

insemination to a female couple, who presented with complaints of severe anticipatory anxiety in the context of new social settings and nocturnal enuresis. His symptoms of social anxiety were first noticed at the age of 9 years. His developmental history was significant for lack of crawling, lack of coordination (gross-motor control), and borderline difficulty with mathematics at school. His mental status was significant for a guarded attitude, poor eye contact, anxious mood, tearful affect, delayed latency in articulating sentences, and thoughts related to fear of unknown situations or losing control. He received Fluoxetine 10mg PO daily and psychotherapy for two years along with physical therapy, which helped him moderately in managing his anxiety and regaining his daily functioning. Over the course of treatment, he was diagnosed with social anxiety disorder. When AJ was 11 years old, he had his first episode of complex partial seizure, which prompted a neurological consult. Brain MRI imaging studies revealed extensive right frontal transmantle GMH, with associated multifocal right frontal lobe polymicrogyria, hypoplasia of the entire right frontal lobe, including the basal ganglia, and hypoplastic corpus callosum with absent rostrum, genu, and splenium. EEG revealed subclinical seizure activity involving the right frontopolar region during sleep. Neuropsychological evaluation revealed deficits in executive functioning, processing speed, and graphomotor control. AJ was started on Oxcarbamazepine 450mg PO twice a day, and no new episodes of seizures were reported after that. In AJ, GMH probably led to all of his neuro-psychiatric symptoms. GMH follows an X-linked, or an autosomal pattern of inheritance. For GMH patients with intractable epilepsy, surgical resection of lesions can be done. There is dearth of literature on managing the psychiatric symptoms associated with this disorder. This case underscores the need for psychiatrists to be aware of this rare cause of neuro-psychiatric symptomatology in patients of all age groups, especially children.

No. 27

A Reverse Phineas Gage? Unique Neuropsychiatric Sequelae of a Frontal Lobe Stroke and Review of the Literature

Poster Presenter: Ryan P. Schwer, D.O.
Co-Authors: Landon S. Frost, Andrew Buchholz

SUMMARY:
Mr. X is a 59-year-old retired male with past medical history of COPD, GERD, HLD, HTN, Alcohol Use Disorder, and Tobacco Use Disorder who presented to emergency department with a 1-2 day history of right shoulder and leg weakness culminating in a fall witnessed by his wife as well as a 3-4 day history of acute behavioral changes, reported by his wife as significantly increased agreeableness and pleasantness. The patient's wife stressed the importance of this behavioral change, noting his longstanding history of aggressiveness and argumentativeness – behaviors and attitudes exacerbated by his 30-year history of consuming 10-12 beers and smoking 1-2 packs of cigarettes daily. During his interview in the ED, the patient reported that he lacked desire to consume alcohol or smoke cigarettes since the onset of his symptoms. On physical exam, the patient was noted to appear disheveled, looking older than stated age, and urinated on himself in the ED. His demeanor was pleasant, though somewhat docile, with poverty of speech. He exhibited a course tracking nystagmus in leftward gaze as well as a right facial droop, right HF/KF/DF 4/5 strength, and an ataxic native gait. Non-contrast head CT in the ED was remarkable for low attenuation in the left basal ganglia and left frontotemporal region. The patient was admitted to the Cardiology unit for subacute stroke workup. An MRI/MRA was performed, which demonstrated subacute watershed infarction in the left ACA/MCA distribution, as well as in the left caudate nucleus. Also remarkable, was an occlusion of the left internal carotid artery from the jugular bulb to the Circle of Willis, as well as a caudate lesion, thought to be secondary to occlusion of the Recurrent Artery of Heubner. Throughout the course of his hospitalization, Mr. M remained calm, polite, and docile. He denied desire to consume alcohol, although endorsed slight desire to smoke, which was controlled with NRT. Patient's wife maintained that this was a marked change in his personality and previous behavior. Extended tracking of this patient demonstrated that these behavior changes and neuropsychiatric sequelae, including abstinence from alcohol and tobacco, remained and were likely permanent. In this poster, we discuss the unique neuropsychiatric manifestations of this patient's

frontal lobe stroke and contrast it to other potential sequelae that can arise from frontal lobe lesions. We pay special attention to the neuroanatomy of the frontal lobe and discuss how the location of the lesion impact behavior, cognition, and executive function. Lastly, although this patient's motor symptoms made imaging a logical next step, we review the importance of head imaging in patients with acute or subacute behavioral abnormalities without clear etiology on history, physical exam, and lab work up.

No. 28

Effect of ECT on Catatonia and Its Possible Etiologies and Comorbidities

Poster Presenter: Sean Lowell Wilkes, M.D., M.Sc.

SUMMARY:

Background: While Parkinsonism is not uncommon in schizophrenia patients treated chronically with antipsychotic medications, comorbid idiopathic Parkinson's disease in such patients is relatively rare. This can present a number of challenges in both diagnosis and selection of appropriate treatments. In addition, the emergence of catatonic symptoms and medical comorbidities and associated delirium can also complicate the diagnostic picture, and may require additional measures for the effective treatment of these multiple comorbidities. As demonstrated with our patient, electroconvulsive therapy (ECT) is one available modality known to have some effectiveness in the treatment of schizophrenia, Parkinson's disease, catatonia, as well as delirium which in its hypoactive form can present as catatonia. **Case:** GS is a 62-year-old male veteran with a history of schizophrenia, Parkinson's disease, and BPH, who was admitted to the medicine ward with suspected anticholinergic toxidrome secondary to overdose of his prescription quetiapine. He had recently changed medications from clozapine, with which he had been treated for several years to quetiapine. He remained on the medicine service due to poor oral intake needing either IV fluids or a NG tube, and urinary retention thought to be the result of the anticholinergic toxidrome in combination with his already extant BPH. He needed an indwelling Foley's catheter to relieve him of his urinary retention. While hospitalized, he developed worsening symptoms of psychosis and soon became acutely catatonic. It was unclear if he was also delirious and may have had a seizure in view of his behavior of staring into space. He was given a trial of aripiprazole to treat his psychosis, lorazepam for catatonia, and IV valproic acid for possible delirium and seizure. All these interventions had minimal effect on his symptoms. A trial of amantadine led to increased verbalization, but worsening of psychotic symptoms. He was started on clozapine with slight improvement, but the patient essentially remained in bed and would often refuse treatment. The patient was then referred for ECT and his symptoms improved drastically. **Discussion:** The diagnosis of catatonia in hospitalized patients with medical comorbidities can be challenging, as can the selection of appropriate treatment in such a patient with comorbid schizophrenia, Parkinson's disease, and possible hypoactive delirium. Here we discuss the diagnosis of catatonia and its possible etiologies, which can share a number of overlapping clinical features. Furthermore, we discuss the indications for ECT in this patient, which has demonstrated some efficacy in the treatment of catatonia and its possible etiologies including schizophrenia and delirium, as well as Parkinson's disease.

Impulse Control Disorder in an Otherwise Normal Healthy Female With Agenesis of the Corpus Callosum: A Case Report With Literature Review

Poster Presenter: Sridhar Babu Kadiyala, M.D., Ph.D.
Co-Author: Miles E. Driscoll, M.D.

SUMMARY:

The Corpus Callosum is both the major and largest myelinated fiber tract containing more than 200 million axons connecting both cerebral hemispheres and is responsible for integration of various modalities of information between hemispheres. Agenesis of the corpus callosum is a congenital defect and affects the growing fetus in the first trimester which can occur either in isolation or with other genetic abnormalities leading to various neurodevelopmental disorders. Several neuropsychiatric syndromes have been identified in patients with agenesis of corpus callosum ranging from small monogenic changes to significant chromosomal changes. Agenesis of the corpus callosum, along with other abnormalities, can lead to

various developmental issues including seizures, intellectual disability with learning problems requiring special education, developmental and gross motor delays. Here we present a case of agenesis of corpus callosum in a twenty seven year old female that went undiagnosed for twenty two years. During this period, the patient was asymptomatic other than a learning disability requiring special education throughout her academic career. As the patient developed gradual weakness and left sided tremor, magnetic resonance imaging (MRI) of the brain was obtained, which revealed complete agenesis of the corpus callosum with dysplastic left cerebellar hemisphere. The patient was referred to psychiatry for obsessive compulsive traits and was subsequently diagnosed with impulse control disorder with poor insight and judgment that improved with behavior modification and medication. Although medication trials with various atypical antipsychotics improved her behavior, she developed persistent prolactinemia, galactorrhea and amenorrhea. Previous studies have shown that corpus callosum size appears to be play an important role in the emergence of psychiatric illnesses like schizophrenia; however, controversy exists as patients with agenesis do not consistently present with schizophrenia. Therefore, we hypothesize that the emergence of poor impulse control with obsessive traits in our patient appears secondary to the sequela of the decreased integration of complex sensory information between the cerebral hemispheres. Understanding how the brain functions in patients with agenesis of corpus callosum may provide valuable insights into how sensory information is processed and potential compensatory mechanisms involved. Functional MRI (fMRI) or positron emission tomography (PET) studies will be of crucial value in elucidating the mechanisms of physiological brain functioning and developing better therapeutics.

No. 30

Psychiatric Manifestations of Schizencephaly: A Primer and Systematic Review

Poster Presenter: Suzanne Lippman

SUMMARY:

Background: Schizencephaly, a rare congenital disorder, is defined as a gray matter-lined cleft extending from the pial surface to the ventricle of the brain. It is classified as either bilateral or unilateral and either closed-lip (type 1) or open-lip (type 2). Depending on the areas of the brain involved, patients have a variety of clinical presentations, including those of psychiatric nature. **Objective:** (1) To qualitatively and systematically review thirteen cases of psychiatric manifestations of schizencephaly **Methods:** We performed a systematic review of the literature following the PRISMA guidelines and used the PubMed, PsycINFO, and Cochrane database of systematic reviews to identify cases of psychiatric manifestations of schizencephaly. The main search term was "schizencephaly" and an accessory item was added, either "psychosis," "psychiatry," "psychiatric manifestations," "schizophrenia," "bipolar," "mania," "depression," "irritability," "anxiety," "impulsivity," or "temper." Inclusion criteria consisted of case reports of schizencephaly with psychiatric manifestations written in English. **Results:** We identified a total of eleven separate articles with a total of thirteen unique case reports of psychiatric manifestations of schizencephaly in children and adults. 69% of patients had history of an episode of psychosis, 31% had a history of a depressive episode, 31% had a history of manic or hypomanic episode, 8% had a history of obsessive-compulsive disorder, and 15% had a history of substance use disorder. Regarding type of schizencephaly, 54% had unilateral, closed-lip type, 15% had unilateral, open-lip type, 23% had bilateral, closed-lip type, and 8% had bilateral schizencephaly with open-lip type on the right side and closed-lip on the left. Also, 69% of cases were male and 31% were female. Associated manifestations included 39% of cases with any history of seizures, 77% with any motor deficit, and 62% with any cognitive deficit, including learning, memory, and attention. **Discussion:** Schizencephaly can present with variable psychiatric manifestations, with associated seizures and motor and cognitive changes. Rupture of intracortical connections caused by schizencephaly may have contributed to the assorted psychiatric manifestations seen in these patients. Brain imaging showed involvement of each lobe of the cerebral cortex in multiple cases, often with the defect extending to the corpus callosum and lateral ventricle. Future research should investigate specific

brain circuit abnormalities that contribute to these psychiatric presentations.

No. 31

Challenges in Dealing With Homicidal Ideations in a Patient With Recent Stroke

Poster Presenter: Mariyah Z. Hussain, M.B.B.S.
Co-Author: Jeffrey I. Bennett, M.D.

SUMMARY:

Case: The patient is a 56 year old Caucasian male, with a past history of thalamic stroke five years ago and a recent right thalamic stroke presented to the emergency department with homicidal ideations toward his wife in the context of a trivial matter. Past psychiatric history was significant for Major Depressive Disorder, which was diagnosed post-stroke along with personality changes. Prior to the recent stroke, patient was described as a calm and friendly individual who held no prior psychiatric history. Following his stroke several months ago, he was admitted to the neurology. This hospitalization was complicated due to altered mental status possibly emerging from uremic encephalopathy as he has chronic kidney disease. Later because of his elevated CRP and ESR, a brain biopsy was performed but no indication of vasculitis was evident. An MRA Head and Neck demonstrated possible of right vertebral artery stenosis. Post craniotomy, there was wound dehiscence and MRSA infection requiring ICU admission. Following ICU discharge, the patient became verbally threatening and subsequently was physical aggressive. When the patient refused to go to a skilled nursing facility, an ethics consultation was requested. Psychiatry was consulted to assess for decision making capacity. Psychiatry was re-consulted when the patient started expressing homicidal ideation toward his wife during the hospitalization. Despite this situation, his wife had agreed to take him home, but soon after discharged returned to the emergency department after she was struck twice by him. Again, after evaluation, he was discharged home upon the request of his wife. A month later, he became minimally responsive after an apparent seizure. He was admitted and an EEG was normal, but levetiracetam was initiated prophylactically. He was discharged home, but returned to the ED in a month with homicidal ideation toward wife. At that time, he was alert and oriented; had a depressed mood and irritable affect. He lacked insight into his illness and was not remorseful of the threats to his wife or how this situation could lead to a more serious outcome. A psychiatric admission was deemed necessary. Conclusion: Following stroke, emotional disturbances are common which has led to the emergence of more sophisticated terms such as post-stoke emotional incontinence and post-stroke anger proneness. However, it is of note when homicidal ideation arise such as in this case, it can result in dramatic caregiver burden, diminished quality of life, and diagnostic challenges. We discuss the challenges in dealing with homicidal ideation which reduces the successful outcomes of rehabilitation therapy. We will present brain images and will further discuss other conditions which could have led to his homicidal ideations considering this is rare with thalamic infarcts.

No. 32

Dystonic Reaction Following Administration of Venlafaxine

Poster Presenter: Mariyah Z. Hussain, M.B.B.S.

SUMMARY:

The current literature on SSRI induced movement disorders include case reports on dystonia, akathisia, akinetic-rigid syndromes, and dyskinesias. Venlafaxine, a serotonin-norepinephrine reuptake inhibitor, has been reported as etiologic in association with focal, segmental dystonia. We report a case of a more generalized dystonic reaction associated with the use of venlafaxine, which we believe is unique. In addition, this case has several confounding factors including the presence of substance use, tremors, diarrhea, neuropsychological abnormalities hence leading to differential diagnosis of generalized dystonia, a serotonin syndrome, psychogenic dystonia, as well as venlafaxine-induced dystonia. As such, this case is an example of the diagnostic challenges posed by the emergence of dystonia in the psychiatric patient population. A 25 year old single Caucasian female with a past psychiatric history of Major Depressive Disorder, was admitted to the psychiatric unit secondary to suicidal ideations. Her history was also significant for use of daily IV heroin for many years. She was initiated on Venlafaxine XR 37.5mg once

daily for depression and anxiety. Patient had a trial of Venlafaxine XR in the past and this has served to be beneficial without experience of any adverse outcomes. The following day of starting Venlafaxine, patient was noted to have significant visible involuntary neck tremors which persisted for two days. This was in addition to lower extremity muscle spasms and ataxia. At this time, patient also complained of nausea and diarrhea. Neurology service was consulted and upon conduction of MRI cervical spine, it revealed no significant findings. Lab findings were unremarkable except for a positive C difficile test which was managed with appropriate antibiotics later. Patient was noted to have hyperreflexia in both lower extremities but sensations were intact. Pronounced ataxia in bilateral lower extremities in heel-to-shin test was observed along with an unsteady tandem gait. Concerns regarding serotonin syndrome, Venlafaxine induced dystonic reaction, psychogenic movement disorder and heroin induced withdrawal were considered. Venlafaxine was discontinued and thereafter, the tremors significantly improved. She was switched to Bupropion, which the patient tolerated well. Further hospitalization was notable for emergence of hypomanic symptoms, which prompted the addition of Lamotrigine. Venlafaxine is a novel antidepressant that holds prominent anti-depressant and anti-anxiety properties and acts on both serotonin and norepinephrine reuptake inhibition. This case illustrates the complexity of diagnosing a serotonin syndrome versus a medication induced dystonic reaction in a setting of opiate withdrawal; also raising concerns for metabolic causes. This poster will focus on challenges involved in reaching to an appropriate diagnosis to prompt appropriate treatment measures in a similar setting.

No. 33

Clozapine Prescribing Trends in a General Hospital in Singapore: The Story Over Nine Years

Poster Presenter: Hui Yi Ong

SUMMARY:

Background: Clozapine is widely recognised as the most efficacious antipsychotic in treatment-resistant schizophrenia. However, its side-effect profile and need for regular blood monitoring, as compared to newer second-generation antipsychotics, may render it less desirable for patients, particularly the elderly. This study aims to describe the prescribing trends of clozapine in a general hospital in Singapore from 2005-2013. Methods: Data was extracted retrospectively from the computerised prescription records of Tan Tock Seng Hospital, Singapore. This hospital has a Psychiatry Medicine department that focuses primarily on consultation liaison, but also manages mild to moderate illnesses falling under the purview of general psychiatry. All patients who received clozapine in 2005, 2007, 2009, 2011 and 2013 were selected and stratified based on age, gender and clozapine dose. Results: The total number of patients prescribed clozapine increased from 48 in 2005 to 93 in 2013 (94% increase). Of the total number of patients on clozapine, an average of 39.1% were male and 60.9% female. The mean age of patients increased from 42 years in 2005 to 50 years in 2013. The total number of elderly (?60) prescribed clozapine increased, from 4 in 2005 to 15 in 2013 (275% increase). The mean daily dose increased from 88.9mg in 2005 to 135.3mg in 2013, and the dose range increased from 6.25 – 350mg in 2005 to 12.5 – 850mg in 2013. Only a small proportion received daily doses in excess of 300mg, albeit increasing in number over the years (n=2 (4.2%) in 2005 vs n=10 (10.8%) in 2013). Those receiving <100mg/day daily dosage remained the largest proportion over the years (64.6% in 2005 and 44.1% in 2013). Discussion and conclusion: Despite valid concerns about the safety profile of clozapine and the emergence of new antipsychotics with more favourable side-effect profiles, clozapine use (both in terms of number of patients prescribed clozapine and dose of clozapine prescribed) is still increasing, indicating that it remains an integral part of the treatment of schizophrenia. There is a clear preference to maintain patients on lower dose ranges. Also, the absolute number of patients on clozapine remains low, perhaps reflecting a reluctance in the initiation of clozapine by clinicians. Further studies need to be carried out to identify any barriers to clozapine initiation and maintenance.

No. 34

Case of Acute Reversible Hyperglycemia With Olanzapine Administration in Non-Diabetic Patient

Poster Presenter: Jatinder Singh, M.D.

Co-Author: Harsimar Kaur

SUMMARY:
Introduction In our clinical practice, increasing number of patient s are being prescribed second generation antipsychotics for increasing number of indication including nonpsychotic patients, mainly due to their unmatched efficacy which tends to outweigh the metabolic side effects(1). The usual indicator of these side effects remains weight gain (BMI), with the low incidence of actual monitoring(2) despite a call for such regular monitoring from current guidelines. To make things worse there is now evidence of weight independent adverse metabolic changes like glucose intolerance and dyslipidemia associated with SGA, which are more acute in nature(3), likely to have unique mechanism of action, manifest before any change in weight, could possibly have dose relationship and usually missed in young adults without any comorbidities. CASE Our patient is 26-year-old African American female with the diagnosis of a Schizoaffective disorder. There was no history of Diabetes in this patient as per previous available record. Her first ever exposure to Antipsychotics, Olanzapine 10 mg, and Quetiapine 700 mg was in Feb 2014 while she was incarcerated in Prison and later transferred to an inpatient facility. She was reportedly compliant with medications. Regular Blood glucose done on admission was within normal limits at 95 mg/dl (45 to 99). She was subsequently discharged home on Olanzapine 10 mg QAM and 12.5 mg QPM. Again admitted to inpatient facility due to relapse of her schizoaffective disorder She was restarted on Olanzapine and which was built up to 20 mg. Her blood Glucose continued to rise in relation to olanzapine until it reached 299 mg /dl when she required insulin units to lower it down. The decision to discontinue and cross taper olanzapine was made and the Patient blood glucose returned to normal levels once olanzapine was discontinued and remained within normal limits till discharge from hospital From the above data, it seems patient was sensitized to olanzapine in terms of Blood Glucose dysregulation on restarting on this current admission and there was kind of dose relationship observed in above data and it returned to near normal on discontinuation. On 1 years follow up of the patient, she remains nondiabetic and on antipsychotic treatment Discussion: There has been increasing recognition that atypical antipsychotics are associated with an increased incidence of obesity, type 2 diabetes, and other metabolic side effects. Olanzapine specifically has been associated with severe metabolic consequences, including weight gain and increases in fasting glucose and insulin (4, 5). These effects have been observed and reported in a time frame of weeks and months rather than hours or days in clinical studies. Future prospective clinical studies focusing on identifying which reliable metabolic alterations might be useful as potential screening tools for assessing patient susceptibility to acute hyperglycemia, associated complications.

No. 35

An Undocumented Interaction Between Olanzapine and Lopinavir-Ritonavir Causing Severe EPS

Poster Presenter: Jeffrey Parker Burrow, M.D.

SUMMARY:
Introduction: Extrapyramidal Symptoms are symptoms seen sometimes as a reaction to antipsychotics. Symptoms are similar to those of Parkinson's disease due to the similarity of a dopamine blockade in the nigrostriatal tract to the loss of dopaminergic neurons from the substantia nigra. The symptoms include bradykinesia, cogwheel rigidity, resting tremor, and other parkinsonian symptoms. The typical antipsychotics have been reported to have a risk of up to 10% of causing some form of EPS, and the atypical antipsychotics have a much lower incidence of EPS. Reports of the agent used in this case, IM olanzapine, report it to be around 2-4%. In this case an unreported interaction between an injectable olanzapine and HIV medication may have led to higher than intended level of olanzapine and thus a severe EPS reaction on presentation to a psychiatric unit. Case: CL is a 50 year old man with schizoaffective disorder-bipolar type who presented with worsening depression and psychosis. He had been previously treated before in the same hospital in 2013, and stabilized on risperidone without side effects. He presented in 2017 to the ED with symptoms of depression, SI, and AVH. He was not on any psychiatric medications at this time but was taking lopinavir-ritonavir, metoprolol, and lisinopril. Patient was given 10 mg of IM olanzapine in the ED, continued on his current

medications, and transferred to inpatient psychiatry the next morning. On presentation to the unit patient was in moderate distress and unable to speak per staff. When examined patient was in bed with rhythmic bilateral contractions of lower limbs, upper limbs, neck and jaw muscles. On passive movement he had cogwheel rigidity. He was given 50 mg IM of diphenhydramine, and had some response, able to speak more easily, though continued to have significant resting tremors. This was repeated. His symptoms continued to abate slowly and he continued to have rigidity and tremor. He was given 4 mg of PO trihexyphenidyl in 2 doses later that evening, and his symptoms began to abate. The next morning patient had some residual rigidity in his jaw muscles leading to difficulty speaking. Trihexyphenidyl was tapered over the next 3 days. He had complete resolution of EPS before being transferred to a facility that could provide ECT. Discussion: This case was an interesting and severe presentation of EPS acutely after IM olanzapine. Initially patient had no side effects, but less than 16 hours later there was progressive EPS. The patient had been on antipsychotics in the past including haloperidol, risperidone, and a trial of olanzapine that failed due to weight gain. He had never had EPS and the previous use of olanzapine was not on this antiviral regimen. No drug interaction database used indicated that this combination would lead to EPS or elevated drug levels, but a review of the CYP enzymes involved showed that both antivirals inhibit 1A2 and 2D6 which process olanzapine as a substrate.

No. 36

The Use of SSRIs in Post-Ischemic Stroke Motor Recovery: A Systematic Review and Meta-Analysis

Poster Presenter: Mark Kvarta, M.D., Ph.D.
Co-Authors: Bhinna Pearl Park, M.D., Ellen Breen, M.D., Michael Stephen Peroski, D.O., Seth S. Himelhoch, M.D.

SUMMARY:
Context: Motor deficits are among the most common deficits caused by stroke. Improvement in motor function is a crucial part of stroke recovery which may lead to improved quality of life for patients. Objective: To assess the effects of SSRIs versus placebo on the motor function of adults with recent ischemic stroke. Data sources: English-language articles from Jan 1980 through Sept 2016 were searched in two electronic databases, PubMed and PsychINFO. Study Selection: The criteria for inclusion required studies to be randomized placebo controlled trials of treatment with SSRIs vs placebo in patients who suffered an ischemic stroke. The studies were restricted to samples of adults aged 18 or older, and had to include scores on a scale measuring motor function. Studies in which SSRIs were used only to treat depression were excluded. The final search resulted in three studies. Data extraction: Two authors independently reviewed them for meeting eligibility criteria. The kappa statistic was 0.856, consistent with good agreement. Results: This quantitative meta-analysis showed that treatment with an SSRI post-stroke significantly improved motor function in stroke patients as compared to placebo. The overall effect size was medium and was statistically significant with a standard mean difference of 0.573 (95% confidence interval of 0.243-0.903) (p=0.001). Heterogeneity was not statistically significant (p=0.349). Conclusion: The statistically significant moderate effect of SSRIs on post-stroke motor improvement suggests that this is a potentially effective intervention worth further exploration, especially in a population well known to have significant depressive symptoms and motor impairment.

No. 37

Delayed-Onset Choreoathetosis as a Complication of Lithium Toxicity

Poster Presenter: Michael Thomas Ingram, M.D.
Co-Author: Adedapo B. Williams, M.D.

SUMMARY:
RS is a 59-year-old Caucasian male who called 911 due to acute onset confusion, coarse tremors, slurred speech, ataxic gait, and generalized weakness. He had a history of bipolar 1 disorder managed with lithium and escitalopram. He had no previous history of tardive dyskinesia, chorea, or any other movement disorder. His past medical history was significant for hepatitis B, diabetes mellitus (type II), peripheral neuropathy, and cirrhosis. On admission, his lithium level was elevated to 4.3 and his vital signs were unremarkable except for bradycardia. A general physical examination

revealed altered level of consciousness and psychomotor agitation with no focal neurological deficits or visible signs of head trauma. RS was lethargic, oriented only to his name, and appeared thin, cachectic, and unkempt. His speech was slurred and incomprehensible. There were coarse tremors of his upper and lower extremities as well as "involuntary jerky movements" of all four extremities described as non-repetitive and nonrhythmic. Laboratory studies were significant for pancytopenia, mild hyponatremia, slightly elevated ammonia level, and signs of acute kidney injury. Urine drug screen and blood ethanol level were unremarkable. Telemetry revealed sinus bradycardia with intermittent episodes of atrial fibrillation, no ST changes, and a QTc of 532. Chest X-ray showed no acute disease. MRI with and without contrast showed mild global cortical atrophic changes with no evidence of brain stem pathology or acute changes. Emergency hemodialysis was initiated with normalization of his lithium level and metabolic panel within 36 hours. Despite slow resolution of his bradycardia and confusion, RS developed slow athetotic movements of his hands and feet bilaterally in addition to repetitive tongue protrusion, jaw movements, grimacing, and eye blinking. These movements slowly resolved over the next 48 hours with significant improvement in his mental status. In this poster, we present a rare case of delayed-onset choreoathetosis as a complication of lithium toxicity and offer recommendations for management based on clinical experience and a systematic review of related cases in the literature. Lastly, we describe a theoretical pathophysiological mechanism to explain the relationship between lithium toxicity and movement disorders.

No. 39
Ondansetron to Treat Tardive Dyskinesia: A Case Report
Poster Presenter: Nicole Christina Rouse, D.O.

SUMMARY:
Ms. T, a 55-year-old African American female with a past psychiatric history of bipolar I, obsessive compulsive disorder, and generalized anxiety disorder, presented to the neurology clinic with history of tardive dyskinesia for 7 months. Treatment with Risperdal was initiated 3 months prior to onset of orofacial dyskinesia. Medication trials of Cogentin, Benadryl, artain, gingko and klonopin either did not improve her symptoms or she endured adverse effects. Tetrabenazine was discussed with Ms. T, however was contraindicated secondary to her significant history of bipolar-depression and suicidal ideations. She was then started on ondansetron 4 mg daily as a trial to treat her tardive dyskinesia. In a follow-up appointment 4 weeks later, she reported significant improvement of her symptoms. Tardive dyskinesia involves involuntary movements of facial, limb, and truncal muscles, and a rare adverse effect of dopamine antagonist medications: typical antipsychotics, risperdal, metoclopramide and pimozide. In the nigrostriatal dopamine pathway, receptors become upregulated with prolonged use of dopamine antagonist activity and may result in abnormal involuntary movements. Serotonin and dopamine have an interesting relationship in this pathway, and 5-HT antagonist activity has been reported to reduce tardive dyskinesia symptoms. Ondansetron is a selective 5-HT3 antagonist with documented cases of success in treatment of tardive dyskinesia. In this poster, we discuss the relationship between serotonin and dopamine in the nigrostriatal pathway in treatment of tardive dyskinesia, often an irreversible and difficult-to-treat disorder.

No. 41
Improvement of Smell and Taste With Discontinuation of Buprenorphine/Naloxone
Poster Presenter: Ruchi Sood

SUMMARY:
Introduction: Buprenorphine/naloxone, a partial opioid agonist, has been described to induce smell and taste aversion (Lonergan et al., 2011) and impairs chemosensation (Mizera et al., 2016). Discontinuation of buprenorphine resulting in enhancing smell and taste has not heretofore been described. Two such cases are presented. Method: Case 1: A 36 year old, right-handed married male

had a 10-year history of opioid abuse including fentanyl, acetaminophen/oxycodone and heroin. A few days prior to presentation he was on a variety of substances including 8 mg buprenorphine/2 mg naloxone every 12 hours, a fentanyl patch 100 mg every 48 hours, snorting heroin 1/2 gram each day, smoking marijuana daily and cigarettes one pack per day. He was undergoing withdrawal manifested by insomnia, fatigue, anxiety, and poor appetite. Results: Clinical Opiate Withdrawal Scale: 21 including diaphoresis with sweat streaming off face, constant rhinorrhea, lacrimation, vomiting, diarrhea, and frequent adventitious movements. After being placed on buprenorphine/naloxone sublingual 4 mg/1 mg twice a day, he observed a total absence of his ability to smell and taste. Within 2 days of suddenly discontinuing buprenorphine/naloxone, his smells and taste returned to 50% of normal. Within a week of him restarting buprenorphine/naloxone, his ability to smell and taste disappeared again. Case 2: A 34 year old right-handed married female with 10 year history of opioid dependence (with past hospitalization for detoxification) presented using 100 microgram patch of fentanyl every 48 hours, snorting heroin 0.5 grams everyday, and smoked one pack per day of cigarettes, with complaints of impaired memory. Results: Clinical Opiate Withdrawal Scale: 8 including rhinorrhea, lacrimation, pupils moderately dilated, increased irritability and anxiousness and mild diffuse discomfort. After being placed on buprenorphine/naloxone 8 mg/2 mg twice a day, she observed a reduced ability to smell and taste to 70% of normal. Within several days of stopping buprenorphine/naloxone, her smell and taste returned to 95% of normal. After restarting the buprenorphine/naloxone her smell and taste dropped down again to 70% of normal. Within a week of her restarting buprenorphine/naloxone, her ability of smell and taste disappeared again. Discussion: The use of opiates has been reported to alter taste (Schiffman, 2015) and reduce smell (Lotsch et al., 2012). Mizera specifically listed buprenorphine/naloxone as an origin for chemosensory loss (Mizera et al., 2016). However, the discontinuation of buprenorphine/naloxone has not previously been described to improve smell and taste. Maybe the reduction in olfactory function was partial and due to a reduction in specific G protein-coupled receptors (GPCRs) with reduced cAMP as the second messenger (Lotsch et al., 2012). Given the above, a trial of buprenorphine/naloxone in those with hyperosmia and hypergeusia may be warranted.

Khat-Induced Psychosis Treated With Risperidone
Poster Presenter: Bechoy Abdelmalak, M.D.
Co-Authors: Ashraf Elshafei, M.D., Ronnie Swift, M.D.

SUMMARY:
Mrs. E. is a 35 year-old Yemeni female, Arabic speaking, with a past psychiatric history of self-reported Schizophrenia and 4 prior inpatient psychiatric hospitalizations, who presented to our mental health clinic with a complaint of "I am hearing voices and they are talking to each other." Patient reported an extensive history of Khat use and poor response to multiple treatment regimens, including Depakote, Xanax, Haldol, Abilify and Zyprexa. Patient reported that usually she hears a female voice commanding her to use Khat, "To get better." She was started on Risperidone 0.5mg at bedtime, and started to show improvement within 4 weeks, along with a decreased need for Khat use. She was also referred to Dental Service due to brown staining and discoloration of her gums, cracks in here teeth and dental structural damage secondary to her Khat use. Khat is a flowering evergreen shrub native to East Africa and the Arabian Peninsula. The young and tender leaves of the khat tree (Catha edulis forsk), known as "khat," "qat," or "miraa," are traditionally chewed in social settings because of their stimulating effects. The main psychoactive component of khat leaves is cathinone (S (-) alpha aminopropiophenone), which resembles amphetamine in chemical structure and affects the central and peripheral nervous system. Users, which include pregnant women simply chew the green khat leaves and keep a ball of partially chewed leaves against the inside of their cheek. Some khat users also smoke the drug, make it into tea, or sprinkle it on food. We report here a case of exacerbation of psychotic symptoms attributed to khat chewing, which responded to Risperidone.

Erythema Multiforme Associated With the Combined Use of Lamotrigine and Topiramate

Poster Presenter: Bechoy Abdelmalak, M.D.
Co-Authors: Norma Dunn, M.D., Ronnie Swift, M.D.

SUMMARY:

Ms. K. is a 28 year-old Caucasian female with past medical history of migraine headaches and a past psychiatric history of Bipolar disorder and marijuana use, who presented to the outpatient psychiatry service with racing thoughts, impulsivity, and mood swings. She was started on lamotrigine and the dose was gradually increased, from lamotrigine 25mg daily for 2 weeks, then to lamotrigine 50mg daily for 2 weeks, and then lamotrigine 100mg daily thereafter. Topiramate was started 10 weeks after starting lamotrigine to address migraines (Topiramate has been also used alone or in combination with bupropion to decrease marijuana cravings). Topiramate was started with 50mg at bedtime for 2 weeks and then increased to 50mg twice a day. Three weeks later, patient noted multiple small pruritic papules on her arms that spread to the trunk area that did not respond to Medrol dose pack following her visit to urgent care. Patient stated that her rash started initially when she accidently took 2 tablets of lamotrigine 100mg, and then later started to progress again when she accidently took another 2 tablets of lamotrigine the next day. Dermatology consult was placed and patient was diagnosed with Erythema Multiforme secondary to lamotrigine or topiramate. The rash slightly improved when lamotrigine was discontinued, but resolved once topiramate was discontinued. Erythema Multiforme (EM) is an uncommon, acute type IV hypersensitivity skin reaction characterized by a skin eruption, with symmetric erythematous lesions of the skin or mucous membrane possibly mediated by the deposition of immune complex (mostly IgM) in the superficial microvasculature of the skin and the oral mucous membrane. Erythema Multiforme (EM) is associated with certain infections (particularly herpes simplex and mycoplasma pneumoniae), medications, and other various triggers. Medications like lamotrigine and topiramate are metabolized to toxic metabolites, which are subsequently detoxified in most individuals. However in predisposed patients with a genetic defect, the metabolite may bind covalently to proteins. In some of these patients, the metabolite- protein adduct may trigger an immune response, which may lead to a cutaneous adverse reaction. Clinical manifestations of drug-induced skin reactions include a wide range of symptoms, from mild drug-induced exanthemas to dangerous and life-threatening generalized systematic reactions. We report one case of generalized EM in which the combined use of lamotrigine and topiramate seems to be the precipitating factor.

Mirtazapine-Induced Violent Dreams

Poster Presenter: Bechoy Abdelmalak, M.D.
Co-Authors: Richard Gersh, M.D., Ronnie Swift, M.D.

SUMMARY:

Mr. T. is a 53 year-old African-American veteran male, with a past psychiatric history of major depressive disorder and PTSD, including multiple prior hospitalizations for suicidal behavior, who presents to the mental health clinic for depressed mood, lack of motivation, crying spells, sleeping difficulties, nightmares and flashbacks. He was started on prazosin 2mg at bedtime and mirtazapine 15mg at bedtime. Two weeks after initiating treatment, patient reported an increase in the frequency of nightmares from 1 every 2-3 days to “almost daily”, without improvement in his sleep pattern. Mirtazapine was increased to 30mg at bedtime. He returned to the mental health clinic 4 days later, reporting “daily weird and violent dreams.” He was instructed to discontinue mirtazapine and was started on sertraline with resolution of violent dreams and reduction in frequency of nightmares within one week. Mirtazapine is a tetracyclic noradrenergic and specific serotonergic antidepressant that is widely used in the treatment of depression. It acts by blocking a-2 receptors on noradrenergic neurons and enhancing norepinephrine release. Increased levels of norepinephrine act on a-1-adrenoceptors on serotonergic cell bodies, increasing serotonergic firing. Mirtazapine also is a very strong H1 receptor inverse agonist and as a result, it can cause powerful sedative and hypnotic effects. Mirtazapine, on the other hand, has been documented to show sleep-

promoting action by increasing total sleep time, sleep efficiency and slow wave sleep. Nightmares occur only in rapid eye movement (REM) sleep. Most antidepressants suppress REM sleep; hence, nightmares are not a commonly reported side effect of therapy with antidepressants. Sleep disorders are extremely rare adverse events with mirtazapine and we are reporting a case of mirtazapine worsening violent and strange nightmares that required stopping the associated medication.

No. 46

Comparison of Bipolar Detection Instruments Among Patients With Mood Disorders and Cluster B Personality Disorders

Poster Presenter: Sergio D. Apfelbaum, M.D.

SUMMARY:

Apfelbaum S (MD)*, Regalado P (PhD)+, Herman L (MD)*, Gagliesi P (MD)+. Background: Scientific literature has well established that Bipolar Disorder (BD) is frequently under-diagnosed. Studies have reported a ten-year breach between disorder onset and its proper diagnosis, in a large proportion of BD patients. However, many authors highlight the bipolar spectrum disorders over-diagnosis in patients with personality disorders, particularly cluster B. The present study compares the efficiency of several BD screening and assessment instruments to detect BD in a sample of clinical outpatients. Methods: The study included patients aged 18 to 65 years who gave written informed consent. They had to meet DSMIV R diagnostic criteria for a Mood Disorder and/or cluster B Personality Disorder. A sample of outpatients (n = 81) were assessed and arranged in 4 diagnostic groups: Mayor Depression (MD n=24), Bipolar Disorder (BD n=18), Cluster B Personality Disorders (PD-B n=19) and comorbidity of BD and PD-B (n=20). Patients who entered the study completed the Mood Disorder Questionnaire –MDQ, and Bipolar Spectrum Diagnostic Scale -BSDS at the time of inclusion, and patients' therapists completed the Bipolar Index -BI and Gahemi's Bipolar Spectrum Criteria. The DSM-IV R diagnoses were evaluated with two semi-structured interviews (MINI and SCID-II) for axis I and axis II disorders respectively, rated by a psychiatrist or psychologist blind to the results of the screening questionnaires. The instruments were compared by their Sensitivity, Especificity, Positive and Negative Predictive Values and Positive and Negative linkhood ratio. Results show good sensitivity and specificity values for the MDQ and BSCS (specificity: 0.79 vs 0.77; sensitivity 0.74 vs 0.71 respectively) and similar positive predictive values (PPV: 73%) for both instruments to identify BD. The Bipolarity Index, with an ad hoc 50-cutoff point, revealed excellent sensitivity and specificity values (0.84 and 0.90) with PPV of 87%. Finally, the simultaneous implementation of both, the screening instruments (MDQ or BSDS) and Diagnostic Criteria of Bipolar Spectrum provided a notorious improvement in sensitivity detection whit some decline in specificity values and slightly decline in PPV, but also expanded the bipolar spectrum detection regardless of identifying manic symptoms. Conclusions: The concurrent utilization of MDQ and the Criterions Gahemi's Bipolar Spectrum notably increased the sensitivity for detection of BD while still maintaining reliability. The development of a questionnaire that includes screening for manic symptoms (MDQ) plus symptomatic and evolutionary characteristic of the bipolar spectrum could significantly increase the sensitivity of the screening for BD. A discussion explores the implications of the previous findings.

No. 47

A Case Report on Late-Onset Bipolar I Disorder Due to Transient Ischemic Stroke

Poster Presenter: Sumin Park
Co-Author: Angelo De Los Angeles, M.D.

SUMMARY:

Ms. F., a 56-year-old Caucasian female with a significant history of chronic uncontrolled hypertension, hyperlipidemia, long-time cigarette smoker, history of lower extremity claudication status post bilateral femoral stents and angioplasty, presents with recurrent uncontrolled aggression with manic symptoms. Prior to recent repeated psychiatric admissions, she had no psychiatric history. Given the late-onset of personality changes and manic symptoms, MRI of the head was ordered, which revealed encephalomalacia in the white matter of the right frontal lobe near the right basal ganglia and the left cerebellum. These areas have been highly associated with manic symptoms. Although the timing of the ischemic stroke cannot be

identified, the subacute presentation of personality change and the results of the imaging study makes bipolar I due to another medical condition is highly likely. A thorough stroke workup revealed 70-80% bilateral carotid stenosis on CTA. In the setting of having multiple risk factors and having had a transient ischemic stroke before age 60, she was counseled on her high likelihood of getting a life-threatening stroke and to consider carotid endarterectomy. She was started on aspirin 81mg. She was also advised to obtain workups to rule out blood clotting disorders such as Factor V Leiden, Protein C and S. Being that the mean age of onset for bipolar I disorder is 18 years, patients with no prior psychiatric history who present later in life with signs of bipolar I should undergo a thorough medical workup to rule out other medical conditions.

Using Long-Acting Injectable Antipsychotics as an Adjunct Treatment to Prevent Relapses in Rapid-Cycling Bipolar Disorder
Poster Presenter: Zaki Ahmad, M.D.
Co-Authors: Pankaj Manocha, M.D., Luisa S. Gonzalez, M.D.

SUMMARY:
Rapid-cycling Bipolar disorder (RCBD) is diagnosed when there are at least, four mood episodes in the preceding twelve months. RCBD patients are more likely characterized by manic features when compared to Bipolar disorder (BPD) patients who predominantly have depression. The annual prevalence of rapid cycling ranges from 5% to 33.3%, while the lifetime prevalence ranges from 25.8 to 43%, among all the patients with Bipolar disorder (1). Research studies indicate that apart from the traditional mood stabilizers such as Lithium, Depakote, and Carbamazepine, long-acting depot injections of first and the second generation antipsychotics (2, 3, 4), such as Haldol decanoate (5), and Risperdal Consta (6) have been used in the treatment of Bipolar Disorder. Rapid-cycling Bipolar disorder is a frequently under-diagnosed condition, which is more prevalent in women and patients with bipolar 2 disorder (7). In contrast to BPD, RCBD patients require more than a single conventional mood stabilizer like Lithium. Adding a long-acting injectable antipsychotic to Lithium or Depakote has shown to be the next best step in the management of RCBD to prevent recurrent mood episodes and subsequent re-hospitalizations in the future (8, 9). We present one such case of a 24-year-old symptomatic woman who was brought to the ER with acute mania despite having the therapeutic level of lithium. Her lithium level was 1.0 at admission. Clinicians can be confronted with treatment challenges for the prevention of recurrent mood episodes in patients who have therapeutic levels of the conventional mood stabilizers like Lithium and Depakote. We aim to review the literature on the treatment strategies for an acutely manic patient with therapeutic lithium levels.

Possible Link Between Hypogonadism and Depression in Men
Poster Presenter: Sarayu Vasan, M.D., M.P.H.

SUMMARY:
Background: Low serum concentration of testosterone hormone has been associated with several common medical conditions such as cardiovascular disease, erectile dysfunction, diabetes, metabolic syndrome, cognitive impairment, and depression. Until recently it was unclear whether the mood disorder is confounded by concurrent physical morbidity. The objective of this study is to determine whether association between serum testosterone concentration and depressed mood in men can occur when physical co-morbidity is under control. Methods: Seventy-five men aged 55-70 referred by their primary care providers for assessment and treatment of refractory depression where 1-2 adequately delivered anti-depressant medications did not lead the patient to become symptom free. The 9- Item Patient Health questionnaire (PHQ-9) was administered to study participants to assess depressed mood. Clinical depression was defined as severe, moderate severe, moderate, mild depressive symptoms and minimal depression when PHQ -9 total score was 20-27, 15-19, 10-14, 5-9, and 0-4 respectively. Results: Many the participants scored 20-27 and 15-19 on the PHQ-9 scale. Therefore their

clinical depression was characterized as severe and moderate severe depression respectively. Treatment with anti-depressant medications using adequate dose and duration, switching and combining anti-depressants as well as augmentation with different psychotherapeutic approaches such as cognitive behavioral therapy (CBT), interpersonal psychotherapy (IPT), and problem-solving therapy (PST) were used for 12 weeks. There was no improvement in depressive symptoms based upon self-report, observation, and the assessment using the PHQ-9. Total and free testosterone levels were ordered and samples collected between 8:00AM and 11:00AM. The results showed low total testosterone levels (less than 240ng/dL) and low free testosterone levels (less than 35.0pg/mL). This group of patients received intramuscular injections 200 mg every 2 weeks. Over a 10-month period, after patients maintained mid-normal physiological levels of total testosterone (290-300ng/dL) and free testosterone level (55 – 70pg/mL), follow up psychiatric visits revealed significant improvement and remission of depression as reported by self-statements, observations, mental status evaluations, and PHQ-9 scores of 0-4. Conclusion: There is causal relationship between low testosterone level and depressed mood in males. Restoring physiologic concentration of free testosterone improves mood and reduces depression. Men with clinically significant depression would have lower concentration of free testosterone than men with no depression and this association is independent of physical health. Men with depression may benefit from systematic screening of free testosterone levels. Testosterone replacement may contribute to successful treatment of men with treatment – resistant depression.

A Case of Catatonia in Pregnancy Successfully Treated With Zolpidem

Poster Presenter: Giana V. Dalben, M.D.
Co-Author: Sarayu Vasan, M.D., M.P.H.

SUMMARY:

INTRODUCTION & OBJECTIVE: First described in the literature in 1874 by Karl Kahlbaum, catatonia is a behavioral syndrome presenting as the inability to perform physical movement appropriately, such as in immobility, rigidity, mutism, posturing, excessive motor activity, stupor, negativism, staring, and echolalia. According to the DSM V, catatonia is not classified as a separate condition, but can be associated with other psychiatric conditions. To this point, the diagnosis of catatonia remains challenging given its co-occurrence with many psychiatric disorders, such as obsessive-compulsive disorder, post-traumatic stress disorder, alcohol and benzodiazepines withdrawal, schizophrenia, and bipolar disorder, as well as in somatic and medical illnesses. Prompt management with benzodiazepines or electroconvulsive therapy (ECT) are the mainstays of treatment and often offer very good prognosis and outcomes. CASE PRESENTATION: This case report describes a 21-year-old Hispanic female, G3P2, at 19-weeks intrauterine pregnancy (IUP), with catatonia and significant history of unspecified psychosis, mood disorders, and abuse of amphetamine and cannabis. DISCUSSION: After vast literature review, it is to the best of our knowledge that there have been no cases of catatonic pregnant patients treated with Zolpidem and our case would be the first case reported in the literature to date. Immediate treatment with benzodiazepines or ECT were not possible at the time of this patient's illness presentation. Numerous cases of catatonia in non-pregnant patients treated with Zolpidem, and multiple cases of pregnant patients treated with Zolpidem for non-catatonia-related illnesses are well documented in the literature. However, the use of Zolpidem was our patient's best chance of recovery from this devastating psychiatric illness without causing further harm to herself or her unborn fetus. Further, this case serves to highlight the special considerations that need to be made regarding the treatment of catatonia in pregnancy. CONCLUSION: This case illustrates the complicated course of catatonia in a pregnant patient where the two mainstays of treatment, benzodiazepines and ECT, were not viable options in her care. Due to these complexities, alternative treatment options had to be sought for the sake of the long-term wellbeing of the patient and her unborn fetus. Consequently, with the use of Zolpidem, the patient's catatonia completely resolved. Furthermore, we suggest that Zolpidem be considered as a valid, effective, and safe option in the treatment of catatonia in pregnancy. It is our hope that this case study will

contribute to further the research being conducted in this area to improve the quality of life in pregnant patients with catatonia.

No. 52

Three Cases of Suicide Phenomenon in Patients With Delusions

Poster Presenter: Samantha Cassandra Madziarksi, M.D.
Co-Author: Sarayu Vasan, M.D., M.P.H.

SUMMARY:
Background: Delusions are fixed, false beliefs that are persistent despite contrary evidence. Delusions can be seen in a multitude of different mental disorders, including Delusional Disorder which is characterized by at least 1 month of delusions without other psychotic symptoms. There is evidence that supports the content of the delusion can lead to emotional distress, ranging from anxiety to depression and subsequently attempted suicide. Case: We report three cases of delusional disorder that presents with depression following the emotional manifestations caused by the delusions, leading to attempted suicides. Discussion and Conclusion: The most significant affect change was seen in persecutory delusions, which was shown to cause depression especially when the patient associated a large power gap between themselves and the persecutor, or if the patient believes he/she deserved the punishment being enforced in the delusion (Green, 2006). There has also been extensive research addressing the increased rate of suicide in schizophrenic patients, with guilty delusions found to contribute the most to the severity of the suicidal ideation (Grunebaum, 2001). Patients diagnosed with depression that presented with delusions were also more likely to commit suicide in comparison to patients with non-delusional depression (Roose, 1983). However, only one study was found that recognized a similar rate (8-21%) seen in delusional disorder though the study was not statistically significant (Gonzalez-Rodriguez 2013). To our knowledge, very little research has been done to recognize the correlation of delusional disorder with depression and suicidal ideation. We report several cases of delusional disorder that presents with depression following the emotional manifestations caused by the delusions, leading to attempted suicides.

New-Onset Bipolar Disorder With Mania and Psychosis Associated With Frontal Lobe Cerebral Aneurysm

Poster Presenter: Anum Sameera Khan
Co-Author: Sarayu Vasan, M.D., M.P.H.

SUMMARY:
Introduction: Bipolar disorder is a complicated psychiatric illness that is still being investigated for its interesting genetic and pathophysiologic manifestations. Bipolar disorder is characterized by symptoms of mania combined with episodes of major depression or hypomania. Bipolar disorder can be classified as primarily psychiatric, or can be due to a secondary organic cause. Secondary causes of organic mania are rare, but have been observed to occur in a few case reports. In depth examination of aneurysms and cerebral hemorrhages as a cause of bipolar disorder will be further investigated in this article as it has been observed that many neuropsychiatric-based pathophysiologic pathways may play a role in exuding mood and affective phenotypes. The evaluation of patients suspected of having bipolar disorder first involves ruling out the possible medical causes. Vascular aneurysms leading to subarachnoid and intracerebral hemorrhages can also be a cause of secondary mania, and will be further investigated in the following report. Case: This case report describes a 34-year-old Latino female who had no previous psychiatric history developed new onset symptoms of bipolar disorder after a frontal lobe cerebral aneurysm rupture. Patient underwent microsurgical clipping to prevent the aneurysm from rupturing again and subsequently treated successfully with a mood stabilizer and an antipsychotic. Discussion and Conclusion: Bleeding in the brain, regardless of the type of hemorrhage, can potentially be very damaging to nearby brain parenchyma and adjacent structures. Inflammatory mediators are activated in response to blood deposition, but the cascades can also potentially augment further damage and be a source of ongoing inflammation. There continue to be postulations of altered immunological parameters that may play a role in development of

psychiatric disorders including depression, bipolar disorder, autism spectrum disorders, and schizophrenia. Mood and affective disorders are viewed, in a way, as “stress disorders” in which chronic inflammation can play a role in their development. The idea that bipolar disorder can be induced from organic causes has developed from the aftermath of neurologic insults such as traumatic brain injuries, strokes, tumors, or hemorrhages. Lesions that usually induce mania are commonly in the frontal or temporal lobes and subcortically the head of the caudate and the thalamus. A few case reports have brought light to the issue of cerebral aneurysms leading to bipolar disorder or psychosis. In summary, our case highlights the importance of looking for secondary causes of mania and psychosis and it is our hope that this case study will contribute to further research being conducted in this area to improve the quality of life in these patients.

The Fast and the Furious: A Case of Serotonin Syndrome Resulting From Snorting Multiple Medications

Poster Presenter: Manar Abdelmegeed, M.D., M.P.H.
Co-Authors: Abdullah Bin Mahfodh, M.D., Andrew Kerstein, D.O., Timothy D. Dellenbaugh, M.D.

SUMMARY:

We discuss a case of serotonin syndrome that presented with unorthodox route of administration, via inhalation. A 62 y/o female that presented to ED after she was found hallucinating with white powder around her nose. In the literature we find many cases that talk about serotonin syndrome via PO, IV and IM routes, but none discussing inhalation route. A route that is well known among addicts but not many healthcare professionals Serotonin syndrome is a critical medical emergency that has been around for decades.[1] It is well studied among most of medical specialties, however, due to it’s variable and nonspecific presentation many patients are often misdiagnosed, thus, many case goes undiagnosed and it’s difficult to determine the actual incidence of serotonin syndrome. In 2002, more than 7000 cases of Serotonin Syndrome were diagnosed and of those 93 cases were fatal.[2] The use of serotonergic medications continues to be on a rise, thereby, increasing incidence of serotonin syndrome. Serotonin syndrome results from the overactivation of central and peripheral serotonin receptors. Multiple psychiatric, pain, and even few antibiotics medications have an effect on serotonin metabolism and pharmacokinetics, leading to bigger chances of serotonin toxicity. Serotonin syndrome can occur with overdosing on serotonergic drugs as well as drug interactions of medications that have serotonergic properties. In conclusion, healthcare professionals should be oriented with this relatively new route that is widely known to addicts and that might even be misdiagnosed with overdosing. Additionally, it is important to understand the inhalation route and how it differs from other traditional routes (PO, IV, and IM) in pharmacokinetics, duration of symptoms, prognosis, and probably management. Thus, more studies focusing on inhalation route are needed.

Encephalitis’ ABCs: Aphasia, Behavioral Changes, and Cognitive Impairment as Long-Term Sequelae of Encephalitis

Poster Presenter: Sabeen Khaliq
Lead Author: Manar Abdelmegeed, M.D., M.P.H.
Co-Authors: Piyushkumar Jani, M.D., Bini Moorthy, M.D., Douglas Michael Burgess, M.D.

SUMMARY:

Encephalitis is an inflammation of brain parenchyma that affects people of all ages but occurs more commonly in children. Worldwide incidence ranges between 3.5 and 7.4 per 100,000 people per year. [1] The etiology of encephalitis includes infectious agents, autoimmune, and metabolic abnormalities. The most common cause is infection, particularly infections involving the herpes simplex virus (HSV). The clinical picture varies but can include fever, cognitive impairment, confusion, aphasia, and sometimes even death. [2] Rapid identification and intervention is crucial since any delay in treatment can impact morbidity and mortality. Our case report presents a previously high functioning male with no past psychiatric history who developed severe cognitive impairment with behavioral impairment following encephalitis. Most studies of viral encephalitis are focused on short-term outcomes but there is a paucity in research about long-term complications. This report highlights the long-term

sequelae of encephalitis especially aphasia and behavioral disturbances.

"Just a Pseudo Seizure?": A Case of Psychogenic Status Epilepticus: An Overlook on Complications of Non-Epileptic Seizures

Poster Presenter: Abdullah Bin Mahfodh, M.D.
Lead Author: Manar Abdelmegeed, M.D., M.P.H.
Co-Authors: Waquar Siddiqui, M.D., Nashaat Nessim Boutros, M.D., Maheshkumar Patel, M.D.

SUMMARY:

We describe a case of 30-year-old male with multiple Psychogenic nonepileptic seizure (PNES) episodes who progressed to psychogenic status epilepticus and was subsequently intubated. The diagnosis of PNES can be challenging and requires multidisciplinary workup, including video-electroencephalography studies that will exclude an epileptic seizure. Incidence rates of PNES in the general population are underdiagnosed. The prevalence of PNES ranges between 2 to 33 per 100,000 [1]. Among inpatient population evaluated for epilepsy; 25-40% are diagnosed with PNES. [2] Most cases discussing PNES either focus on differentiating it from epileptic seizure or management. However, data on complications and side effects of PNES is insufficient. PNES is a common, sensitive diagnosis, and might result in a medical emergency as occurred with our patient. This resulted in a concern regarding PNES prognosis and comorbidities, which will be discussed in our case report.

No. 57

Phantom Hallucinations: A Case of Isolated Tactile Hallucinations Associated With PTSD

Poster Presenter: Rohma Khan
Lead Author: Manar Abdelmegeed, M.D., M.P.H.
Co-Authors: Abdullah Bin Mahfodh, M.D., Waquar Siddiqui, M.D., Andrew Kerstein, D.O., Nashaat Nessim Boutros, M.D.

SUMMARY:

Hallucinations can be defined as wakeful sensory experiences of content that are not actually present. They can occur in any of the five sensory modalities. Auditory hallucinations are the most common in schizophrenic patients, followed by visual, tactile, olfactory, and gustatory hallucinations. Tactile hallucinations have been known to occur due to substance use but cases have been reported with stroke, or even medications like antidepressants, prescription stimulants, antihypertensives (propranolol), anti-Parkinson medications, and antiepileptics.[2][3][4]. In this case report, we review a 64-year-old African American male with a past medical history of schizophrenia, cocaine use (in remission), alcohol use (in remission), PTSD (following physical and sexual abuse), and a remote history of ventricular septal defect repair 20 years ago. Our patient reported having tactile hallucinations only limited to his lips, in the form of "kisses". He denied having any auditory or visual hallucinations. UDS on admission was negative for cocaine, amphetamines, PCP and blood alcohol level was also negative. At the time of this writing, patient has been hospitalized for 3 weeks, and the tactile hallucinations have been persistent despite monthly intramuscular injections of Paliperidone. He has been on Haloperidol and Risperidone in the past; both were not effective. In this case, we discuss isolated tactile hallucinations. There has been evidence that severe PTSD can be associated with tactile hallucinations, second only to auditory hallucinations in prevalence [1]. Tactile hallucinations are usually followed by an immediate twitch, so there may be a connection between these hallucinations and an excessive startle response (hypervigilance) seen in PTSD. Tactile hallucinations are a rare phenomenon and poorly studied; thus, further research is needed.

No. 58

Hypertensive Encephalopathy Following Electroconvulsive Therapy: A Rare but Serious Side Effect

Poster Presenter: Waquar Siddiqui, M.D.
Lead Author: Manar Abdelmegeed, M.D., M.P.H.
Co-Authors: Andrew Kerstein, D.O., Nashaat Nessim Boutros, M.D.

SUMMARY:

Electroconvulsive therapy (ECT) is a widely used treatment modality which uses a small electric current to induce a generalized cerebral seizure. It is considered one of the most effective and safest

treatments for severe depression. ECT is also indicated for patients with bipolar disorder, schizophrenia, schizoaffective disorder, catatonia, and neuroleptic malignant syndrome. Worldwide, it has been estimated that about one million patients receive ECT annually [1]. Side effects include anterograde and retrograde amnesia, aspiration pneumonia, fractures, dental and tongue injuries, headaches, and nausea. Mortality rate for ECT is estimated to be 1 per 10,000 patients or 1 per 80,000 treatments.[2] Rarely, there have been reports of patients suffering from uncontrolled hypertension post ECT sessions. We present a case of a 74-year-old Caucasian male with a past medical history of severe major depressive disorder, hypertension (HTN), and a remote history of viral encephalitis in 2004 who suffered from Hypertensive Encephalopathy post ECT. Patient did not have any previous history of seizures, traumatic brain injury (TBI), or family history of seizures. Computed tomography head done after ECT did not show any acute abnormalities. The ECT was administered through seizure induction with immediate postictal state. Later, patient woke up and blood pressure was normalized. In a few minutes, his blood pressure rose and SBP reached 220, he became unresponsive to painful stimuli, and had to be intubated subsequently. Video Electroencephalography (VEEG) on the same day showed generalized sowing of delta frequency with intervals of arousal suggesting deep, midline subcortical dysfunction, corresponding to encephalopathy. There have been only a few reported case of HTN encephalopathy post ECT. There is a need to increase awareness of this rare but potentially life threatening complication post ECT.

Tassy Say, Tassy Do: Eviction of Hallucinations

Poster Presenter: Natalie Andrea Seminario, M.D.

SUMMARY:

We present the case of a 39 year old African American woman with schizophrenia who reports that she is inhabited by a woman named “Tassy”. The patient has a long history of psychiatric admissions, previous placement at the state hospital, and poor treatment adherence, despite access to treatment and residential programs. On this admission, the patient was found screaming and crying on the side of the road and required assistance from police to deescalate and transport her to the psychiatric inpatient unit. The patient was withdrawn and only responded to internal stimuli, ignoring our initial attempts to approach and speak with her. After 2 days of witnessed adherence to psychotropic medications, the patient became more organized and divulged her delusion that she had a woman named “Tassy” living inside of her, speaking to her, and “advising her”. This patient reported that “Tassy” advised her that her family and the treatment team were against her and wanted her “to stink”; thus refusing communication with or help from family. The patient refused all medications, food and water from the treatment team for many days due to the delusion that ingestion of any kind would lead to her ‘stinking’, which she was afraid of and was her chief concern. Our initial non-pharmacological approach consisted of supportive therapy, listening to anything she wanted to share, and giving her the space she asked for and needed. While her paranoia created many initial barriers in our therapeutic relationship, it was clear that addressing it was the key to successful treatment. Her paranoia-built walls began to come down with medication, consistent supportive interviewing, and empathy in dealing with the patients needs. In the span of 1 week, the patient confided how involved “Tassy” was in all aspects of her decision making. “Tassy’s comments and constant presence was distressful for the patient which lead to her increased paranoia and resistance to treatment. Adjusting to her needs and slowly modifying behaviors resulted in positive outcomes for this patient. The etiology of schizophrenia is multifactorial, just as the symptomatology is and treatment of schizophrenia needs to be. Studies show in acutely psychotic patients, non-pharmacological approaches result in more

successful longterm outcomes when implemented in addition to pharmacological treatment. It is important to remember that while these patients are not experiencing reality, their experiences are real and distress; they not only require, but deserve attention. Patient care is improved when addressing all the stressors, even when they are not real to us.

Gabapentin Abuse: Prevalence and All-Cause or Drug-Related Medical Events With and Without Concomitant Opioid Abuse
Poster Presenter: Alyssa M. Peckham

SUMMARY:
Background: Despite international calls to make gabapentin a controlled substance, studies of gabapentin use/abuse patterns are limited to small/high-risk samples and adverse event reports. As such, gabapentin may be abused to potentiate opioid effects, though studies of medical events resulting from co-abused gabapentin/opioids are lacking. The primary objectives were to conduct a systematic assessment of the abuse potential/prevalence of gabapentin in a large sample, and assess patient harm, defined as use of inpatient hospital (IPH) or emergency department (ED) services, associated with overuse of gabapentin with or without concomitant overuse of opioids. Methods: Data were from the Truven Health MarketScan Commercial Claims and Encounters database, for the years 2013-2015. For prevalence assessment, patients with =2 claims for =1 abusable drugs and =12 months' continuous enrollment were sampled for Lorenz curve analysis. Prevalence analysis was limited to those with =120 days of therapy. Abuse potential was measured as Lorenz-1 (consumption of drug supply by top 1% of users) of 15%. Dose thresholds were morphine milligram equivalent (MME) standards for opioids, and maximum labeled doses in milligrams (mg) for other drugs. For medical events assessment, patients with =2 claims (billed encounters) and =120 days of treatment with gabapentin and/or opioids were included. Cohort identification was based on daily-dosage thresholds of 50 MME and 3,600 mg of gabapentin in a 12-month follow-up: (1) no overuse; (2) mild overuse (=2 claims or =2 calendar quarters over threshold); and (3) sustained overuse (=3 over-threshold calendar quarters). IPH and ED use were measured for 6 months after the first overuse date (cohorts 2 and 3) or a randomly assigned date (cohort 1). Logistic regression analyses controlled for pretreatment IPH/ED utilization, indication, addiction diagnosis, concomitant sedative/hypnotic use, and demographics. Results: Lorenz-1 values were 37% opioids, 19% gabapentin, 15% pregabalin, 14% alprazolam, and 13% zolpidem. The top 1% gabapentin users filled prescriptions for a mean (median) 11,274 (9,534) mg/day, =3 times the recommended maximum (3,600 mg). Of these, one-quarter used or diverted 12,822 mg/day. The top 1% opioid and pregabalin users filled prescriptions for a mean (median) 180 (127) MMEs and 2,474 (2,219) mg/day, respectively. Of patients using opioids+gabapentin simultaneously, 24% had =3 claims exceeding the dose threshold within 12 months. All-cause and drug-related IPH/ED utilization increased monotonically with degree of overuse, particularly of more than one medication. Sustained overuse of gabapentin multiplied odds of all-cause IPH by 1.366 [95% confidence interval (CI) 1.055, 1.769], drug-related IPH by 1.440 (95% CI 1.010, 2.053), and IPH/ED for altered mental status (e.g., euphoria, anxiety) by 1.864 (95% CI 1.324, 2.624). Sustained overuse of both medications quadrupled odds of all-cause IPH, drug-related IPH, a

Gabapentin Abuse: U.S. State-Level Mitigation

Policies and Need for Federal Pharmacovigilance
Poster Presenter: Alyssa M. Peckham

SUMMARY:
Background: Over the past decade, increased prescription supply has facilitated an epidemic of nonmedical use of controlled substances: predominantly opioids, as well as benzodiazepines, z-hypnotics, and stimulants. More recently, misuse of non-controlled medications, such as gabapentin, has been detected. Gabapentin misuse has been associated with drug-related harm and increased healthcare service utilization in several studies, including a recent large-sample analysis of commercially insured enrollees in the United States (U.S.) Although gabapentin is not considered a controlled substance by the U.S. Drug Enforcement Agency, states have the option to place more stringent criteria on its use, which may include Prescription Drug Monitoring Program (PDMP) reporting, reclassification of schedule status, or other restrictions on dispensing. Methods: To determine how individual states are responding to emerging evidence regarding gabapentin misuse, we investigated state-level policies using Web searches and follow-up telephone contacts. Web searches were conducted using the name of each state, coupled with the following search terms: PDMP, prescription monitoring program, gabapentin, controlled substance, schedule IV, schedule V, and schedule substance list. Telephone contacts were made to persons identified in the Web searches, and followed up with additional persons as needed. Results: States have begun to adopt legal and regulatory strategies to mitigate gabapentin abuse (Figure). Among the most stringent criteria are those adopted by Kentucky and Washington DC, which reclassified gabapentin to a Schedule-V controlled substance and mandated PDMP reporting of gabapentin, and Massachusetts which has classified gabapentin as Schedule-VI. Less stringent policies were adopted by Minnesota, Nebraska, North Dakota, Ohio, Virginia, West Virginia, and Wyoming, which implemented PDMP monitoring for gabapentin without reclassifying it as a controlled substance. Additional regulatory action may be forthcoming in Hawaii, Kansas, New Hampshire, New Jersey, and Pennsylvania, which have discussed gabapentin regulation at various levels but had not made any regulatory changes as of December 2017. Conclusion: Gabapentin represents an opportunistic prescription drug of abuse, given its modest cost and non-schedule status. Thus, it is critical that healthcare personnel become familiar with the prevalence of gabapentin abuse and misuse and the resulting potential for medical harm, adverse societal consequences, and economic burden. Absent a comprehensive federal policy, state-level restrictions may result in unintentional harms: (1) encouraging

No. 65
Motor and Vocal Tics as a Prodrome to Psychotic Illness: A Case Report
Poster Presenter: Adam Hubert Schindzielorz, M.D.

SUMMARY:
Schizophrenia is relatively common, occurring in 1% of the population and is often highly impairing to its sufferers. Thereby, it is of the utmost importance to be able to recognize and treat this disorder as early as possible. For the last several decades research has attempted to elucidate a variety of markers or predictive factors in order to aid in the identification of patients at high risk of developing a schizophrenia spectrum disorder. One such factor that has been studied are premorbid or prodromal movement disorders. Currently the literature has identified clear motor aberrations early in life, in some cases beginning in infancy; these have ranged from infantile hypotonicity to increased facial and upper body dyskinesias, as was seen in our patient. Many of the aforementioned changes are noted to develop very early on in the patient's course. We present a case of a 34-year-old male who developed a persistent motor and vocal tic disorder roughly 4 years prior to the development of schizophrenia with symptoms having continued throughout the course of his illness. The majority of the reviewed literature identifies movement disorders as beginning in adolescence with eventual development of a psychotic illness, however our case is unique it that demonstrates an individual with no known motor symptoms until adulthood with rapid development of psychotic symptoms thereafter.

No. 66

Folie à Deux in Identical Twins in an Immigrant Family and Review of Literature

Poster Presenter: Aditya Kumar Singh Pawar, M.D.
Co-Authors: Mitali Patnaik, M.D., Umair Akhtar

SUMMARY:
Folie a deux is a rare syndrome first described by Lasegue and Falret in 1877. It refers to sharing of delusional beliefs between two individuals either simultaneously or "induced" by one to the other. It is often seen in first degree relatives. Literature inconsistently suggests improvement with separation of individuals. Ms. A and Ms. B are 20 years old identical twin sisters who presented to the emergency room brought by family members on an involuntary commitment. Ms. A had a history of outpatient treatment for oppositional defiant disorder for past 6 years and had been non-adherent to treatment. Ms. B had no prior psychiatric history. For past few days both of them had been excessively aggressive towards family members, exhibiting homicidal threats and physically attacking them On mental status examination both appeared disheveled, had pressured speech, angry mood and affect, with persecutory delusion towards family members, accusing them of being from a different culture, and not understanding them. They believed family was trying to poison them and became agitated when this was challenged. Patients denied any hallucinations though family members reported that patients were seen talking to themselves. Insight and judgment were poor. They were examined separately by two psychiatrists in the emergency department and were admitted on different units. Risperidone 1mg PO was initiated which they refused to take. It was observed that Ms. A was more disorganized and paranoid. They partly improved with reduction in aggression and they stopped any homicidal ideation, though still exhibiting paranoia. They were discharged from the mental health court. Ms. B agreed to follow up outpatient, while Ms. A refused it, family members believed they could persuade her to follow-up. The above cases illustrate the presentation and fulfill the proposed criteria for folie a deux of close association between patients, of having identical delusional content, and that they should share and support each other's delusions. Since one of the patients had prior psychiatric history and appeared to be more disorganized it appears that she is the primary inducer. This is also supported by her continued refusal for treatment while the other patient agreed which may suggest development of partial insight. These cases also show how genetically related individuals may exhibit such shared vulnerability under psychosocial stress of being raised in an immigrant family with possible identity conflicts. Shared psychosis between twins has also been rarely described. Difficulty in separating vulnerable twins has been shown to even result in late onset psychosis. Separation of cases on the units may have served as a factor in initiating improvement of one patient's symptoms, but as the symptoms did not completely resolve over the short stay it can only be expected that they improve with outpatient therapy.

No. 67

It's Not Possible! A Case Report of a Rare Skin Disorder Coexisting With Schizophrenia

Poster Presenter: Alicia Tsai
Co-Author: Davin A. Agustines, D.O.

SUMMARY:
There is very little literature on the co-existence of albinism and schizophrenia. A PubMed search resulted with the last-known article published in 1989. Oculocutaneous albinism is a rare skin disorder, which occurs in 0.005% of the world population. At one point, it was hypothesized for schizophrenia to be impossible to occur with albinism (Greiner & Nicolson, 1965). We review past literature and theories about the coexistence of albinism and schizophrenia and also discuss what implications this case may have toward beginning to understand whether or not the two disorders may be genetically linked. Previous research has identified a schizophrenia-linked translocation breakpoint region on chromosome 11. Based on probable functional role and breakpoint proximity, four candidate genes for schizophrenia were identified-- one of which being tyrosinase, the lack of which causes albinism (Semple, Devon, Le Hellard, & Porteous, 2001). While the exact genetic cause of schizophrenia is still unknown, further research is encouraged to investigate the relationship between albinism and schizophrenia. We present a case report of a 25-year-old African-American male with oculocutaneous albinism type 2 (OCA2) and

schizophrenia. He was hospitalized after his mother discovered the existence of a BB that was lodged in his forehead from a failed suicide attempt in response to command auditory hallucinations. The BB was removed during his hospitalization, and he was psychiatrically stabilized on a combination of Risperdal, Lithium, and Lexapro. We will discuss this rare condition and its potential to be linked with schizophrenia.

No. 68
Advanced Paternal Age as Risk Factor for Schizophrenia in Offspring
Poster Presenter: Alina Babar
Co-Authors: Eric Michael Ewing, M.D., Pronoy Roy

SUMMARY:
M.S., a 20-year-old Hispanic man with a history of substance use and no major previous psychiatric history, was brought into the ED by his mother with the complaint of hearing voices and feeling paranoid for 1 week. The patient believed that strangers were watching him from outside his windows and that people could get into his mind. The patient had begun isolating himself from others and stated he had been feeling increasingly unsafe. The patient's mother stated that M.S. had been hiding a baseball bat behind his door for protection. M.S. denied regularly using marijuana or other substances. He denied any family history of Schizophrenia or other psychiatric conditions, and he denied previous similar episodes. However, the patient revealed that he was stressed for the past year because his father had passed away at the age of 93. The patient's father was 73-years-old when he was born, and at the age of 20-years-old, the patient showed signs of Schizophrenia. He was admitted to the inpatient unit for stabilization. The patient was initially isolative and said he felt depressed, but with medication and appropriate titration, his symptoms began to improve. After observation and management of the patient's symptoms for several months, he was officially diagnosed with Schizophrenia. Although the exact etiology of Schizophrenia spectrum disorder is not completely understood, there is a strong genetic predisposition associated with this condition. With this case, we hope to look at advanced paternal age as a risk factor for Schizophrenia. This association can be explained by examining male germ cell development and de novo mutations. The effects of advanced paternal age on the health outcomes for offspring may become more evident over time as parenthood is being delayed in many societies. Further analysis of advanced paternal age as a risk factor for Schizophrenia could provide us with the ability to mark specific genes as candidates for this disorder.

No. 69
Treatment Considerations in First-Episode Psychosis
Poster Presenter: Anand Satiani, M.D., M.B.A.
Co-Author: Walter Stearns, M.D.

SUMMARY:
Mr. Z is a 20-year-old male with no prior treatment history who, over the course of 3 months, developed a marked delusional system revolving around the Trump Administration and apocalyptic-type delusions. After attempting to convince his family to move to Argentina for their safety, he was transported to the ER and admitted for psychiatric stabilization. Mr. Z was diagnosed with schizophreniform disorder, treated with risperidone titrated up to 6 mg in a matter of two weeks, and discharged. He demonstrated fair improvement in his psychosis but developed notable apathy and dysphoria, both of which he had never experienced previously, as well as prominent sexual side effects. He was subsequently readmitted two weeks later for suicidal thoughts, which had had never experienced previously. Escitalopram was added and risperidone was cross-titrated to aripiprazole given side effects. These changes led to a resolution of his dysphoria, apathy, and sexual side effects, and his psychosis continued to improve with more time on antipsychotic medication. This case highlights the need to be mindful about dosing and side effects in first episode psychosis patients as they generally require lower dosing and to be given more time to respond, which they do at higher rates. In addition, this patient population is acutely sensitive to the dopamine blocking effect of antipsychotics with regards to side effects. This case also highlights the need to seriously consider use of a partial D2 agonist at the initial stage of treatment, which frequently is bypassed out of concern for decreased efficacy and slower response time.

No. 70

Complete Bilateral Self-Enucleation: A Case Report

Poster Presenter: Arindam Chakrabarty, M.D.
Co-Authors: Mariyah Z. Hussain, M.B.B.S., Ashima Datey Chakrabarty, M.D., Eric Black

SUMMARY:

Ms. X, a 25-year-old Caucasian female with a past history of schizophrenia, an inmate at a correctional facility for the past year presented to the ER with bilateral self-enucleation. Per reports she was usually reclusive to her room and hardly talked to anyone at the facility until an escape attempt she made 5 days prior to presentation, completely against her usual behavior. On the night prior to admission, a guard found her staring out of her cell calmly with missing eyeballs. She had gouged out both her eyeballs with her bare hands, and was brought to the ER. The eye-globes were brought on ice in a bag to the ER and were intact with optic nerve measuring 45mm. She had her eyes bandaged and ophthalmology opined that vision could not be saved and planned for cosmetic surgery. At presentation in the ER she rated her pain as mild despite the severity of the trauma. The patient had been incarcerated for stabbing her son and had been under psychiatric treatment in the facility. At the time of psychiatric evaluation, she was laying shackled to the bed. She was in 4-point restraints as she kept attempting to scratch at the bandages on her eyes. Earlier she had tried to rip out her intravenous drip when she was in 2-point restraints. She was extremely guarded and gave very few responses. The responses she gave were suggestive of a religious theme with her saying she was in 'Hell' and then later stating she was in 'Heaven' in response to orientation questions. She barely spoke and seemed internally preoccupied. She did not seem to realize the consequences of her action, as she kept wondering why she could not see. The patient continued to attempt self-harm, despite being in restraints, by trying to bite off her tongue. A mouth guard had to be placed to prevent further injury and psychiatric evaluation was completed over the course of her hospital stay. She was started on olanzapine while she was treated by the ophthalmology team in the hospital. The patient was later transferred to a forensic psychiatric facility for long-term treatment with antipsychotic medications. Self-inflicted eye injuries are rare and have been associated with a variety of psychiatric and organic disorders. There are multiple references to enucleation in mythology with the story of Oedipus being one of the most commonly known. Numerous psychodynamic theories exist to explain self-inflicted eye injuries as a form of self-mutilation. Biochemical theories have implicated serotonergic, dopaminergic and opioid pain pathways. Treatment requires close cooperation between psychiatrists and ophthalmologists as well as physicians, neurologists, and neurosurgeons when necessary. Management also often includes collaboration with forensic teams as these injuries are often seen in the prison setting. In this poster, we discuss the different suggested theories, the clinical characteristics and the challenges faced in the management of these patients.

No. 71

Anosognosia in Schizophrenia: Neurobiological Correlates,Treatment Considerations and Prognosis

Poster Presenter: Ashaki Martin, M.D.
Co-Authors: Luisa S. Gonzalez, M.D., Modupe Ebunoluwa James, M.D., Abbas Naqvi, Katya Frischer, M.D.

SUMMARY:

Anosognosia is the denial of illness or failure to appreciate one's deficits. Anosognosia is a common manifestation in Schizophrenia with a prevalence of approximately 60%. Numerous individuals diagnosed with Schizophrenia, lack awareness of and fail to recognize the signs, symptoms and consequences of their illness. This level of unawareness poses significant challenges to clinicians, as it is linked to poorer adherence to treatment, frequent hospitalizations, increased risk of relapse and psycho-social difficulties. Currently, limited data exists regarding the treatment of anosognosia as a means of improving outcomes in Schizophrenia. In this poster, we discuss the barriers to effective treatment of a 49 yr old African American female with Chronic Schizophrenia, noncompliance with psychotropic medications, more than twenty (20) previous psychiatric hospitalizations who presents at baseline with severe lack of insight into her condition. This poster will also explore the

underlying neurological understanding of anosognosia in medical and psychiatric illness. In addition, it aims to highlight the need to use specific modalities of treatment for insight enhancement, as an integral factor in the management of patients with Schizophrenia towards positively impacting their overall quality of life.,

No. 72

Paranoia on My Mind: Exploring the Many Meanings of Paranoia in Clinical and Forensic Decision-Making

Poster Presenter: Rami Abukamil, M.D.
Co-Author: Christopher Paul Marett, M.D., M.P.H.

SUMMARY:
The many colloquial and scientific conceptualizations of paranoia can lead to confusion regarding its meaning. This can adversely affect the accuracy of clinical and legal decisions based on mental state. Accurate diagnosis and appropriate education about the context of paranoia is critical to guide treatment and to avoid pigeonholing individuals based on the label of paranoia alone. When miscommunication about this term occurs, patients may receive improper care, unnecessary stigma, and legal entities may make erroneous decisions. This poster presents three case examples highlighting the importance of distinguishing the origins and characteristics of paranoia and how it can affect subsequent medical and legal decisions. Case 1 examines the treatment of Mr. A, a man who was afraid to leave his apartment because he was "worried that something was going to happen." His treatment team explored a label of "paranoid" to this thought and behavior pattern, and it affected the course of his treatment. Case 2 describes an evaluation for civil commitment of a "paranoid" patient who had served in the military and had great mistrust for the government. Case 3 explores "paranoid" thoughts in a hospitalized patient who needed surgery. While performing a capacity assessment, the psychiatry consult team explored Mr. C's attitudes about why he "did not want them doing experiments on me" and why he believed "they are trying to kill me!" Through these case examples, we examine the meaning and context of paranoia in different situations. Our poster will also propose ways to classify paranoia appropriately based on dimensions of neurobiology, neurocognition, psychodynamics, and nosology. This classification scheme serves to elucidate clinical and forensic decision making.

No. 73

A Probable Case of Cycloid Psychosis

Poster Presenter: Bruce D. Fox, M.D.
Co-Author: Sarayu Vasan, M.D., M.P.H.

SUMMARY:
Introduction: Karl Kleist is who coined the term "cycloid psychosis" in 1926, referring to cases of acute onset psychosis with recovery period between recurrences. The cases did not meet criteria for schizophrenia, bipolar disorder or depressive disorder. The course of the disorder is episodic as in bipolar disorder however; the acute symptoms are psychotic in nature, as in schizophrenia (Yadav, 2010). Cycloid psychosis, as described by Leonhard, is defined as endogenous psychosis which is neither a mood disorder nor schizophrenia. He further categorized the diagnosis into three classes-motility psychosis, confusion psychosis, and anxiety-blissfulness psychosis (Leonhard, 1961). In 1982, Brockington and Perris published the diagnostic guidelines for cycloid psychosis and considered the diagnosis as a separate entity reporting the condition did not equal schizoaffective disorder despite the high prevalence of mood symptoms (Perris et al., 1982). Case: The authors present a case study of cycloid psychosis in a 50-year-old Hispanic female with minimal functional impairment between her episodes. This case report intends to value the concept of cycloid psychosis emphasizing its importance as it is often neglected in literature and in clinical practice. Discussion and Conclusion: With the onset of the operational diagnostic criteria, the nosological validity of cycloid psychosis was in question due to the similarities present between previously classified mental disorders. Speculations arose challenging whether cycloid psychosis is its own entity or on a spectrum between Schizophrenia and Bipolar Disorder. Further, ICD - 10 recognizes "acute and transient psychotic disorder" and DSM - V "schizophreniform disorder" and "brief psychotic disorder", both accounting for acute psychotic syndromes currently defined in the accepted classification systems, making the differentiation of

cycloid psychosis a concern. However cycloid psychosis maintains distinct differences, which supports the theory that this should be categorized as its own disorder. Despite the accumulated evidence suggesting that cycloid psychosis is a separate class, the DSM V fails to mention the disorder as a separate diagnostic criterion. The case report demonstrates the significance of the diagnosis given its distinctive prognosis and management when compared to other psychoses. This disorder is not well described and is worthy of additional research and scientific attention.

No. 74

Cabergoline Associated With First-Episode, Treatment-Refractory, Schizophrenia-Like Psychosis in a Woman With Hyperprolactinemia

Poster Presenter: Christopher Richard Green, M.D.

SUMMARY:

Cabergoline is a primarily D2 receptor agonist that can cross the blood brain barrier and has been associated with rapidly resolving psychosis in a few case reports. This is a report on a case of a 46-year-old woman, employed as an administrative assistant without any significant prior psychiatric history, with early menopause, who developed a treatment refractory schizophrenia-like syndrome. She had been treated for hyperprolactinemia, likely due to a microprolactinoma, for 9 months prior to admission. She presented with paranoid delusions and auditory hallucinations for 2 months, and was found to have a disorganized thought process and blunted affect. Extensive workup, including bloodwork, lumbar puncture, video EEG, and brain MRI did not reveal another medical cause of her psychosis. She failed to respond to several antipsychotic regimens, or 7 treatments of ECT, over 14 weeks of inpatient treatment. She has been referred to a state psychiatric hospital. This is the first case report of cabergoline associated psychosis that did not rapidly resolve, either on its own or with brief treatment. Her course may have been affected by especially high risk factors. Her brother had a history of schizophrenia and she was going through early menopause, representing a low estrogen state, which epidemiologically has been associated with a second wave of schizophrenia development. In conclusion, there may be irreversible psychiatric reactions to cabergoline. It may be useful to consider individual risk factors when starting dopamine receptor modifying medications and to further investigate dopamine agonists that do not cross the blood brain barrier.

No. 75

Psychostimulant Administration for Cognitive Functioning in Schizophrenia: Two Cases With Positive Outcomes

Poster Presenter: Christopher Cho, M.D.
Lead Author: Rimal B. Bera, M.D.
Co-Author: Joshua Daniel Goh, M.D.

SUMMARY:

Schizophrenia is a highly heterogeneous disorder with a relatively constant clinical phenotype involving cognitive deficits and positive and negative symptoms. While pharmacological developments have shown notable effects on positive symptoms, antipsychotic medications have demonstrated modest or little to no significant effect on cognitive deficits or negative symptoms associated with schizophrenia. As such, these debilitating features of schizophrenia are with limited treatment options. Earlier studies have suggested that central nervous system stimulant medications may have a small effect on improving negative symptoms and cognitive deficits. We will be discussing two cases of chronic schizophrenia, both male and in their 60s and with cognitive impairments, who were started on stimulant medications in conjunction with their antipsychotic medications. As these two patient reside in a residential treatment center, we have been able to closely observe improvements in their cognition and ability to participate in activities and ability to complete tasks. In addition, Cognitive testing (CPT and WAIS-VI) performed before and after initiation of the stimulant reveal objective improvements in patients' cognition and ability to complete the tests. This could add additional evidence that adding a psychostimulant to a schizophrenia medication regimen may be of possible benefit.

No. 76

Is It Delirium, Myxedema Madness, or Hallucinogen Intoxication? Medical and Psychiatric Complications in Treating Persistent Psychosis

Poster Presenter: Dave Peyok, D.O.
Co-Author: Kimberlee V. Wilson, D.O.

SUMMARY:
Ms. D. is a 26-year-old single, Caucasian female with known Schizophrenia, hypothyroidism and polysubstance abuse, (alcohol, cannabis, methamphetamine, benzodiazepine, nicotine) readmitted to inpatient psychiatry for acute psychosis and non-compliance with court-ordered psychiatric treatment. The patient was escorted by law enforcement as a danger to others after an alleged assault at home toward family members with weapons. She had failed to participate with her ACT team and had not appeared for medication appointments nor the REMS-required laboratory testing for clozapine therapy. She presented floridly disorganized with loosely associated thought, extremely aggressive and impulsive behavior but often euphoric in mood and frequent gesturing, posturing and verbally responding to internal stimuli. Her appearance was bizarre; with an unevenly shaved head, she had attempted to shave herself, and inappropriately worn clothing and footwear. Initially she was unable to perform complete ADLs, would not shower for weeks and had frequent urinary/fecal incontinence. Due to her impaired insight and judgment, and non-compliance with blood draws, her treatment began with both immediate acting intramuscular injections and oral antipsychotics other than clozapine, with a goal to stabilize on a long acting injectable formulation. Multiple second-generation antipsychotics were minimally effective, and due to poor response, it appeared her baseline functioning was permanently declined. Discussions for discharge planning began with the focus on long-term residential placement. Throughout this admission, the patient continued refusal of all laboratory testing, as it was suspected she feared illegal substances might be found. During the second month of her admission collateral information was obtained from family that the patient had consumed an entire sheet of Lysergic acid diethylamide (100 hits) at one time. Because her behavior was consistent with hallucinogen intoxication, Pimavanserin was considered as treatment to combat the serotonin overload associated with LSD psychosis. Prior to insurance authorization of Pimavanserin, Ms. D. consented to laboratory studies. She was found to have urosepsis and hypothyroidism. After treatment with antibiotics and levothyroxine her delirious behaviors waned. As her insight and cooperation improved, she was able to resume treatment with clozapine. Over the course of clozapine titration the patient responded successfully again and was allowed to be discharged back to her family home. In this poster, we discuss the importance of differentiating psychotic symptom etiology through obtaining complete, accurate, and reliable information on every patient, and to include substance use and medical histories in an objective and non-judgmental manner.

No. 77
The Brain Drain: A Review of Mitochondrial Changes Associated With Neural Dysfunction in Schizophrenia
Poster Presenter: David Arthur Aguilar, M.D.

SUMMARY:
The Brain Drain – A Review of Mitochondrial Changes Associated with Neural Dysfunction in Schizophrenia David Arthur-Aguilar, MD1, Eduardo J Rodriguez-Perez, MD1, Brian Ladds, MD1 1Lincoln Medical Center, Bronx, New York, United States Background Schizophrenia (SZ) is associated with abnormal mitochondria in postmortem and stem-cell studies. Mitochondrial diseases often present with neuropsychiatric symptoms, leading authors to suggest a mitochondrial inheritance pattern of SZ. The molecular link between mitochondria and SZ pathology has been investigated through the Disrupted-in-Schizophrenia-1 (DISC-1) gene and its protein products. Here we review the relevance of DISC-1 to mitochondrial function, and its possible connections to SZ pathology. Methods We conducted a PubMed search for review articles and original research with titles containing combinations of mitochondria AND schizophrenia OR DISC-1. 101 articles were identified. Exclusion criteria (e.g. Non-English, >10 years old) resulted in the 20 articles reviewed here. Discussion DISC-1 mutation and altered gene products impact mitochondrial functions. Specifically, DISC-1 alterations result in impaired mitochondrial trafficking, fusion, fission, and altered interface with endoplasmic reticulum. This leads to altered bioenergetics, calcium homeostasis, and management of oxidative stress.

These impaired cellular processes can lead to abnormal neuronal development and death, which has been implicated in SZ. Conclusions Dysfunctional molecular pathways are involved in the disease process of SZ. DISC-1 shines a light on the multiple ways that mitochondrial dysfunction could contribute to SZ, and the potential role of mitochondrial inheritance in SZ.

No. 78

A Allele in 196G/a of the BDNF Gene Polymorphisms May Predict Suicidal Behavior in Schizophrenia Patients

Poster Presenter: Eun Jeong Kim
Co-Author: Yong-Ku Kim

SUMMARY:
Background: Brain-derived neurotrophic factor (BDNF), mediates neuronal survival, differentiation, synaptic plasticity. Its relation with etiology of schizophrenia has been studied most recently. Because BDNF modulates dopaminergic and serotonergic pathways and Hypothalamic-pituitary-adrenal (HPA) axis regulation, it has been suggested that it has possible neurobiologic impact on etiology of schizophrenia. We hypothesized that the specific allele or the genotype such as three SNPs, 196G/A (rs6265), 11757G/C(rs16917204), and 270C/T(rs56164415) is associated with schizophrenia. Furthermore, discovering any relationship of specific clinical variables with specific allele or genotype distribution will help manage the patients. We also examined different alleles or genotypes and their impacts on clinical variables, including the severity of symptoms, the previous history of suicide attempts, the number of admissions or duration of disease. Methods: 241 normal controls and 157 schizophrenia patients are included as participants. To evaluate severity of patients' symptoms, Positive And Negative Syndrome Scale(PANSS), Brief Psychiatric Rating Scale(BPRS), and Korean version of the Calgary Depression Scale for Schizophrenia (K-CDSS) were assessed. Demographic data and past personal history of patients, including family history of psychiatric disorders and previous suicide attempts, were collected. The differences in allele or genotype distribution for the patients and normal controls were analyzed by using ?2- test. We also analyzed differences in demographic or clinical variables depending on genotype or allele differences in each SNPs. We analyzed the data using independent t-test and ANOVA to compare clinical variables. Results: We found no significant difference in genotype or allele distributions of three studied SNPs between the patient group and the control group. For clinical variables, PANSS, BPRS, and K-CDSS of each allele or genotype showed no difference among groups. However, history of suicide attempt was relatively higher in patients with genotype A/A, G/A compared to patients with genotype G/G for 196G/A. Conclusions: Our results suggest no specific allele or genotype can predict the susceptibility of schizophrenia in studied SNPs. Still, our results suggest that it is possible to use BDNF gene allele and genotype as a predictor for suicide attempt in schizophrenia patients. The rate of suicide attempt in schizophrenia patients is as high as that in major mood disorders patients. Regarding this, our results can help manage the patient with schizophrenia in order to reduce mortality. We can also assume that the BDNF gene polymorphism is related with specific symptom entities rather than disease itself. Further research with larger population and various ethnicity subjects is needed to confirm our current study result.

No. 79

Compulsory Outpatient Treatment: Who Are the Patients Who Are Transitioned to Voluntary Treatment?

Poster Presenter: João Oliveira
Co-Authors: Gonçalo Sobreira, Zita Gameiro, Sofia Brissos

SUMMARY:
Objective: Data regarding compulsory outpatient treatment (COT) effectiveness remains inconsistent. We describe and compare the characteristics of patients followed in a specialized COT consultation who were transitioned to voluntary regimen, and of those who were maintained on that regimen on the last observation. Methods: Naturalistic, longitudinal analysis, of 30 patients divided in two groups: those whom in the last evaluation transitioned to voluntary regimen (n=7), and those maintained in COT (n=23), evaluated with the Positive and Negative Syndrome Scale (PANSS), Personal and

Social Performance Scale (PSP), Berrios-Markova and Scale to Assess Unawareness in Mental Disorder (SUMD), and Trails A and B. Results: Patients transitioned to voluntary regimen were followed for less time, i.e. a mean of 6 vs. 9 months, and improved significantly on all PANSS subscales, as compared to patients maintained on COT who improved significantly on positive symptoms only. Improvement in personal and social functioning and in objective insight was more marked in patients transitioned to voluntary regimen. Regarding cognitive performance, only patients transitioned to voluntary regimen showed significant improvements in a measure of processing speed (Trail-A). Conclusions: A sub-set of patients seems to improve while on COT in symptoms, personal and social functioning, objective insight, and cognition, and can be then transitioned to voluntary regimen. More studies are needed to understand the possible benefits of psychiatric COT.

No. 80

Repetitive Transient Psychotic Episodes Associated With Tonsillitis

Poster Presenter: João Oliveira
Co-Authors: Cátia Alves Moreira, Gonçalo Sobreira, Sofia Brissos

SUMMARY:
INTRODUCTION There is increasing interest in the role of the immune system in psychotic disorders. Upper respiratory infections, specifically, have been associated with mental illness. Whether they represent a risk factor for mental disorder or the other way around is not clear, and the possible mechanisms for that association are still unknown. We present the case of a patient with three acute transient psychotic episodes (ICD-10 F23), each following an episode of tonsillitis, and discuss the plausibility of such association with a brief review of literature. METHODS Case report and narrative literature review of the PubMed database. CASE REPORT A 47-year-old male patient was admitted to a psychiatric inpatient unit following a sudden episode of agitation, persecutory delusions and visual hallucinations with less than 24h evolution. There were no significant changes in mood, attention and consciousness, or negative symptoms. He presented slightly elevated white blood cell count and C Reactive Protein (CRP) which were attributed to agitation. Toxic screening was negative and the head CT-scan was unremarkable. He began treatment with antipsychotics (APs), and attained remission/resolution in 4 days; the white blood cell count and CRP increased during the first days of inpatient care, despite the patient being no longer agitated, but normalized shortly thereafter. On reviewing the patient's clinical file, we found that he had had two previous similar episodes, both starting few hours after the diagnosis of tonsillitis and completely clearing a few days after antibiotic and AP initiation. The patient had been completely asymptomatic for over ten years without APs. He was discharged and AP treatment was slowly withdrawn after 6 months; two years later, the patient remained symptom free. DISCUSSION The immune system may be involved in psychotic disorders in several ways. Microglia, specifically, seem to be partly responsible for pathological pruning and the negative and cognitive symptoms of schizophrenia. However, the association of inflammation with positive symptoms is less clear and may not be related to microglial profile but to a cross-reactive auto-immune response. Regarding upper respiratory tract infections, we found only four cases in the literature of a possible causal link with psychotic symptoms (unrelated to Sydenham chorea, PANDAS or adverse effects of medication). No possible cross-reaction target has yet been identified. CONCLUSION Although the role of the immune system in negative and cognitive symptoms of schizophrenia is increasingly recognized, there are reports to build a case for the possibility of a causal connection between respiratory tract infections and acute psychosis in vulnerable patients which warrants further research efforts to identify which patients may not require chronic treatment with AP.

No. 81

Dissociation in PTSD and in the Courts: A Literature Review

Poster Presenter: Alyssa Beda
Co-Author: Eindra Khin Khin, M.D.

SUMMARY:
Dissociation is a polarizing clinical phenomenon among psychiatrists. The phenomenon has been described in Dissociative Identity Disorder (DID),

Post-Traumatic Syndrome Disorder (PTSD), dissociative amnesia, and other trauma-related experiences, yet much of the existing literature and legal basis of a dissociation criminal defense surrounds that of DID. This study will examine the manifestation of dissociation in various clinical contexts and how these are viewed in the eyes of the law. Another complicating matter to address is the distinguishing points between the dissociation phenomenon, unconsciousness, and alcohol induced "blackouts," all of which have different legal standings. The literature review demonstrates that amnesia and dissociation have been associated with violent crimes propagated by a wide variety of people, including veterans, college students, psychiatric patients, and domestic violence perpetrators. Acts of violence during a dissociative state have been associated with a lack of planning and premeditation, increased emotional states, emotional ties to the victim, and alcohol use. However, alcoholic blackouts and substance do not qualify in the criteria for dissociative disorders. There is considerable controversy concerning amnesia for offenses, along with the basis of amnesia itself. In States vs. Stevens, it was determined that amnesia is not a bar to prosecution of an otherwise competent defendant. On the other hand, even before PTSD was first described as an official diagnosis in DSM-III, traumatic stress syndromes were successfully offered as bases for criminal defenses. Various PTSD phenomena presented in courts as criminal defenses included dissociative flashbacks, hyperarousal symptoms, and survivor's guilt; however, dissociate flashbacks may be the most plausible defense. The diagnosis of PTSD has served in insanity defenses, unconsciousness defenses, and even as self-defense. Unlike other dissociative disorders, PTSD has been consistently shown to meet the Daubert Standard, thus deemed reliable and admissible in court. The proposed characteristics of authentic PTSD dissociation observed with criminal acts include a sense of a motive or explanation for the crime, lack of premeditation, similarities between the circumstances of the crime and the trauma causing PTSD, a random or fortuitous victim, and no criminal history. The aim in this analysis is to shine a light on clinical nuances involved in the dissociative phenomenon, and how they can take on varying paths within legal matters. In this process, important legal concepts such as Daubert Standard and M'Naghten Rule are reviewed. Based on our literature review, of all the dissociative phenomena recorded in the DSM and applied to a court of law, PTSD with dissociation appears to most likely to hold up as a criminal defense.

Quadruple Hazards of Methamphetamine Psychosis, Delusional Identification Syndrome, Violence, and Competency to Stand Trial: A Forensic Case Report

Poster Presenter: Andrew Sadek
Co-Author: Simon S. Chiu, M.D., Ph.D.

SUMMARY:

RB, a 31-year single male of Caucasian decent of no fixed address, presented to the emergency department of a urban hospital with visual and auditory hallucinations. He was highly agitated and panicky in describing his visual experiences: he was "seeing many family members" whom he recognized from his familiar "dope houses" in the downtown area. He complained of excruciating pain related to his training for the marathon event in order to escape from many people." He was somewhat confused and bewildered in his report of "seeing his family members in the emergency room." He has had repeated emergency visits related directed to his substances of abuse. He preferred to snort or to inject Crystal Meth: methamphetamine (Meth), despite the medical complications of rhadomyolysis and hepatitis C. His preferred substance of abuse switched from opiates: hydromorphone to Meth about 1 year ago. He switched from his heavy opiate use to Meth while he received methadone maintenance. He endorsed grandiose and paranoid delusions a involving his fear of being poisoned by arsenic. He claimed he worked for the federal agents. During his hospitalizations, he became highly belligerent and hostile accusing staff of conspiring against him. He was totally convinced that his parents came from" two different Asian countries, and that he "came through the wall of China." He held that he had undisclosed connections with the late Kung Fu master in Hong Kong. He was observed to be practicing Kung Fu rituals to defend himself against evil spirits when he was actively

hallucinating. His forensic history included multiple offenses of assaults causing bodily harm, uttering threats and repeated breach of judicial release. He was committed to the forensic psychiatric hospital for his recent episode when he grabbed a female innocent bystander screaming and yelling. He was found to be incompetent to stand trial for his alleged offenses of "utter threats and assault causing body harm." Competency to stand trial was finally restored after a 4-month period of pharmacotherapy involving both depot and oral atypical antipsychotics combined with mood stabilizers/antiepileptic agents. The case report highlights for the first time delusional identification syndrome: variants of Fragoli syndrome and inter-metamorphosis syndrome i as core symptoms of Meth-psychosis and schizophrenia. Recent studies show both schizophrenia and methamphetamine-induced persisting psychosis share similar gene risk genes and neurobiological lesions in the serotonin and dopamine systems. We report for the first time Meth psychosis and neurocognitive impairment sustains violence and identify delusional syndrome. The marginal and slow response to antipsychotics leading to his reversible incompetent to stand trial, can be explained by the neurotoxic effect of Meth. The case report illustrates the controversies regarding the actus reus and mens rea in Meth psychosis and criminality.

No. 83

Risk Assessments After Incidents: How Good Are We?

Poster Presenter: Donna Arya

SUMMARY:

RISK ASSESSMENTS AFTER INCIDENTS: HOW GOOD ARE WE? Dr Jose Romero-Urcelay (Medical Director), West London Mental Health NHS Trust. Dr Ainslie Boyle (Forensic Psychiatry ST4), West London Mental Health NHS Trust. Dr Donna Arya (Forensic Psychiatry ST5), West London Mental Health NHS Trust. Aims: An audit/quality improvement project designed to improve the documentation around risk following serious incidents. This project also strived to improve the timing of documentation following serious incidents. Analysis of the updating of risk assessment tools and the timings of this in relation to serious incidents on the forensic wards. We determined current practice and subsequently made recommendations and suggestions regarding documentation of this. We determined whether risks have been appropriately incorporated into care plans. Method: A random selection of serious incidents on the Forensic Wards (medium and low security) of St Bernard's Hospital was provided to us. A data collection tool was used to obtain information from the risk summaries, HCR-20 and progress notes sections on RiO (electronic records) of inpatients. The data was analysed using Microsoft Excel. Results: 43 incidents were included. 6 incidents were excluded due to the incident not meeting the criteria and one incident was excluded due to data not being made available to us. 60% of incidents were not included in the risk summary of the patient involved. The time taken to update the risk summary ranged from 1-108 days following an incident. No incidents were included on the risk summary on the same day. 72% HCR-20s were not updated following incidents. 21% of care plans did not include the risk behaviour demonstrated during the incident. Conclusions: Risk summaries and HCR-20s were not updated for the majority of incidents looked at. When they were updated they were not done in a timely fashion following an incident for the majority of the time. The majority of patients had a care plan in place at the time of the incident and the majority did include the risk behaviour relevant to the incident. The clinical risk policy section does not explicitly state the time frame in which risk assessments should be updated following incidents. Recommendations will be made about this.

No. 84

Length of Stay in Jail and the Risk of Self-Harm Among Individuals on the Mental Health Service in the New York City Jail System

Poster Presenter: Emily Nash
Co-Authors: Connor Bell, M.P.H., Semmie Kim, M.P.H., Elizabeth B. Ford, M.D.

SUMMARY:

Background: Self-harm poses significant health risks in correctional settings. While psychiatric illness may put individuals at risk for self-harm, the jail environment may also contribute to this risk. Current literature has shown inconclusive findings on the relationship between length of stay (LOS) in

jails and prisons and the risk of self-injury and suicidal behavior. This study seeks to better understand to what extent the risk of self-harm in a jail setting may be influenced by individual factors versus exposure time to jail. Methods: We conducted a retrospective chart review of the electronic health record of the NYC jail population and identified all documented acts of self-harm. We collected data for 58,890 incarcerations of individuals on the mental health service who were admitted to jail between May 1, 2011 and November 29, 2014. We examined the effects of age, race, sex, criminal top charge severity, serious mental illness designation (SMI), and total LOS in jail on self-harm using univariate and multiple logistic regression. Separate logistic regression models were conducted using the solitary confinement variable, since this housing data was only available for those in jail on or after October 1, 2013. Results: SMI, longer LOS, and younger age significantly predicted higher odds of self-harm after controlling for age, sex, race, LOS, SMI, top charge severity, and solitary confinement. The odds of self-harm increased with increasing LOS in a positive dose-dependent relationship. Compared to those in jail for 1 week or less, the odds of self-harm were significantly higher for those in jail for 4-6 months (AOR 11.84, [99% CI 7.19 – 19.49], $p < 0.001$), higher for those in jail for 6-8 months (AOR 13.63, [8.28 – 22.44), $p < 0.001$) and highest for those in jail longer than 8 months (AOR 24.19, [14.88 – 39.32], $p < 0.001$). Those with SMI had significantly higher odds of self-harm (AOR 1.84, [1.59 – 2.13], $p < 0.001$) versus those without an SMI designation. Age and self-harm were significantly negatively associated in a dose-dependent relationship. Compared with those ages 51 and older, the odds of self-harm were significantly higher for individuals ages 22-30 (AOR 7.21, [4.80 – 10.82], $p < 0.001$), even higher for ages 18-21 (AOR 12.42, [8.20 – 18.82], $p < 0.001$), and highest for ages 16-17 (AOR 27.28, [17.69 – 42.07], $p < 0.001$). Conclusion: While SMI status contributes to the risk of self-harm, longer LOS in jail and young age stand out as strong predictors of self-harm in this population of individuals on the mental health service in the NYC jail system. These data add to the literature documenting significant health risks associated with prolonged stays in jail and emphasize particularly the increased risk of self-harm for those with mental health concerns.

No. 85

Behind the Screen: Which Child Pornographers Should We Watch Closely?

Poster Presenter: Gael Fournis
Co-Authors: Jouin Raphaelle, Nidal Nabhan Abou

SUMMARY:

Background: Child pornography is a form of sexual exploitation of children. The advent of new information and communication technologies, especially the Internet, has encouraged wider dissemination. Understanding the phenomenon of child pornography is complex, because it is sometimes a matter of deviance without leading to actual abuse. Thus, the main issue faced by law enforcement agencies is the level of danger posed by consumers of this type of media. Essentially, magistrates must recognize the risk of sexual assault associated with this behavior. Forensic psychiatrists have to give psycho-criminological information to explain the offense and to allow the prosecutor to make appropriate decisions. **Objective:** This study aims to determine the psychopathological and criminological difference between child pornographers and dual offenders who acted out, by analyzing forensic assessments in child pornography cases, and thus identify risk factors for sexual assault within this specific population. **Methods:** We are analyzing the data of 60 forensic reports. We had previously identified items that are related to sexual offenders, and widely criminal risk factors, reported in the literature. Applying this grid of reading, we expect identify items that would stand out in dual offenders population, compared to child pornographers. **Results:** To date, data collection is ongoing. The results are currently analyzed and will be presented. **Discussion:** From a psychopathological point of view, child pornographers appear to be a separate sex offender category, with a subpopulation of sexually-oriented child molesters who use child pornography to feed their fantasies, reinforce their cognitive distortions, or in some cases use them as a substitute. They would thus constitute a separate type of offender with unique risks and needs. Identifying those at risk of assaulting children in this offender population is

essential in order to adjust the recidivism prevention tools and the most appropriate treatment for each case. **Conclusion:** It is important to be able to locate people who use illegal pornography. It seems at least as important to identify among them those who are at risk of sexual assault. Research on the characteristics of child pornography consumers must be pursued in order to better target the risk factors for acting out and provide insights into the most appropriate management of these deviant behaviors.

No. 86

Delusions of Weather Manipulation and Telekinesis in a Case of Folie à Deux

Poster Presenter: Hiran Cardoz, M.D.
Co-Authors: Krishen Persaud, Michael Esang, MB.Ch.B., M.P.H.

SUMMARY:

The most recent update to the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, removes shared psychotic disorder as a separate disease entity and includes it under other specified schizophrenic spectrum and other psychotic disorders. There it is described as "delusional symptoms in partner of individual with delusional disorder." [1] We present a case supporting this distinction, where a couple shared a delusion. Ms. S, a 27-year-old Chinese American female with a history of cannabinoid and alcohol use disorder and no other formal psychiatric history other than self-cutting since high school, presented to the emergency room under police arrest after destroying property at her rental home. She tested positive for cannabinoids on urine toxicology and admitted to almost daily cannabinoid use for two years prior to presentation. Upon evaluation, Ms. S was a poor historian secondary to disorganized thought process and notable thought blocking. She endorsed command auditory hallucinations to destroy rental owner's property in an effort to harm her for treating patient like patient's mother does. She attested to smoking marijuana on the night of the incident. During her evaluation she disclosed that she and her husband possess the power to manipulate the weather, move objects, predict and control people's travel behavior, and operate phone applications without physical contact. She also believed husband and Norma Jean are Jesus Christ because of their soul and spirituality. She was admitted to inpatient Psychiatry and husband called the unit to inform the treatment team that she had been having auditory hallucinations for two years. He then confirmed a shared delusion stating that they can affect the weather, she can affect people's behavior, and that it is a possibility he is Jesus. The patient was started on Risperidone and responded to titration. The treatment team met with her husband to discuss discharge planning, which included follow up with a dual-focus treatment program. The patient was subsequently discharged home to husband on Risperidone 2 mg orally every 12 hours. This case provides an opportunity to examine the nosology of shared psychotic disorder, its evolution as a disease concept, and the importance of a careful and culturally-sensitive risk assessment in such presentations.

No. 87

Treating Addiction in Jail: A Vivitrol Trial With a Cohort of Inmates

Poster Presenter: Jessica Bayner, M.D.
Co-Authors: Kelly E. Uwoghiren, M.D., Asghar Hossain, M.D., Javeria Sahib Din, Madia Majeed, M.D.

SUMMARY:

The prevalence of substance use disorders in the Unites States was most recently documented to affect 20.5 Americans 12 years of age or older, constituting of two million opioid prescription pill users. The resulting increase in mortality, crime and the impact on the healthcare system makes opioid dependence a substantially important issue. Moreover, the number of prisoners in the country with opioid dependence has significantly risen over time. The World Health Organization has recognized the need to to address the matter, and advised to start treating inmates prior to their release, in an effort to avoid relapse or death. The treatments that are offered in jails are varied, and policies differ in each facility. Currently available pharmacotherapeutic options for opioid dependence are opioid agonists, partial agonists, alpha-2 agonists, and opioid antagonists, the latter of which includes Vivitrol. Vivitrol is a long-acting depot formulation of naltrexone, an antagonist at the

opioid receptor. It is well tolerated, and has been approved by the FDA for the prevention of relapse to opioid and alcohol dependence. Vivitrol is injected on a monthly basis, which facilitates compliance in comparison to oral alternatives. However, many who would benefit from the medication do not have access to it, or do not receive multiple doses as recommended. This may be due to limitation of Vivitrol's availability, with respect to complications with insurance coverage, and prescribers' possible lack of familiarity with the medication. Other factors include patients' motivation to remain abstinent and utilize resources to help in their recovery. Our proposed project entails conducting research in a jail which has been approved to administer Vivitrol to their inmates. The population will be prisoners undergoing care in the jail's voluntary acute inpatient drug program, who will be given the option of receiving Vivitrol in the course of their treatment. Questionnaires will be distributed amongst the inmates, which will identify their drug of choice (opioid versus alcohol), and inquire about their willingness to start taking Vivitrol. Those who opt out of getting Vivitrol will be used as a control group. The inmates who choose to receive the injection will be asked whether they intend to continue getting it after being released from jail. We will follow up with the patients who were surveyed after several months, and ask about their cravings, rates of relapse, compliance, and any difficulties they encounter with the medication. The data will be analyzed to determine the efficacy of Vivitrol when offered in a jail setting. The results will add greater insight into the management of addiction and its intersection with forensics. This will be of value in addressing the clinical challenge of opioid dependence among incarcerated patients, which may also be applied to providing care for the community-at-large.

Not Guilty by Reason of Insanity: Now What?

Poster Presenter: Jessica Bayner, M.D.

SUMMARY:

The importance of providing quality and ethical care to psychiatric patients is unquestionable. However, there are instances in which policies are not updated to address mental health concerns for those in need of treatment, which also affect the greater population. Such an example is outlined in case of a patient living in New Jersey who became linked with a community hospital's outpatient clinic. A Hispanic male in his 30s, the patient was on KROL status, signifying that he was once arrested for various charges and ultimately deemed "Not Guilty by Reason of Insanity" (NGRI). As a result, he was mandated to undergo mental health treatment for 11 years, after he was evaluated and diagnosed with Schizoaffective Disorder. This was in lieu of serving time in jail, as is the case with others who are on KROL status (due to the Supreme Court of New Jersey's ruling in State v. KROL in 1975). KROL patients must appear for scheduled court hearings, at which point the Judge, Prosecution and Defense attorneys assess how often the patient needs to be monitored and when the next hearing should take place. In an effort to address to need for better monitoring of such patients, the writer sent a letter to the State Senator's office to request for more resources to better track such patients. Just as people who get released from jail have probation officers, it would behoove the community-at-large to have better monitoring of those under KROL status. After communicating with various county officials, it became apparent that there is a lot of fragmentation in the system that creates a gap through which many are liable to fall. For example, conflicts were revealed that exist between the Criminal Division of Superior Court and civil commitment hearings, when patients' were not tracked properly and resources were being burdened. The writer met with representatives from the County Prosecutor's Office, the County Adjustor, the County's Health and Human Services Center, and administration from the community hospital. All parties agreed that better collaboration was needed for the management of such NGRI patients. A proposal has since been made to create an accessible database to allow authorized entities to track KROL status individuals. Suggestions as to what to include are: details about the patients' scheduled hearing, their assigned Attorneys, names of the providers, and contact information of the specific Judge who is to be notified if the patient becomes noncompliant. The efficacy of such a database will be assessed and if successful, may serve as a model that can be implemented in other parts of the State. Further development of resources

may also lead to the creation of an official monitoring program for such patients to help them navigate the healthcare system as a whole. The mentally ill and the incarcerated are both underserved populations and as such, deserve advocacy to ensure proper treatment.

No. 89

The Use of Stimulants in Hoarding Disorder Comorbid With Depression: A Case Study

Poster Presenter: Dae Kim
Co-Authors: Aos Salah Mohammed Ameen, M.D., Nikhil Pillai, Panagiota Korenis, M.D.

SUMMARY:
Hoarding disorder (HD) is characterized by both a collection of excess items resulting in clutter and a difficulty in discarding excess items, causing significant impairment. Obsessive-compulsive disorder (OCD) is defined as recurrent and intrusive thoughts causing marked distress accompanied with repetitive compulsions. Hoarding disorder was classified as a subtype of OCD, until recently. HD is thought to differ from OCD as a defect in neurocognitive functioning such attention and nonverbal memory as well as in neural activity demonstrated by f-MRI. The prevalence of HD ranges from approximately 1.5% to 6% and first line treatment is often cognitive behavioral therapy (CBT). Mood disorders are often present with HD and OCD, with Major depressive disorder (MDD) as one of the most common co morbidities. There is no official recommendation for pharmacotherapy for HD, but some studies suggest reduction of the symptoms with SRIs, stimulants, or SRI augmentation in patients diagnosed with OCD with hoarding symptoms. Furthermore, studies suggest, depression not responding to first line treatment can be augmented with stimulants such as Methylphenidate. In this report, we explore the case of a 66-year-old Caucasian Male who was admitted to our inpatient psychiatric unit for major depressive disorder with suicidal ideation and co-morbid HD. He was treated with Sertraline for MDD. During his stay, his treatment was augmented with methylphenidate and a significant improvement in his symptoms was noted. This case report aims to support the notion that treatment of depression comorbid with HD can be augmented with stimulants. Furthermore, we aim to add to the medical literature of HD and the use of pharmacotherapy

No. 90

Moving to the Rhythm: A Rare Case of Obsessive-Compulsive Disorder

Poster Presenter: Geetha Chandrashekar, M.D.
Co-Authors: Meelie Bordoloi, M.D., David M. Ash, M.D., Garima Singh, M.D.

SUMMARY:
A 16yo female presented to the Autism clinic with her family saying, “she has a sway and really has to have music in her life”. This behavior caused her significant anxiety and stress. She had been bullied at school due to her compulsions. There was one time where her hair was cut and glue was poured in her hair. The urge to sway back and forth occurred with all types of music. In the presence of music, she even swayed while walking. Initially, she was able to control swaying in a public setting like restaurant but the urge continued to build up and create so much anxiety to a point where she had to leave the place early. She felt embarrassed about this behavior and it significantly limited her social functioning. Eventually she began to avoid going to places. She spent about two hours in a day swaying in her room to music. Music was played during the evaluation and after about 30 seconds, she was in visible distress from trying to control swaying. She denied history of seizures. She denied any symptoms of psychosis. On assessment, ASD was ruled out as patient did not have any deficits in social emotional reciprocity, non-verbal communication or developing or maintaining relationships. She was started on Sertraline 25mg daily and symptoms improved significantly. Intrusive musical imagery (IMI) is characterized by involuntary recollection of short, looping fragments of melodies, which can be triggered by exposure to any form of music. While for most people, IMI is not aversive, people who do experience distress and functional impairment, meet criteria for OCD. Musical obsessions are described as recurrent episodes of IMI that are persistent, intrusive, unintentional, and causing significant distress and functional impairment. Musical obsessions are often under-diagnosed because of limitations in assessment methods or mis-diagnosed as psychotic phenomena, and hence treated

ineffectively. It differs from musical hallucinations, in that, it is a form of imagery that the person recognizes as originating from his or her mind, and occurs in people who do not suffer from hearing disorder, seizures, delirium, psychosis, dissociative disorders, drug induced states or hypnagogic states. Like with other types of OCDs, musical obsessions are also accompanied by fear, compensatory or avoidance behaviors. It is suggested that these patients are most likely to benefit from SSRIs, clomipramine, CBT, exposure/response prevention, and distraction-based treatments.

No. 91

Mindfulness Based Cognitive Therapy for Obsessive-Compulsive Disorder: A Pilot Study

Poster Presenter: Yongjun Chen
Lead Author: Lu Lu
Co-Authors: Tianran Zhang, Jianyu Wang, Qing Fan, Haiyin Zhang, Fabrizio Didonna

SUMMARY:

Objective: Obsessive-Compulsive Disorder is a kind of mental disease which can cause pain and affect social function seriously. Mindfulness based cognitive therapy(MBCT) has been applied to the therapy and rehabilitation of various mental diseases as 'the third wave of cognitive behavior therapy'. As a pilot study, the study aims at exploring the curative effect and the mechanism of action of MBCT for OCD combining quantitive and qualitative study. Method: 12 mild to moderate Chinese OCD patients meeting DSM-? diagnosis who were recruited through Shanghai Mental Health Center were divided into 2 groups, accepting clinic treatment with MBCT. Each group conducted by 2 psychotherapists who have been trained of MBCT. There are 11 sessions in 10 weeks of MBCT for OCD with a length of 150 minutes in the nine sessions, 90 minutes in the third session with family members and 7.5 hours in the eleventh session, which were held at weekly in an outpatient setting. The primary outcome measure is Yale-Brown Obsessive-Compulsive Scale(Y-BOCS) and the Five Facet Mindfulness Questionnaire(FFMQ), the secondary outcome measures are Hamilton Anxiety Scale(HAMA) and Hamilton Depression Scale-24(HAMD24). All assessments were performed at baseline, mid-treatment (week 4), at the end of treatment (week 10). The process was recorded by observers, and each patient had a half-one hour interview before and after the treatment. Result: The result of quantitive research: compared with the baseline, patients got significantly lower total scores of Y-BOCS ($F = 4.594$, $P < 0.05$, effect size = 0.338), and the score of obsessive thought was reduced significantly ($F = 5.473$, $P < 0.05$), the score of obsessive behavior was not changed significantly. The patients had lower difference values of the HAMD scores ($F = 11.799$, $P < 0.01$) and the HAMA scores ($F = 7.442$, $P < 0.01$). The score of FFMQ was not changed significantly, including the aspects of observing, describing, non-judging and non-reacting, but the aspect of acting with awareness increased significantly ($F = 7.057$, $P < 0.05$). The results of qualitative research: group members believe that the beneficial factors of treatment mainly were the pleasure of communication, emotional support and practice guidance to the thoughts, the negative factors were the practice of mindfulness cannot be applied to their own specific obsessive-compulsive symptoms. Conclusion: (1) The effect of MBCT on the reduction of obsessive-compulsive symptoms and (2) the improvement of anxiety and depression has a significant effect, (3) the effect of obsessive-compulsive thinking is more significant, (4) The improvement of acting with awareness is the main development of the level of mindfulness. (5) The curative effect of MBCTfor OCD is mainly from correcting the thoughts and improving the awareness of the symptoms. This study laid the foundation for the next large sample of randomized controlled trials. Project supported by the National Natural Science Foundation of China (No. 81771460), Sub-project of Shanghai Science and Technology Committee "scientific and technological innovation action plan " of science and technology support projects in the medicine and agricultural field (No. 15411950203), Collaborative innovation research project in translational medicine of Shanghai Jiaotong University School of Medicine (No. TM201614), Scientific Project from Shanghai Health Bureau (No. 201740086), Shanghai Jiao Tong University supported by"the Fundamental Research Funds for the Central Universities" (No. 16JXRZ12).

Manualized Group Cognitive Behavior Therapy (CBT) for Obsessive-Compulsive Disorder (OCD):

Delivery to an Uninsured Community Population
Poster Presenter: Robert Clay Peterson, D.O.

SUMMARY:
Background: Cognitive-behavioral therapy (CBT) with exposure and response prevention (ERP) has been shown to be one of the most effective treatments for patients with obsessive compulsive disorder. Group Behavioral Therapy (GBT) is comparable to individualized therapy in treatment response rates. Despite this, there are few studies that evaluate CBT / ERP within a group model that allow for generalizability, particularly in an outpatient community setting. We proposed to implement an evidence based, manualized 12-week CBT group for OCD with clearly-defined goals and structure at the Adult Outpatient Psychiatric Clinic (AOPC) at LAC + USC Medical Center. Methods: Ten AOPC adult (age 31 – 79, 50% male) subjects with low socioeconomic status and OCD (diagnosed via DSMV criteria and Structured Clinical Interview OCD Module) were recruited. Twelve closed 60 minute groups were held weekly with co-investigators following the treatment manual, GBT for OCD (Van Noppen et al., 1997). Subjects were administered the Yale Brown Obsessive Compulsive Scale (YBOCS), Beck Depression Inventory (BDI), and the Beck Anxiety Inventory (BAI) at baseline, after session 6, and at the conclusion of the final group. A 10-question satisfaction survey was administered at the conclusion of the study. Results: Eight subjects averaged over 80% attendance during the study whereas 2 individuals were present less than 50% of the time and were thus excluded due to insufficient data. Overall, decreased values in participants' YBOCS, BAI, and BDI scores were observed and no participants reported worsening of OCD symptoms. Mean baseline YBOCS, BAI, and BDI scores were 25, 23.3, and 24 respectively, and 20.9, 21.8, and 16.5 respectively at the conclusion of the group. These scores yielded mean YBOCS, BAI, and BDI score reductions of 4.1, 0.5, and 5 points respectively, and median score reductions 2.5, 4, and 7 points respectively. Mean survey satisfaction scores (on a 1 – 5 point scale): group atmosphere (5), program helpfulness (4.9), program quality (4.9), therapist satisfaction (4.9), likeliness to recommend to a friend (4.9), treatment modality (4.8), educational material (4.6), exposure exercises (4.6), program length (4.3), comfort treating self individually following group (3.4). Conclusion: These results suggest that group based CBT / ERP is an effective treatment in a community setting as evidenced by the overall reductions in outcomes scores and high satisfaction by participants. The added benefits of GBT being a cost-effective, and less time-intensive treatment than individual therapy with further advantages of group cohesion and modeling make this a potentially valuable treatment modality in the community setting. Replication and further data analysis is needed to generalize these findings with a larger sample size and a control group.

No. 93
The Research of Interaction Between Inhibition Function and Emotion in Obsessive-Compulsive Disorder in China
Poster Presenter: Rui Gao

SUMMARY:
Objective: This research adopted Scale Assessment, emotion stroop task and expression inhibition task to study the inhibition function, emotion and their interaction of OCD.Methods: 30 OCD qualified with enter criteria were selected, and 30 health controls(HC) matched with OCD in gender, age and education were selected from advertising. Several scales and experiments were made on OCD and HC including general situation questionnaire, Y-BOCS, Y-BOCS-SC, HAMA, HAMD, BIS/BAS, emotion stroop task and expression inhibition task. Using SPSS to deal with the statistics. Results: 1. Scores of Y-BOCS, subscale of obsessions and subscale of compulsive behaviors of OCD were significantly higher than those of HC ($p=0.000$) . Scores of HAMA and HAMD on OCD were significantly higher than HC ($p=0.000$). Scores on the BIS subscale of OCD were significantly lower than HC ($p<0.05$). There was positive correlation between Y-BOCS and HAMA ($r=0.596$, $p<0.01$), Y-BOCS and HAMD ($r=0.522$, $p<0.01$). There was negative correlation between Y-BOCS and BIS ($r=-0.378$, $p<0.01$). There was positive correlation between HAMD and HAMA ($r=0.882$, $p<0.01$), and there was negative correlation between HAMD and BIS ($r=-0.319$, $p<0.05$). 2. Compared with HC, the reaction time was significantly higher in OCD ($F=855.06$, $p=0.000$). There was no difference among different kinds of emotional words in OCD ($F=0.391$,

p=0.759). There was no difference on accuracy between OCD and HC (F=0.414, p=0.520). There was a positive correlation between Y-BOCS and reaction time (r=0.104, p<0.01). 3. By analyzing the ratings of OCD and HC in different situations (inhibition, non-inhibition), this study found that the main effect of situation was significant (F=41.534, p=0.000), no difference was found between two groups (F=2.417, p=0.12) and the main effect of category of pictures was significant (F=612.708, p=0.000). In the non-inhibition part, there was no significant difference between OCD and HC (F=0.460, p=0.498). In the inhibition part, there was significant difference between OCD and HC (F=4.778, p=0.029), especially on negative pictures. There was a negative correlation between Y-BOCS and ratings (r=-0.138, p<0.01).Conclusions: 1. There was a inhibition deficit in OCD. Compared with HC, OCD had more anxiety and depression feelings. There was a significant negative correlation between depression and inhibition function. 2. Compared with HC, the inhibition of emotional words was poorer in OCD, however, there was no significant difference among all emotions. There was a positive correlation between the severity of OCD and reaction time. 3. OCD can regulate their positive, negative and neutral emotions by expression inhibition. Compared with HC, OCD had more powerful inhibition on negative emotions. There was a negative correlation between the severity of OCD and ratings.

Trichotillomania and Rapunzel Syndrome: A Case Report and Treatment Updates

Poster Presenter: Travis William Jones, M.D.

SUMMARY:

Trichotillomania, the compulsive urge to pull one's hair, can have a crippling effect on a patient's life. Ten percent of these patients go on to develop trichophagia, the compulsive eating of hair. In this case report, a 12-year old female presented to the ER with four days of abdominal pain, nausea, and vomiting. CT scan soon showed the presence of a small bowel obstruction. When the surgeons inspected the bowel during an exploratory laparotomy, they found the presence of a trichobezoar, or a mass of hair that had caused the small bowel obstruction. Rapunzel Syndrome is when a trichobezoar is found that extends from the gastric body beyond the pylorus into the duodenum. The Psychiatry Consult-Liaison team was consulted to provide further guidance. This patient was found to have started eating hair from a young age. When the patient was seven years old, the mother of the patient shaved the patient's head. After this, the patient allegedly stopped her hair picking and consumption. The patient denied eating hair since age seven and no bald spots were noted on the patient's head. Father of the patient noted that the patient recently started undergoing puberty and had demonstrated some oppositional behavior but he had not noticed the patient eating any hair. No other obsessive-compulsive symptoms were found on exam, and the patient had never sought psychiatric care before. The patient was offered an appointment in the Child and Adolescent Behavioral Health Clinic, but the parents of the patient refused to seek outpatient care at that time. The patient recovered from the operation and was discharged from the hospital. Given the presence of the large trichobezoar found during surgery, this patient was most likely still suffering from trichotillomania. This disorder is found in the Obsessive-Compulsive and Related Disorders category of the DSM-V. Although cognitive behavioral therapy is proven effective for trichotillomania, there is no clear proven first-line pharmacological agent. Mood stabilizers like lamotrigine and lithium have shown some effectiveness. One could also consider fluvoxamine, commonly used in obsessive-convulsive disorder. There has even been some effectiveness with N-acetylcysteine, and over-the-counter product. Other medications researched include methylphenidate, topiramate, valproic acid, naltrexone, olanzapine, and aripiprazole. This case report will examine the latest research in treatments for trichotillomania along with recent discoveries in pathophysiology, with the hope of aiding clinicians in treating the disorder to prevent the life-threatening Rapunzel Syndrome.

Developing a Measure to Assess Beliefs More Systematically: The Results of a Pilot Study of the Nepean Belief Scale (NBS)

Poster Presenter: Vlasios Brakoulias

SUMMARY:

Abstract Background: Abnormal beliefs are a central feature of several psychiatric disorders, e.g. persecutory beliefs in psychotic and borderline disorders, beliefs surrounding contamination in obsessive-compulsive disorder (OCD), and beliefs about body image in anorexia nervosa and body dysmorphic disorder (BDD). Assessing beliefs has not always been systematic in the literature with characteristics of beliefs such as conviction, strength, insight and fixity often used very loosely. DSM5 has attempted to improve the description of insight in several disorders (OCD, BDD, hoarding disorder) by introducing more detailed insight specifiers, i.e. good or fair insight, poor insight, or absent insight/delusional beliefs. Methods: The Nepean Belief Scale (NBS) was specifically designed to improve the consistency with which belief characteristics are assessed. The NBS was evaluated for interrater reliability, internal consistency, divergent and convergent validity and test re-test reliability in a pilot study involving two clinicians and 27 participants with OCD related beliefs. Results: There are benefits to clearly defining primary beliefs using prompts that encourage specific details and more precise definitions of belief characteristics. The 5-item NBS has an assessment time of less than 5 minutes. The interrater reliability was highly concordant (99.5%). Cronbach alpha coefficient for internal consistency was 0.87. The NBS was found to have excellent convergent and discriminant validity and the kappa for test-retest reliability was 0.98 (95% CI = 0.95 to 1.00). Conclusion: Preliminary data indicates that belief can be more effectively assessed using instruments with more clearly defined characteristics, such as the NBS. Although the NBS was assessed in participants with OCD, it may have wider utility in assessing beliefs associated with other obsessive-compulsive related disorders, somatic symptom disorders and psychotic disorders. This study was supported by grants from the Nepean Medical Research Foundation, the Pfizer Neuroscience Grant scheme and The University of Sydney.

No. 96

Obsessive-Compulsive Disorder in a 19-year-old adolescent with Turner Syndrome

Poster Presenter: Surinder Moonga

SUMMARY:

Obsessive-Compulsive Disorder (OCD) in patients with Turner syndrome (TS) 45,X monosomy is an uncommon neuropsychiatric presentation that has not been well characterized in the scientific literature. Though no clear psychiatric component is syndromic to TS, the clinical manifestations of certain neuropsychiatric disorders, including mood, anxiety and eating disorders, have all been well documented in patients with TS. However, the presence of OCD in these patients has not been previously described. This report details a 19-year-old TS patient who presented with OCD since the age of 13, comorbid with several other psychiatric pathologies, including bipolar I disorder, anorexia nervosa and Attention Deficit Hyperactivity Disorder (ADHD). Additionally, this report will discuss those co-morbidities in relation to the patient's genetic syndrome and discuss the contribution it makes to her multiple disabilities diagnosis as well as her patient-specific therapy. Patients with Turner syndrome often present to treating physicians for overwhelming somatic complaints, likely resulting in poor recognition of psychiatric disorders. Thus, OCD may be significantly underdiagnosed in TS patients and should be considered by clinicians treating TS patients who will often only describe somatic systems disorders as their chief complaints. A case report of a TS patient with OCD and the utilized treatment approach is presented here.

No. 97

Posttraumatic Stress Disorder in an Adolescent With Inflammatory Bowel Disease-Related Bowel Surgery

Poster Presenter: Surinder Moonga

SUMMARY:

A fifteen-year-old female with Crohn's disease, diagnosed at age six, presented to the psychiatrist for evaluation of "blackouts". These episodes had been occurring for the previous two years, developing shortly after an ileostomy procedure. These were gradually becoming more frequent and severe. She describes her first episode as follows—"I was sitting at the breakfast table as usual when I suddenly felt myself leave my body, feeling spaced out and unable to talk". Following these episodes,

which would last up-to ten minutes, the patient would return to her baseline. The patient recalled the entire event, saying she had no control over her extremities and could only “see black”. She has had extensive work up for these episodes with negative laboratory findings, brain imaging and multiple video electroencephalograms. On review of her medications, the patient was not on steroids, methotrexate and/or infliximab. She also denied any substance use. Vedolizumab was the only medication taken regularly by the patient during this two-year-period and it was not a recent addition to her regimen. The patient returned to the hospital multiple times for medical evaluation over the next two years and was finally referred for psychiatry evaluation given lack of other explanations for her symptoms. Upon assessment, she described a long history of Crohn’s disease and related stress. After her ileostomy, she began feeling anxious and hyper-aware of her surroundings. Any reminder of her surgery would result in physiological arousal—sweating, “tingling” and abdominal pain. She would avoid looking at her bag, asking her caregivers to change it. She also described flashbacks and nightmares related to her surgery. She denied any past psychiatric history prior to her bowel surgery. Her symptoms persisted even after ileostomy reversal. Given supporting evidence from our patient’s history, diagnosis of PTSD was suspected. For confirmation, the Child PTSD Symptom Scale (CPSS) was administered, with higher scores indicting greater functional impairment. On initial presentation, her part 1 score was 41 (max 51, min 0) and part 2 graded YES 6 NO 1. Symptoms of hypervigilance, avoidance and negative alterations in mood and cognition stood out. She did not meet criteria for any psychiatric disorders other than PTSD. Her symptoms were treated with sertraline, gradually increased to a dose of 100mg, along with cognitive behavioral therapy (CBT). The patient tolerated sertraline well with no reported gastrointestinal side effects. CPSS, administered after two months of treatment revealed a part 1 score of 21 and part 2 graded YES 3 NO 4; signaling significant improvement and remission from PTSD. The patient’s nightmares, hypervigilance and depersonalization symptoms completely resolved. Over six months from initial presentation, the patient remains in remission.

No. 98

Prolonged Grief, Posttraumatic Stress, and Depression Symptoms After Loss: Co-Occurrence, Temporal Relationship and Key Symptoms

Poster Presenter: Manik Djelantik

SUMMARY:

Introduction: Mental health problems following a loss can result in heterogeneous symptomatology that may include symptoms of Prolonged Grief Disorder/Persistent Complex Bereavement Disorder (PGD/PCBD), Post-Traumatic Stress Disorder (PTSD), and Major Depressive Disorder (MDD). The co-occurrence, temporal relationship and the key-symptoms of these three disorders in bereaved individuals are still relatively unexplored. Information about these issues is beneficial in developing new strategies in the care of bereaved individuals. Methods: In the first study, using data from 496 Dutch bereaved persons who filled in questionnaires assessing PGD/PCBD, PTSD and MDD, we conducted a latent class analysis to identify different symptom classes and predictors of classes. In the second study, using data from 204 Dutch bereaved persons, who filled in questionnaires in the first and second year after their loss, we conducted a cross-lagged analysis to examine temporal relationships between PGD/PCBD and PTSD . In the third study, using data from 166 Dutch bereaved individuals, we conducted a latent class analysis to identify classes of bereaved individuals with similar trajectories of PGD symptoms between two time points (resp., 6 months and 18 months). Next, we used Receiver Operating Characteristic (ROC) analysis to examine which early symptoms best predicted membership of the class with a problematic grief trajectory. Results: In the first study, we found three different classes: a resilient class, a PGD class, and a combined PGD/PTSD class. Violent cause of death, loss of a child, and loss of a partner were associated with membership of the combined PGD/PTSD class. In the second study, we found that PGD symptoms may precede PTSD symptoms after bereavement. In the third study, we found two classes with a problematic grief trajectory in adults over the first two years after a loss. Daily endorsement of yearning, feeling stunned, anger and/or feeling that life is empty best predicted

membership of these two classes. Discussion: These three studies increase our understanding of the course and predictors of emotional distress following bereavement. This knowledge can inform the development and refinement of assessment and intervention methods, specifically directed towards vulnerable subgroups of bereaved individuals. Topics: Bereavement, Post Traumatic Stress Disorder, diagnostics. Co-authors: A.A.A.Manik J. Djelantik, MD, Geert E. Smid, MD PhD, Rolf J. Kleber, PhD, Paul A. Boelen, PhD

Influence on FKBP5 Polymorphism on Structural Changes and Psychological Symptoms of the Brain in Posttraumatic Stress Disorder

Poster Presenter: Min Jin Jin

Co-Authors: HanNa Seo, HeeJung Jeon, Seung-Hwan Lee

SUMMARY:

FK506-binding protein 51 (FKBP5) is known to be an important modulator of stress responses, and a single nucleotide polymorphism of rs1360780 in the FKPB5 gene is associate with a predisposition to developing post-traumatic stress disorder (PTSD). This study examined the interactive effect of the diagnosis of PTSD and FKBP5 rs1360780 allelic variants on volume changes of the entire brain. Sixty-eight PTSD patients and 63 healthy controls were included. T1-weighted structural magnetic resonance imaging, FKBP% rs1360780 genotyping through blood assessment, and psychological and neuropsychological assessments were administered. The volume of cortical and subcortical regions were analyzed using FreeSurfer and 2x2 ANCOVA was analyzed by SPSS 21.0. Significant interactive effect of genotype-by-diagnosis were observed for the volume of left precentral gyrus, left postcentral gyrus, and left lingual gyrus. The T allele was associated with significant volume reduction in these regions with PTSD patients, whereas T allele was associated with significant volume increase only in left lingual gyrus with healthy controls. The volume of those regions were negatively correlated with social support and positively correlated with rumination and PTSD symptoms only in people without T allele. In contrast, the volume of those regions were negatively correlated with experiential avoidance, positively correlated with social support and PTSD symptoms. Results of this study suggest FKBP5 gene could influence on changes of several brain regions and the psychological characteristic related with brain changes. This study was supported by a grant from the Brain Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Science, ICT and Future Planning (NRF-2015M3C7A1028252).

No. 100

Psychiatric and Neurocognitive Consequences of Exposure to Hurricane Katrina and Relocation

Poster Presenter: Phebe Mary Tucker, M.D.

Co-Authors: Christopher Nguyen, Ph.D., William D. Ruwe, Ph.D., Psy.D.

SUMMARY:

Background: Survivors of natural disasters, such as hurricanes, are at risk for mental health sequelae such as post-traumatic stress disorder (PTSD) and depression. A vast body of literature has examined the neurobiological consequences of PTSD and other sequelae from diverse trauma types among combat veterans and civilians. Previous studies from our laboratory revealed the presence of increased pro-inflammatory cytokines among survivors of Hurricane Katrina with PTSD and autonomic reactivity to trauma cues. To expand our understanding of how stress of hurricane exposure affects survivors, we examined its neurocognitive sequelae, to add to the growing literature documenting various decrements in functioning in trauma survivors. Methods: Survivors of Hurricane Katrina and/or ensuing floods relocated to Oklahoma (N = 33; Mean age = 27.2 +/- 12.6 years) were recruited and matched to control participants by age, gender, and years of education (N = 28; Mean age = 25.6 +/- 10.5). All participants completed neurocognitive tests assessing for processing speed (Trail Making Test Part A [TMT-A]), mental flexibility (Trail Making Test Part B [TMT-B]), sustained attention (Conner's Continuous Performance Test - 2 [CPT-2]), and learning and memory (Rey Auditory-Verbal Learning Test [RAVLT]). Symptoms of PTSD were quantified by the Clinician-Administered PTSD Scale (CAPS). The Beck Depression Inventory-II (BDI-II) was used to assess depressive symptomatology. Results: To test for any

mean level differences on the cognitive and affective variables, t-tests were conducted. There were no statistical differences between the participant groups on age, gender, and education. Participants in the survivor group exhibited weaker performance on the TMT-A (t [58] = 2.43, p = .02), TMT-B (t [58] = 2.19, p = .03), and CPT-II response time (t [58] = 2.04, p = .05), but performance was comparable between the two groups on the RAVLT. When comparing scores on the psychometric measures, survivors scored higher on the CAPS (t [59] = 4.41, p = <.001), as well as the BDI-II (t [59] = 4.40, p = <.001). Follow-up univariate analysis of variances among each cognitive variable revealed only a significant main effect on the CPT-II response time, F (1. 37) = 4.871, p = .006. Conclusion: We found significant psychiatric and neurocognitive sequelae among relocated Hurricane Katrina survivors when compared with control participants, such that they exhibited poorer performance on tests of processing speed, sustained attention, and mental flexibility, in addition to higher emotional distress as indicated by measures of PTSD and depression. When controlled for PTSD and depression symptoms, survivors exhibited slower responses on a measure of sustained inattention (an indication of inattentiveness) above and beyond the effects of chronic psychological distress. Results underscore that cognitive problems in addition to neurobiological changes may complicate hurricane survivors' recovery.

Evidence-Based, Collaborative Care Model for Treating Chronic Military-Related PTSD: Three Decades of Experience at the Miami VA PTSD Clinic

Poster Presenter: Nils C. Westfall, M.D.
Co-Authors: Samantha B. Saltz, M.D., Mousa Botros, M.D., Rebecca M. Arana, M.D., Daniella David, M.D.

SUMMARY:
Former military personnel are commonly affected by PTSD and they are more frequently and severely affected by it than the general population (1, 2). More than 50% of patients with PTSD have comorbid psychiatric disorders (e.g., mood, anxiety, substance use) (3) and many exhibit maladaptive coping (e.g., avoidance, isolation) and other treatment-interfering behaviors. PTSD and combat-related traumatic stress are independently associated with heightened mortality rates and increased risk of numerous chronic medical conditions (e.g., cardiovascular disease, diabetes) (4). About one-third of all PTSD cases follow a chronic course, though military-related PTSD tends to be more severe, treatment-refractory, and chronic than average and, thus, multimodal, collaborative treatment is often indicated. Our PTSD interdisciplinary clinical team, which is part of a Veterans Affairs network of outpatient clinics specializing in PTSD, provides evidence-based psychotherapy (individual and group) and pharmacotherapy to veterans and other military personnel with chronic PTSD, whether combat- or noncombat-military-related (e.g. military sexual trauma, accidents), to help them optimize symptom management, achieve remission, and improve function in all domains of life. After completing an information session, the diagnostic screening, and orientation, patient-involved decision-making is used to develop a multimodal, collaborative treatment plan integrating the management of comorbid diagnoses, psychosocial stressors, and other important factors. Patient-provider teams may select from a number of different evidence-based individual (i.e., cognitive processing therapy, prolonged exposure, acceptance and commitment therapy for depression, cognitive behavioral therapy for depression and insomnia, and dialectical behavior therapy) and group (e.g., Recovery [various topics], Seeking Safety [substance abuse], military sexual trauma, anger management, CBT for insomnia, cognitive behavioral therapy for depression, mindfulness-focused, Wellness Recovery Action Planning) psychotherapies. All patients are evaluated by a psychiatrist and, if indicated, offered evidence-based pharmacotherapy. Patients with comorbid substance use disorders follow a unique treatment path which integrates therapists and pharmacologists specializing in that area. In the last 16 years, active patient numbers steadily increased from 519 in 2002 to a high of 3,021 in 2014, before decreasing to 2,525 in 2017. Current patients include veterans of every major combat theater since WWII. Of note, psychiatry and psychology trainees have been rotating in the clinic since its inception. Here we present in greater detail this highly successful program that has been improving the lives of

veterans and other military personnel with chronic PTSD and preparing mental health professionals to carry on its vital mission for nearly three decades.

Prevalence and Demographic Data of Medical Comorbidities Associated With PTSD: A Performance Improvement Project
Poster Presenter: Viviana Ines Chiappetta, M.D.
Co-Authors: Luisa S. Gonzalez, M.D., Panagiota Korenis, M.D., Monica Evelyn Badillo, M.D., Aos Salah Mohammed Ameen, M.D.

SUMMARY:
The past decade of research has provided evidence demonstrating that individuals with posttraumatic stress disorder (PTSD) present with an increased number of health complaints, suffer from more physician-diagnosed medical conditions, and exhibit higher health care utilization. PTSD has been associated with an increased risk for a number of adverse health conditions, including the development of major chronic diseases, such as hypertension, obesity and type 2 diabetes. These conditions represent a significant public health problem that is strongly associated with increased disease burden and mortality. A performance improvement project was conducted on all newly admitted patients over a two month period to our inpatient psychiatry service. We collected baseline data which identified not only the prevalence of PTSD but also the medical comorbidities of our patients. Despite knowing that there is an increased incidence of medical comorbidities in patients with PTSD, it is uncertain how this affects the treatment planning and patient's outcome on the inpatient setting. As such, the identification of potentially modifiable mechanisms linking PTSD and other chronic conditions is needed. Continued research in this area is necessary to help guide prevention and treatment efforts aimed toward reducing morbidity and mortality in those with PTSD.

No. 104
Hurricanes Katrina, Ike, Sandy, Harvey and Irma: Storm-Specific Exposures to Trauma and Loss in Relation to Psychopathology
Poster Presenter: Zelde Espinel, M.D.
Co-Authors: Mackenzie Jones, James Shultz, Taylor Johnson

SUMMARY:
Background. Human population exposure to the hazards associated with five memorable Atlantic Basin hurricanes - Katrina (2005), Ike (2005), Sandy (2012), Harvey (2017) and Irma (2017)– resulted in mortality, psychological distress, and psychopathology. Each of these storms had a distinctive hazard profile. Therefore, the storm-affected populations experienced different types of exposures to physical hazards during impact and adversities in the aftermath. The peer-reviewed research literature regarding the psychological consequences of tropical cyclones striking human populations has been enriched based on well-designed studies conducted with survivors of these powerful storms. Analyses presented here examine the hazard profile of each storm in relation to the storm-specific stressors and the psychiatric outcomes observed. Methods. Historical analyses of National Hurricane Center archival data and storm summaries prepared by expert atmospheric scientists allow us to describe the type, intensity, and duration of hurricane hazards. From these data, a detailed hazard profile is constructed for each storm. The disaster psychology literature is reviewed to create a matrix of psychological stressors associated with human population exposures to tropical cyclones and to identify the salient stressors for each of the five case examples of U.S. hurricanes. The review focuses intensively on the sizeable body of research published on these four storms. Emphasis is placed on identifying prominent psychological stressors associated with the pre-impact warning and preparedness phases (stressors associated with evacuation and sheltering), the impact phase (direct exposures to storm hazards), and the post-impact recovery and reconstruction phases (losses, hardships, and life disruptions). The literature is reviewed to elucidate the psychiatric outcomes in relation to exposures to trauma and loss. Results. Each of these four storms had a unique hazard profile in terms of the exposure of the storm-affected population to wind hazards (hurricane winds, tornadoes) and water hazards (storm surge,

coastal surge, deluging rains, river and overland flooding). In turn, community vulnerabilities and human population exposures to these hurricane hazards yielded different stressor matrices. Psychiatric outcomes; including the types, rates, duration, and severity of psychopathology; relate to each storm's novel constellation of exposures to potentially traumatic hazard events during storm impact and to the life-changing losses and adversities that are experienced following the storm. Conclusions. Each disaster has a unique signature. Even disaster events of similar genre – in this case, each of the five disasters were tropical cyclones originating in a single (Atlantic) hurricane basin within the span of 12 years – may produce markedly different psychiatric outcomes depending upon the complex dynamics of the hazard profile, community vulnerability, and population exposure.

Amoxicillin-Induced Mania: A Case Report
Poster Presenter: Jordan Harrison Rosen, M.D.

SUMMARY:
Antibiotics are an uncommon but documented (1) caused of both mania and delirium with a case literature detailing the latter more significantly. While the pathophysiology is poorly understood in mania, beta-lactam drugs have a suspected anti-GABA-ergic role in inducing a delirium often characterized by hyperreflexia, myoclonus and seizures. (2) This same mechanism seems a plausible explanation for how these agents could cause mania. In this case, a 54-year-old man was exposed to amoxicillin multiple years apart and developed classic symptoms of mania both times despite no evidence of mood episodes throughout the rest of his life. The second exposure was accompanied by signs of hyperreflexia and left him with persistent symptoms that eventually responded and went into remission with the induction of valproate.

No. 107
Challenges of Medical Clearance Through Clinical Cases
Poster Presenter: Michael Stephen Peroski, D.O.
Co-Authors: Bhinna Pearl Park, M.D., Marissa A. Flaherty, M.D.

SUMMARY:
Medical clearance for psychiatric treatment is the process by which a patient with symptoms presumed to be psychiatric in origin is evaluated for severe medical illness that could preclude their admission to an inpatient psychiatric unit. This process is highly variable, depending on the hospital system, the constraints of the psychiatric unit to which the patient may be admitted, and its presentation in the medical literature. What makes this more challenging is that there does not appear to be a consensus in the literature on how to medically clear a patient for admission to a psychiatric unit. We present three cases in which patients were medically cleared but later were found to have acute medical causes of their psychiatric symptoms or complications to their psychiatric treatment causing transfer off of a psychiatric unit. These cases include a geriatric patient with new delusions subsequently found to have pancreatic cancer; a patient with psychosis subsequently found to have temporal lobe epilepsy; and a patient determined to have severe cellulitis underlying their reported "depressive" symptoms. Careful attention will be paid to the process of medical clearance in these cases and how to generally improve the process of medical clearance. The process of medical clearance at our medical system will be discussed and the literature regarding this process will be reviewed extensively. Attention will be paid to aspects of the process at our institution that are generalizable and aspects of this process that may vary from institution to institution. This process also varies depending on whether the patient is coming from an outside hospital, from an emergency department, or from a medical floor facilitated by consultation liaison psychiatry. Unique aspects of the process within each of these situations will also be discussed. Lastly, we will discuss how existing policies interface with this process, including professional organization recommendations and EMTALA.

No. 108
Health Advocacy and Policy for Residents: A Solution for Resident Burnout?

Poster Presenter: Sabina Rajesh Bera, M.D., M.Sc.

SUMMARY:
Education surrounding health policy and advocacy training has rarely been proposed as a solution for resident burnout, and minimal studies touch on this subject. However, participating in health advocacy may lead to engagement and fulfillment as a member of an effective medical organization. Limited studies have suggested that medical students and residents feel empowered after engaging in advocacy efforts, and one study suggested that the residents surveyed believed health advocacy was core to their training. Residency programs currently do not generally require residents to engage in these activities. To our knowledge, ours is the first study to assess the ease of access by which a resident may learn about advocacy opportunities by specialty. Residents often use mobile devices to communicate and stay connected as well as desktops or laptops while at work, which we incorporated into our study. All major specialty organization websites were examined for the availability and ease of identifying advocacy efforts by the organization, current events affecting their patients, and health advocacy opportunities for residents. This was performed by a pre-medical undergraduate student with no prior exposure to specialty websites. This data was then compared with the available statistics on the rate of resident burnout by specialty. Every major organization's website was found to have a section clearly dedicated to advocacy, and most were found on mobile devices and laptops within 5 seconds. Locating the active advocacy efforts of the majority of organizations were identified in under 60 seconds on both devices, with 6 of 11 organizations mentioning the Affordable Care Act. 8 of out of 11 highlighted information regarding Hurricane Harvey on their homepage. All organizations also had opportunities for resident involvement, which ranged by type. For example, the American Academy of Emergency medicine, Family Medicine, and Neurology were identified to have advocacy opportunities open to all its members, however did not offer any specific programs for only residents. These programs took significant difficulty to find, ranging from twice to 150 times longer. There was no significant difference in identifying information on mobile and laptop devices. It is refreshing to know all organizations have advocacy efforts, however they may consider making health policy education for residents as easily identifiable. We found that residents would have to dedicate up to 5 minutes to locate these opportunities. Although the availability and ease of identifying advocacy efforts does not reveal a corresponding relationship to resident burnout by specialty, it is worth nothing that that the 3 specialties without specific opportunities for residents are in the top 10 specialties that experience the most burnout. In future studies, a more thorough investigation should be taken to examine if residents involved in advocacy activities are less likely to suffer burnout.

No. 109

Seizure Monitoring in Electroconvulsive Treatment

Poster Presenter: Emma Gustafsson
Co-Author: Niclas Bengtsson

SUMMARY:
It is generally agreed that induction of a generalised epileptic seizure is a prerequisite for treatment effects in electroconvulsive treatment. Mostly, seizure quality is evaluated by visual inspection (symmetry of seizure) and observed seizure duration. In this naturalistic follow up study we investigated if a manualized algorithm for seizure quality monitoring could be useful for prediction of outcome and side effects. All patients started on ECT treatment at the University Psychiatric Clinic in Umeå under 2016 were included in the study. ECT treatment was guided by a treatment algorithm (based on patients age and gender) – guiding stimulation strength over the treatment series and change of electrode placement (unilateral versus bilateral) when necessary. The algorithm for seizure quality monitoring included signs of brain-stem activation (rise in heart rate, rise in blood pressure and flushing over chest and face). It also included seizure duration (observed clinically and estimation of epileptic activity on EEG), any deviation from symmetric seizure activity and occurrence of postseizure EEG suppression. A composite index of seizure quality was calculated (0-6). Evaluation of outcome and side effects for the whole ECT series was done by MADRS (Montgomery Åsberg Depression Rating Scale) and the memory difficulty

item of the CPRS (Comprehensive Psychiatric Rating Scale). We also recorded occurrence of confusion between ECT treatments. Possible relations between seizure quality and outcome measures, occurrence of side effects and complications were examined.

No. 110
ECT and Catatonia
Poster Presenter: Krupa Pathak, M.D.
Co-Authors: Fnu Syeda Arshiya Farheen, M.B.B.S., Rajesh R. Tampi, M.D., M.S., Venkatesh Sreeram

SUMMARY:
Introduction: Catatonia is a syndrome of mood dysregulation associated with many different illnesses. The signs of catatonia include posturing, mutism, negativism, rigidity, stupor, cataplexy, waxy flexibility, mannerism, sterotypy, grimacing, agitation, echolalia, and echopraxia. Electroconvulsive therapy (ECT) is a procedure consisting of small electric current passing through the brain inducing a brief seizure used to treat different mental illnesses, including treatment resistant depression, severe mania, and catatonia. Objective: The purpose of this review is to evaluate the efficacy of ECT as a treatment for catatonia due to several conditions (i.e. schizophrenia, depression, medical conditions, etc). Methods: We performed a literature review of Pubmed/Medline and Cochrane library through August 21st, 2017 using the keywords “ECT” and “Catatonia”. The search was not restricted by the age of the patient, or the language of the study. However, in the final analysis, the studies involving patient that were published in English translations were included. In addition, we reviewed the bibliographic databases of published articles for additional studies. Results: The systematic review of literature identified a total of eleven articles of which only four met the inclusion criteria. The first article studied ECT in patients with catatonia and in patients with bipolar disorder. The second article evaluated the short term outcomes of ECT. The third article discussed the effects of various treatments in patients with catatonia and compared other pharmacological treatments with ECT. The fourth article studied the effects of ECT in schizophrenia (catatonic and other types of schizophrenia). The side effect profiles were the same in all the articles. Conclusions: ECT alone or in combination with pharmacotherapy is recommended for the treatment of treatment resistant catatonia. It is implicated through this review that there is not much evidence based research done to support the efficacy of ECT in catatonia and this warrants for more RCTs and systematic reviews to facilitate ECT.

No. 111
Treatment of Psychosis and Agitation in Lewy Body Dementia With ECT
Poster Presenter: Shizhen Jia

SUMMARY:
Patient is 61 year old gentleman who presented with uncontrolled psychosis and agitation for 6 months.

No. 112
Treatment of Lewy Body Dementia Related Psychosis and Agitation With Electroconvulsive Treatment
Poster Presenter: Shizhen Jia, M.D.
Co-Author: Obiora Edward Onwuameze, M.D., Ph.D.

SUMMARY:
Lewy Body Dementia (LBD) is the second most common major neurocognitive disorder, after Alzheimer’s (Weintraud and Hurtig, 2007). It is neurodegenerative, progressive and debilitating with similar features as Parkinson’s disease (PD), diagnosed by cognitive decline prior or within 1-year onset of motor disturbances (Boot. et. al., 2013). Presence of visual, auditory hallucinations and early psychosis with fluctuating coursebis common (Burgut and Kellner, 2010). Gait instability; postural hypotension and depression are also prevalent. There is no effective treatment to slow progression. Anticholinesterase inhibitor, antipsychotics and antidepressants are some options to manage symptoms (Boot. et. al., 2013). Each pharmacological intervention comes with side effects and severe delusions with psychosis is often difficult to treat due to neuroleptic sensitivity in LBD patients (Burgut and Kellner, 2010). ECT has been shown to be effective in treatment resistant depression, psychosis and motor dysfunction in other psychiatric and neurological disorders (including PD) but usage in LBD has not been studied extensively (Burgut and Kellner, 2010). The improvement in motor and

psychiatric symptoms could significantly improve quality of life. This clinical case showcase the efficacy of ECT in patient with LBD that presents with psychosis, agitation and motor dysfunction. 61-year-old man presented with treatment resistant psychosis and agitation in association with Lewy Body Dementia. Patient has been experiencing years of neuro cognitive decline which preceded his motor disturbances, rapidly deteriorating in the last 4 years. Last 6 months before admission patient became aggressive, psychotic with hallucinations and physically threatening. Insomnia, aphasia, frequent falls and orthostatic disturbances also present. Patient has tried adequate dose and duration of Seroquel, Risperdal, Zyprexa, haloperidol, Ativan to manage psychosis and agitation without benefits. Clozapine discussed with POA as best option for LBD but was refused due to concern of side effect. Ativan was also titrated down due to falls. Patient responded to internal stimuli, experienced AH and VH, constantly agitated, restless and unable to be redirected. Patient also had frequent falls, poor oral intake due to agitation and inability to remember to swallow. ECT was started for treatment resistant psychosis and agitation. 6 acute series sessions done and weekly maintenance for 4 weeks, planned for once every 2 weeks twice and further treatment to be determined. He became compliant with medications, increased oral intake, better verbal communication. Patient continue to be pleasantly confused but is able to voice some needs with improved verbal communication, no longer aggressive or agitation and he has regained ability to respond appropriately to more social cues. Significant improvement of quality of life and able to be discharged to long term care facility.

No. 113

Treatment of Agitated Catatonia With Electroconulsive Treatment

Poster Presenter: Shizhen Jia, M.D.
Co-Authors: Rucha Haily Dalvi, M.B.B.S., Obiora Edward Onwuameze, M.D., Ph.D.

SUMMARY:

Joseph (1999) described agitated catatonia as "marked by excessive and purposeless motor activity and mimicry. Mutism, stuttering, and echolalia (repetition of what has just been said by another) represent speech and language problems associated with catatonia." (as cited by Marvel and Paradiso, 2004). Agitated catatonia is most often successfully treated with benzodiazepines such as Lorazepam (Cottencin et al., 2007). Patients below the age of 60 with pharmacological treatment resistant agitated catatonia have shown to improve with ECT (Haq and Ghaziuddin, 2014). Suzuki et. al. (2003) reported nine elderly schizophrenic patients with catatonia responded to to ECT, it was unclear if it was agitated catatonia. ECT has not been well documented in treatment resistance agitated catatonia of geriatric patients in previous literature. Therefore, this particular clinical case would assist in exploration of appropriate treatment for agitated catatonia in the elderly, in particular those with major neurocognitive disorder that does not respond to medications. 78 year old man presented with agitation, frequent falls, AMS and anxiety. He has hx of major neurocognitive disorder, probable Alzheimer type since 2008. He was perspiring profusely, repeated motor movement, echolalia and muscle rigidity that prevents him from resting. Significant confusion was also notable with uncontrolled agitation despite risperdal, prolixin and seroquel trial at adequate doses. Zoloft added for depression with minimal effect. Keppra discontinued due to relation to agitation and confusion side effect. Depakote was started for mood stabilization. Ibuprofen and Norco were placed for pain likely due inability to relax his muscles. There was significant bilateral edema of Lower extremities due to agitated catatonia induced immobility that was painful. Venous Doppler ruled out DVT. Antipsychotics were discontinued for a period of time due to concern with NMS with elevated CPK. Ativan started and changed to Klonopin and marinol was also tried to help with anxiety and inability to relax with minimal response. Patient was requiring complete care, minimal interaction and in constant distress. ECT was then proposed to family who agreed. With 6 acute sessions, the patient significantly improved, able to be conversational, responds to questions appropriately. He was calm and had decreased motor agitation. The patient regained his ability to ambulate with a walker. Thought process improved. His Klonopin and Norco usage also decreased as he improved. He was discharged to NH but decompensated and returned to hospital and

received maintenance ECT treatments for a few weeks where patient did well. However, towards the end of his second stay patient became restless and UTI was found. POA and family refused further intervention including ECT and requested full comfort care. With pain medications and comfort measures patient was not in distres

Clinical and Biomarker Correlates of Dysnomia in Alzheimer's Dementia and Mild Cognitive Impairment: Validation of the Thai-Version Boston Naming Test

Poster Presenter: Daruj Aniwattanapong, M.D.

SUMMARY:

Background: Impairments in the Boston Naming Test (BNT), which measures confrontational word retrieval, frequently accompanies Alzheimer's dementia (AD) and may predict a more rapid progression of illness. This study aims to validate the Thai version of the BNT (T-BNT) and delineate the clinical and biomarker characteristics of dysnomia in patients with AD and mild cognitive impairment (MCI). Methods: This cross-sectional study recruited patients with AD, diagnosed according to NINCDS-ADRDA criteria (n=60), MCI, diagnosed using the Petersen criteria (n=60), and healthy controls (n=62). All participants were evaluated with the T-BNT, the Mini Mental State Examination (MMSE), the Verbal Fluency Test (VFT) and the Word List Memory (WLM) tests. Apolipoprotein E polymorphism and serum levels of folic acid, cholesterol and triglyceride were analyzed. Internal consistency, concurrent and discriminant reliability of the T-BNT were examined. Results: This study developed a T-BNT, which yielded good internal consistency (0.92), a one-factor unidimensional structure, and adequate concurrent and discriminant validity. Lower scores on the T-BNT highly significantly predict AD, but not MCI, and are positively associated with VFT and WLM test scores. The ApoE4 allele, lower folate levels and an increased triglyceride/HDL-cholesterol ratio were independently associated with significantly lower T-BNT scores. Conclusion: This study validated the T-BNT. Dysnomia as measured with the T-BNT is associated with impairments in semantic and episodic memory and with AD, and is influenced by biomarkers, which are known to modify memory via different mechanisms.

No. 115

Major Neurocognitive Disorder Presenting as Exacerbation of Mood Symptoms

Poster Presenter: Deepa Anand
Co-Author: Caesa Nagpal, M.D.

SUMMARY:

Major Neurocognitive disorder is an acquired decline in cognitive functioning which according to DSM-5 requires an evidence of significant cognitive decline from a previous levels of performance in one or more cognitive domains namely learning and memory, language, executive function, complex attention, perceptual-motor and social cognition. We report a case of a 58-year old female with a history of Bipolar disorder diagnosed 7 years ago, presenting with exacerbation of mood symptoms which was found to be a presentation of a major neurocognitive disorder. Method: (Case Report): Ms. H, a 58-year-old Caucasian female with a past history of Bipolar disorder was admitted to an acute psychiatric facility for depression and suicidal ideations. She also presents with auditory hallucinations and visual hallucinations of "people walking and talking around her." On exam, she was very labile with a disorganized thought process and also a poor historian. She had a past medical history of myocardial infarction. Clinical examination was unremarkable. Laboratory results and urine-analysis were within normal limits. She was started on Quetiapine 100 mg/ day for mood symptoms. She was noted to have memory problems and experiencing significant problems at home. MOCA score was 16 out of 30. She underwent clinical psychological assessment of neuropsychological status with evidence of moderate to severe cognitive impairment affecting all cognitive domains tested. Although patient had prior diagnosis of Bipolar disorder, patient's childlike behavior was better characterized by a neurocognitive dysfunction. For this reason, Seroquel was discontinued. Patient's mood and psychotic symptoms were well controlled and patient appeared to be at her baseline. She was referred for further psychological testing and MRI Brain. Discussion: Although neurocognitive disorders mostly present with significant cognitive decline

from a previous levels of performance in one or more cognitive domains namely learning and memory, language, executive function, complex attention, perceptual-motor and social cognition; one needs to be aware that these patients with neurocognitive dysfunction may present with prominent mood symptoms. A timely diagnosis can lead to opportunities for early intervention, better management of symptoms and patient safety. Conclusion: Physicians needs to be aware that patients with neurocognitive dysfunction may present with prominent mood symptoms.

No. 116

A Comparative Study of Photoplethysmography on Alzheimer's Dementia With Severe Depression and Without Depression

Poster Presenter: Dongwon Shin

SUMMARY:

Background: Heart rate variability (HRV) is fluctuation of the heart beat interval and is controlled by the autonomic nervous system (ANS). The frequency and time domain parameters of HRV are calculated and used to understand the autonomic condition. The severity of depressive symptoms has been correlated with a reduction in parasympathetic activity. Patients with Alzheimer's dementia (AD) and mild-to-severe cognitive dysfunction show subtle, absolute, and relative parasympathetic reduction and relative sympathetic exacerbation. However, no study has examined AD with comorbid severe depression using HRV. Therefore, we investigated ANS function and its abnormalities in severe depressive disorder in AD.Methods:The study enrolled 90 outpatients who met the International Statistical Classification of Diseases and Health-related Problems, 10th revision (ICD-10) criteria for AD. Of these, 40 patients had AD with severe depressive disorder (ADwD) and were matched for age and gender with 50 patients with AD without depressive disorder (ADwoD). Severe depressive disorder was diagnosed according to the ICD-10 criteria. Magnetic resonance imaging of the AD patients showed widening of the choroid fissure and temporal horn of the lateral ventricle. Early stage AD was assessed with the Clinical Dementia Rating Scale and Scale for Medial Temporal Lobe Atrophy. ANS was evaluated using HRV, measured with photoplethysmography. Frequency domain measures were obtained at low (LF) and high (HF) frequencies, and included the LF/HF ratio. Time domain measures were obtained from the standard deviation of normal to normal intervals (SDNN) and the root mean square of successive differences in the NN interval (RMSSD). Student's t-test was used to compare groups. Statistical significance was set at $p<0.05$. Results:In the frequency domain, LF and HF were significantly lower in ADwD ($p<0.001$) and the LF/HF ratio was significantly higher than in ADwoD ($p<0.001$). In the time domain, SDNN and RMSSD were significantly lower in ADwD than in ADwoD ($p<0.05$). The frequency and time domain parameters of HRV were significantly lower in ADwD than in ADwoD. Conclusions:HF and RMSSD indicate parasympathetic balance, the LF/HF ratio reflects sympathovagal balance, and SDNN reflects the complexity of heart rate fluctuations. In ADwD, HF, LF, and SDNN were reduced, while the LF/HF ratio was increased. Therefore, autonomic imbalance reflecting reduced parasympathetic activity relative to sympathetic activity was associated with ADwD. Compared with ADwoD, ADwD showed that the complexity of heart rate fluctuation is relatively impaired. The severity of depressive symptoms has been correlated with a reduction in parasympathetic activity. Therefore, severe depressive disorder may predispose patients with early AD to a heightened risk of cardiovascular disease. Physician should pay more attention for evaluation and treatment of ADwD.

Korsakoff's Syndrome in a Patient With Schizophrenia: Illustrative Case and Literature Review

Poster Presenter: Ivonne Torriente Crespo, M.D.
Co-Authors: Yara Moustafa, M.D., Ph.D., Syed Aktar Naqvi, M.D.

SUMMARY:

Background: Substance use disorder is the most frequent and clinically significant comorbidity in patients with schizophrenia. About 33.7% of people with Schizophrenia or Schizophreniform disorder have met the criteria for alcohol use disorder at some time during their lifetimes. Biological and psychological factors are hypothesized to contribute

to this high co-occurrence. The Wernicke-Korsakoff Syndrome (WKS) is one of the gravest consequences of alcoholism, and post mortem studies suggest that it occurs in 12.5% of dependent drinkers, versus 2% of the general population. Korsakoff's syndrome is the chronic and amnestic part, which generally but not always, follows untreated Wernicke's encephalopathy. The disorder usually develops after years of chronic alcohol abuse and nutritional thiamine deficiency. It is characterized by memory impairment, cognitive dysfunction, confabulations, and is commonly a post mortem diagnosis. Case description: 45-year-old Caucasian female with 4 years of college education, and past psychiatric history of schizophrenia and alcohol use disorder. She was admitted to the hospital after being found wandering, disorganized, with illogical speech and partially unclothed. She provided limited history at admission, but review of records revealed significant cognitive and functional deterioration over the past 5-8 years. On examination, she was confused, with poor insight into her condition and showed serious memory deficits, especially anterograde amnesia with inability to form and consolidate new memories, variable retrograde amnesia, and many fantastic confabulations. Neurological examination revealed: poor physical coordination, wide-based gait and abnormal sensations. Neuropsychological testing showed an above average level of premorbid functioning, with a significant decline (-25 points) in the Full scale IQ (FSIQ), a difference greater than expected or attributable to schizophrenia alone. Discussion: We reviewed the literature related with comorbid alcoholism, self-neglect and thiamine deficiencies in patients with schizophrenia and other psychiatric disorders. Our case and others reported in the literature highlight the importance of an opportune diagnosis of alcohol-related pathology in patients with psychiatric illness. The presentation emphasizes the possible effects of long-term alcohol use, specific risk factors for the development of WKS in patients suffering from a major psychiatric disease and the possible elements involved in its frequent under recognition and under diagnosis. Conclusions: Early diagnosis and treatment of WKS have the potential to significantly reduce the memory loss and associated symptoms and to prevent further neurological deterioration that impact the level of global functioning and autonomy. It is crucial to increase the awareness of the problem, to improve the screening methods, to enhance the assessments protocols and instruments and to develop clear treatment recommendations.

No. 118

Frontotemporal Dementia: Latest Evidence and Clinical Implications

Poster Presenter: Juan Joseph Young, M.D.
Co-Authors: Silpa Balachandran, M.D., Krupa Pathak, M.D., Fnu Syeda Arshiya Farheen, M.B.B.S., Jason Patel, Rajesh R. Tampi, M.D., M.S.

SUMMARY:
Introduction: Frontotemporal dementia (FTD) describes a cluster of neurocognitive syndromes that present with impairment of executive functioning, changes in behavior, and a decrease in language proficiency. FTD is the second most common form of dementia in those younger than 65 years old and is expected to increase in prevalence as the population ages. Methods: Pubmed was searched to obtain reviews and studies that pertain to advancements in genetics, neurobiology, neuroimaging, classification, and treatment of FTD syndromes. Articles were chosen with a predilection to more recent preclinical/clinical trials and systematic reviews. Results: Recent reviews and trials indicate a significant advancement in the understanding of molecular and neurobiological clinical correlates to variants of FTD. Genetic and histopathologic markers have only recently been discovered in the past decade. Current therapeutic modalities are limited, with most studies reporting improvement in symptoms with non-pharmacological interventions. However, a small number of studies have reported improvement of behavioral symptoms with SSRI treatment. Stimulants may help with disinhibition, apathy, and risk-taking behavior. Memantine and cholinesterase inhibitors have not demonstrated efficacy in ameliorating FTD symptoms. Antipsychotics have been used to treat agitation and psychosis, but safety concerns and side effect profiles limit utilization in the general FTD population. Nevertheless, recent breakthroughs in the understanding of FTD pathology have led to developments in pharmacological interventions that focus on producing treatments with autoimmune, genetic, and molecular targets. Conclusion: FTD is an

under-diagnosed group of neurological syndromes comprising of multiple variants with distinct neurobiological profiles and presentations. Recent advances suggest there is an array of potential novel therapeutic targets, although data concerning their effectiveness is still preliminary or preclinical. Further studies are required to develop pharmacological interventions, as there are currently no FDA-approved treatments to manage FTD syndromes.

No. 119

Persistent Delirium Can Disguise as Dementia After a Mild Traumatic Brain Injury: A Case Report and Literature Review

Poster Presenter: Ahmed Eid Elaghoury, M.D.
Co-Author: Amany Ragab, M.D.

SUMMARY:

Background: For decades, delirium was considered as a short-term medical event, and it was rarely deemed to exceed one month according to the DSM-III. Recently, this tradition has repeatedly been examined and currently "persistent delirium" that lasts for weeks or months is described in the *DSM-5*. In that case, the distinction between persistent delirium and dementia is a difficult clinical situation. **Methods:** Current report describes a seventy-one years old senior man presented with rapidly impaired activities of daily living (ADL) along the previous four months after a mild traumatic brain injury (TBI). A literature review is done for "persistent delirium" or after a TBI using "Clinicalkey" and "PubMed" databases. **Results:** The impaired ADL described were regained three days after receiving haloperidol 0.75mg once daily prescribed for worsened agitated behaviors and increased level of arousal at night, "sundowning." Only advanced age was identified as a risk factor for persistent delirium in the current patient, without recognized previous TBI or chronic medical conditions. A recent systematic review (age ≥ 50 years, N=1,322 patients with delirium) estimated persistent delirium at discharge to be 21% after six months. Posttraumatic delirium is described in the literature since the 1930s, along with other descriptive terms, persisting for a duration not corresponding to the initial severity of TBI. **Conclusion:** Mild TBI can induce persistent delirium. In that case, diurnal variation of the level of arousal along the day (sundowning) may be utilized to clinically distinguish between persistent delirium and dementia, especially in patients presented with rapid impairment of ADL.

No. 120

Partial Fetal Alcohol Syndrome in an Adult: A Diagnostic Challenge in a Soldier With Severe Impulsivity and Hallucinations

Poster Presenter: Courtney E. Kandler, M.D.
Co-Author: Rohul Amin, M.D.

SUMMARY:

Background: Fetal Alcohol Spectrum Disorder is a term used to describe a group of specific conditions that can occur in an individual with prenatal alcohol exposure. Comorbid psychiatric disorders are common and can include conduct disorder, oppositional defiant disorder, anxiety, adjustment disorder, depression, sleep disorder, substance use disorder, and psychosis. Case: We present the case of an 18 year-old US Army Soldier whose clinical picture over the course of seven months in the military behavioral health system proved a diagnostic challenge. His initial contact with behavioral health was following a suicide attempt. He overdosed on acetaminophen and ondansetron requiring intensive level care. He also presented with depressed mood and reported command auditory hallucinations daily since he was nine years old. He was eventually discharged with a DSM-5 diagnosis of Psychosis, Unspecified and Mood Disorder, Unspecified. Over the course of his care, his clinical picture became striking for persistent reported command auditory hallucinations though he acknowledged those were not real and reality testing was intact. He was also very impulsive, reported difficulty with concentration and attention, and physically demonstrated dysmorphic facial features. He was referred to a Geneticist and diagnosed with partial Fetal Alcohol Syndrome (pFAS). In the context of persistent behavioral issues stemming from co-morbid diagnoses of disruptive, impulse control and conduct disorder, as well as an extensive history of substance abuse, he was medically discharged from the Army. Conclusion: The diagnosis of pFAS requires high clinical suspicion and diagnosis is often delayed. Psychiatrists need to

consider a broader differential, including pFAS when wide-ranging symptoms are seen without clear DSM-5 conditions as a unifying diagnosis. Early diagnosis informs expectations of response to treatment given patients with neurodevelopmental conditions can have varying (minimal) response to psychotropics. Using this case as a clinical vignette, we aim to provide an overview of pFAS in adults to educate our peers.

No. 121

Development of an Instrument for the Assessment of Perceptions, Attitudes, and Behaviors That Favor Reconciliation in the Colombian Population

Poster Presenter: Lina Maria Gonzalez, M.D.
Co-Author: Juan Cotte

SUMMARY:
Background: The effects of the Colombian armed conflict on the general population need to be assessed, and interventions that favor reconciliation must be designed and evaluated. Considering this, in association with USAID and ACDIVOCA, as part of the Program of Alliances for Reconciliation, our organization developed an instrument that aims to assess changes in perceptions, attitudes and behaviors toward reconciliation, to be applied in adults, of any educational level, and a variety of social contexts. Methods: Search terms were determined using the MeSH and APA dictionaries, to obtain appropriate definitions for the categories of perceptions, attitudes and behaviors, and 18 subcategories, relating to the categories were defined. Using these terms, a systematic review of psychometric tests was performed using APA-PsycTests. The search results were reviewed by two independent evaluators, and selection discrepancies were revised by an expert. Inclusion criteria for the tests were defined as follows: (i) availability of the scale in English or Spanish; (ii) the construct or the purpose of the scale relates to the categories or subcategories of the search; (iii) the scale is applicable in an adult population with a low educational level; (iv) the scale can be self-completed. Exclusion criteria were (i) the scale uses audiovisual aids, (ii) no report of validation or psychometric properties, and (iii) the instrument is use to validate a construct. The final selection of scales was presented to a panel of eight experts in topics of reconciliation with a multidisciplinary background. This panel reviewed each individual item from the scales, to judge if they considered the item was appropriate to evaluate a perception, attitude or behavior toward reconciliation, and to assess the language of the item and propose an adjusted version. Results: The search yielded 234 results, and another 8 tests were added by experts' suggestion, for a total of 242 scales. The review by the independent evaluators and the revision by the expert, left a selection of 11 tests. These were presented to the expert panel, which selected items from 6 scales. Only items that were considered appropriate by 5 or more experts were considered for selection, and using feedback from the experts, the language of each individual item was adjusted. This process ended with a 20-item instrument. Following recommendations from psychometry experts a 5-point scale was defined to grade each item, and for a preliminary grading system 12 subjects were asked to rank the items in order of importance. The results of an ongoing pilot study will be used to validate the instrument, and test its accuracy. Conclusions: Multiple interventions have been proposed to promote reconciliation, but there are no instruments available to measure their efficacy. Here we propose a novel instrument design approach that can be used before and after the interventions to assess their effect on the target populations.

No. 122

Assessment of the Efficacy of Writing and Memory Workshops Improving Cognition and Life Satisfaction

Poster Presenter: Juan Cotte

SUMMARY:
Background: During the 21st century, for the first time in history there is going to be more people over 60 years than people under 15 years of age, and this will not happen without consequences. Cognitive impairment is more common as people age, and in association with neurologic diseases, it has been identified as major cause of disability worldwide. This highlights the importance of cognitive interventions that positively impact cognitive, physical, and social functioning and quality of life, of the old adults. Methods: A quasi-experimental

design was performed to assess the effect of writing and memory workshops on life satisfaction and cognitive function in subjects over 60 years of age from three Colombian municipalities. Quantitative and qualitative methods were employed. Cognitive function was measured using the Montreal Cognitive Assessment (MoCA). Then the narrative formation strategy for the elderly, Historias en Yo Mayor (Stories in I Major) was applied to all of the study subjects. The strategy consisted of 26 weeks of 2 hour workshops divided in: (i) theoretical component in which participants were given tools to improve their story-telling ability, (ii) practical component in which the participants told their stories using oral and written narrative to their peers in the workshop, and (iii) sustainability component, focused on developing mechanisms to establish the workshops as a long-term activity in the community. Cognitive function was reassessed halfway through, and at the end of the workshops. The qualitative component consisted of focus groups to assess the satisfaction of the participants with the workshops. Results: The study population consisted of 40 subjects, residents from the departments Antioquia and Quindio in Colombia. 62.5% of the subjects were residents from urban areas. The mean age of the population was 70 years (SD 8.3 years). Also, 7.5% of the study participants did not have any academic studies, and 30% had college or superior studies. As for changes in cognitive function, there was a tendency to improve language, assessed by saying words starting with the same letter in a one minute span. At baseline 60% of the subjects were able to say more than 11 words, halfway 67% and at the end 70%. No clear tendencies were evidenced for the other components of cognitive function. Regarding the qualitative component most of the subjects reported being satisfied with the workshops and highlighted that this kind of activities helped them establish relations with other members of their community. Conclusions: There is a need for intervention that help the elderly members of society preserve their cognitive function. Writing and memory workshops, may slow the decline of cognitive function, particularly the language component, and generate networks for the people inside their communities. Further, controlled research, with longer follow-up should be performed to assess the long-term benefits of this interventions.

No. 123

The Debbie Project: A Service-Based Learning Program Aimed at Reducing Biases Among Medical Students Toward Individuals With Disabilities

Poster Presenter: Eric Gibbs
Co-Author: Gabrielle Hodgins

SUMMARY:
Background: The Debbie Project (DP) was established largely to address a lack of training with persons with intellectual and developmental disabilities (IDD). The purpose of the study was to assess perceptions in medical students before and after their participation in a volunteer program. Methods: Each medical student was assigned to a preschool classroom of children with IDD that they attended weekly during the 2016-17 school year. Perceptions of medical student volunteers were measured by administering the Multidimensional Attitude Scale Toward Persons with Disabilities (MAS). The MAS is a 34-item self-report questionnaire. Each item on the MAS is based on a 5-point scale, ranging from 1 to 5. The survey was done in an anonymous online format. Results: There were baseline sex differences in the data. On feeling helpless, females reported higher baseline scores. On fear, males reported higher baseline scores. On guilt, females reported higher baseline scores. Having a family member with disabilities resulted in significant differences on the pre-volunteering survey on stress and depression. Six questions showed a statistically significant improvement in score after volunteering. These were relaxation, serenity, calmness, pity, alertness, and finding an excuse to leave. Notably, there were no statistically significant changes that represented a worsened attitude towards persons with disabilities after volunteering. The total score improvement was also significant. Conclusion: Many studies endorse the idea that exposure to developmentally different patients helps to eliminate bias and discomfort of physicians. Further research is warranted to assess how medical education can best train future doctors to work with this special patient population. Significance: Upon analyzing the data it is clear that volunteering with developmentally different

preschoolers has numerous positive effects on the attitudes of medical students towards persons with disabilities.

No. 124

The Development of Protocol for Disaster Assistance Center of Korea Through a Delphi Method

Poster Presenter: Ho-Kyoung Yoon
Co-Authors: Young-Hoon Ko, Jae-Hon Lee, M.D., Ph.D.

SUMMARY:

Background: Disasters are often overwhelming and sudden in the form of natural disaster, terrorism, and large-scale accident, and experienced by a mass of people. The nature of disasters can disrupt individuals and families as well as the community at the global level. In the Sewol ferry disaster with 304 victims, there was no protocol to prepare adequate psychosocial supports to the individuals who experienced the disaster directly or indirectly. As a result, psychological difficulties have been experienced not only by the person directly involved in the accident but also by the community members (1). The reason for this is that existing resources such as medical institutions, social welfare facilities, and public institutions are not properly integrated. To organize the resource management and reorganization plan of community resource, we presented detailed plans and models to be implemented in each community in each phase including prevention, preparation, response and recovery. Methods: The process of developing the protocol was conducted using the Delphi method. A surveys was conducted for experts consisting of psychiatrists, psychologists, social workers, and administrators. A questionnaire consisting of 10 different domains with blank space for free statement was circulated. The comments and answers were summarized and discussed at a meeting of the related members to agree the final contents of the protocol. Results: A total of 30 statements achieved consensus for inclusion. It was suggested that the role of the community in response to the disaster should be divided into four phases according to the characteristics of each stage. The agreed four phases are as follows. Phase 0 is the step to prepare for the usual situation before a disaster occurs. At this phase, each institution in the community prepare the disasters. Phase 1 includes psychological first aid performed in relief activities and health services activities immediately after the disaster. At this phase, information on psychosocial support is provided at each disaster site and stabilizing intervention is provided. And the organization that will direct the resource allocation is specified. Phase 2 refers to the initial mental health support service that is provided within 1 month and up to 3 months from the disaster. It supports the stabilization program, psychological evaluation, acute stress counseling and acute phase medical treatment in disaster scene, victim's home, and each institution. Phase 3 is to support mental health assistance services after three months of the disaster. The goal of this phase is to return the victims and related individuals to a community successfully. Conclusion: The Delphi expert consensus method allowed to build a new protocol in an area where there are incomplete evidence. This protocol is expected to be a model that will help the efficient allocation of resources in disaster in Korea.

No. 125

Impact of Trauma and Post-Migration Stressors on African Immigrants and Refugees in Sweden

Poster Presenter: Simon Yohannes

SUMMARY:

Background: 1 in 10 refugees have PTSD, and 1 in 20 have depression, but there is little understanding about the predictors of PTSD and depression in refugees and immigrants, and its association with sexually risky behavior. Methods: The study include semi-structured interviews using validated and reliable questionnaires with 420 African immigrants and refugees who were living in Sweden. The questionnaires included the Harvard Trauma Questionnaire, the Hopkins Checklist, and a modified version of the WHO sexual risk behavior questionnaire. Data analyses included chi squared analysis and Mann-Whitney U test. Results: Prevalence data showed condom use was low, but there was no relationship between PTSD and condom use [$X2 = 4.39$, $p = 0.11$]. There was no significant association between traumatic events and the number of regular [$t = 1.764$, $p = 0.08$] or casual

sexual partners [t = 0.904, p = 0.37], but there was a significant positive association between use of commercial sex workers and the number of traumatic events experienced [t = 2.39, p = 0.017]. Females who reported higher levels of depression also had a greater number of lifetime sexual partners [U=3844, p= 0.001], regular sexual partners [U=3771, p=0.002] and concurrent partners [X2 = 4.39, p = 0.027]. PTSD and depression were not significant predictors of sexual risk behavior for men. Conclusions: The development of interventions to improve adjustment after migration should include treatment of PTSD and depression due to the significant association with sexual risk behavior.

No. 126

Cultural Differences in the Expression of Depression and Suicidality: A Case Report

Poster Presenter: Zev J. Zingher, M.D.

SUMMARY:

The patient is a 36-year-old female from the country of Manyamar who was initially admitted to the emergency room following a suicide attempt via carbon monoxide poisoning and subsequent lactic acidosis. In the ER the patient was diagnosed with a NSTEMI and elevated Troponins due to Takotsubo cardiomyopathy, commonly known as "Broken Heart Syndrome." Following medical stabilization in the ER, the patient was transferred to the inpatient psychiatric unit. The patient was an architect in her home country and came to the United States 2 years prior to complete a masters degree in urban design. She successfully completed her masters degree at which point she began to seek employment. To her tremendous dismay, she was unable to get hired for any job following graduation from her master's program and was informed by U.S. immigration she would have to return to her home country of Manyamar. As result of this perceived "failure" to succeed finding work in America, the patient felt tremendous shame, that she had "lived long enough" and would commit suicide via carbon monoxide poisoning in her apartment which she implemented and was found unconscious by her roommate prior to admission. While working with the patient, it became clear that the patient's sense of shame and embarrassment drove her to attempt suicide. She did not present with the classic features of depression with anhedonia, difficulty sleeping, weight loss, etc., but rather felt that her cultural and familial identity in Manyamar was such that she could keep living as such a source of embarrassment. The patient would spend approximately 7 hours a day sitting on her bed meditating as she was Buddhist. She was started on a very low dose of an SSRI antidepressant, though she was hyper responsive to it and would not take the medicine following discharge. Of note, the patient consistently avoided speaking about any psychologically oriented topics and mental illness were "not discussed" in her country nor within and family. When asked if any family members suffered with mental illness, the patient said no, that such issues are not spoken about in her culture. From a psychological/biological perspective, it is interesting to reflect on how the patient's refusal to express her emotional life directly was instead expressed somatically, in part, through her development of Takotsubo cardiomyopathy and its connection to cardiac dilation following severely stressful and traumatic experiences leading to noradrenaline release and cardiac tissue damage. Importantly, this case report also illustrates the importance of American psychiatrists to remain cognizant of the way cultural differences often motivate immigrant patients to depression and potentially even to suicide.

No. 127

First-Episode Auditory Hallucinosis in a 66-Year-Old Patient as an Initial Symptom of Brain Change

Poster Presenter: Zev J. Zingher, M.D.

SUMMARY:

The patient is a 66 year old African American female with no past psychiatric history who was brought to the ED by her son due to auditory hallucinations for the last one year telling the patient to pack up and leave the house she has inhabited for the last 30 years. The patient is psychiatrically notable for her positive affect, articulate speech, goal-directed, logical thought process and sense of humor in juxtaposition to her conviction that the male and female voices of, as she says, "real people I cannot see" have been telling her to leave her house. Medically, the patient reports that she went on a diet about 1 year ago in which she ate only 1 meal per day and subsequently lost fifty pounds. She

denied the use of any diet or herbal supplements. She has no medical problems besides childhood asthma. The patient reports that the voices go away when she listens to music and for the most part, these voices do not interfere with her life (i.e. she continues to garden, visit her 86 year-old mother, read voraciously, exercise, etc.). She admits to bilateral tinnitus and intermittent palpitations when feeling anxious. Patient denied depression, panic attacks, SI/HI, VH, tactile hallucinations, difficulty sleeping, racing thoughts, hyperactivity, crying, headaches, vision changes, nausea, vomiting, numbness, or paresthesias. Her CBC was WNL, UDS was negative, UA was negative for acute infection. CT scan of the head was performed and showed no acute intracranial abnormalities. Additionally, she was examined by the neurology consult team for an organic explanation of her symptoms. They reported that she was neurologically clear. The patient is particularly interesting from a psychiatric and neurological perspective since she presents with command auditory hallucinations at a later age, and as she joked, "The neurology team didn't find a baseball sized tumor in my brain to explain my voices." She presents later in life with psychosis even in the context of the bimodal age distribution seen in schizophrenia. Prior to initiating psychopharmacologic treatment, the patient was administered a MOCA cognitive assessment, scoring a 26 out of 30 with construction deficits and mild short-term memory loss with a confabulated recall that possibly suggest early brain change. The patient was started on Abilify 5mg and released from acute inpatient care. While this was a very brief inpatient stay, this patient's presentation brings up interesting questions regarding auditory hallucinations without an apparent organic cause, though a MRI, if cost permitted, would have be helpful. Additionally, this case presents auditory hallucinosis in a moderately elderly patient as a potential early warning sign of brain change presenting as a psychiatric malady.

Modern Slavery: Human Trafficking, the Mental Health Consequences, and Louisiana's Response

Poster Presenter: Shawn E. McNeil, M.D.
Co-Authors: Astik Joshi, M.D., Mark Cogburn, D.N.P., Ph.D.

SUMMARY:
Human Trafficking Is the second most profitable transnational crime and it generates $150 billion annually. This activity can include trafficking for sex, labor, or even organs. This is a crime that affects young people disproportionately. Youth are at a greater risk if they have, faced prior abuse, escaped civil conflict, lost their homes, fled broken child protection systems, or lack strong social support systems. Aside from the 13th amendment which protects against involuntary servitude (except as punishment for a crime), there are several laws and statutes that address human trafficking on a state-to-state basis. In Louisiana, LA Revised Statue 14:46.2 both defines the activity and prescribes punishment for those involved in committing this crime. 88% of trafficked young people saw a medical provider during their time being trafficked. So, it is important to know the signs. Additionally, these patients often present in the mental health setting with specific disorders including depression, anxiety, nightmares, substance abuse, overdoses, and suicide attempts. In treating these patients, it is important to use a trauma-informed approach which involves assessing for signs of stress while interacting with the patient to avoid retraumatization. Finally, the scope of the human trafficking problem in Louisiana is detailed. Additionally, resources available in the state are outlined to illustrate the approach this state has taken to address this problem.

No. 129

The Role of Vitamin B6 Deficiency in Neuropsychiatry

Poster Presenter: Shawn E. McNeil, M.D.
Co-Authors: Astik Joshi, M.D., Anuj Shukla, M.D., Miky Kaushal, M.D., Lee Stevens, M.D., Sarfraz A. Mohamed

SUMMARY:
Vitamin B6 (including pyridoxine, pyridoxamine and pyridoxal) is a water-soluble vitamin which is essential for metabolism in humans. Although deficiency of this vitamin is rare, clinicians should recognize its symptoms which may be severe. Vitamin B6 is a cofactor in several metabolic pathways including the tryptophan-serotonin pathway. There are several proposed neuropsychiatric manifestations of vitamin B6

deficiency. Vitamin B6 has been associated with serotonin or catecholamine deficiency. A previous study has established the link between low B6 levels and depression in outpatients. A "significant association" was found between PLP (pyridoxal 5'-phosphate, a B6 derivative) and depressive symptoms. Research on the role of vitamin B6 on cognition is limited. Overall, longitudinal analyses have found that insufficient vitamin B6 correlated with cognitive decline and Alzheimer's disease in older adults, while other B vitamins have not shown the same effect. Further investigation has revealed the role of vitamin B6 on homocysteine levels. High blood levels of the amino acid homocysteine have been shown to correlate with increased risk of Alzheimer's disease. The presence of pyridoxal-5-phosphate, is noted as a marker for cognitive decline. B vitamins have been advanced as a preventive for insomnia based on research that suggests deficiencies in vitamin B6 promote psychological distress and ensuing sleep disturbance. However, doses of B6 over 100 mg have been known to be toxic and cause night restlessness, vivid/lucid dreams over a prolonged use period. There was a tendency for vitamin users to have a greater number of awakenings during the night, a greater total wake time during the night, greater use of sleep medications, and a higher rate of insomnia than non-users. Vitamin B6 is important in the development and functioning of the human brain. B vitamin levels can be affected by a variety of factors including age and genetics. In fact, genetic polymorphisms may complicate the direct relationship between B vitamin deficiency and potential symptoms. Genetic factors regulate biochemical pathways that use B vitamins as cofactors (for example, homocysteine is broken down to the antioxidant glutathione with B6 as a cofactor). Vitamin B6 is involved in the synthesis of several neurotransmitters including serotonin, dopamine, norepinephrine, epinephrine, and GABA. Because it raises the concentrations of serotonin and dopamine, it can improve symptoms of depression which in turn also improves sleep. B6 is also involved in the synthesis of melatonin via serotonin. Thus, it can improve the quality of sleep and preserve the circadian rhythm. B6 may lower the risk for Alzheimer's disease by lowering serum homocysteine levels.

No. 130

Cognitive Deficits and Metabolic Parameters in Veterans

Poster Presenter: Ali Najafian Jazi, M.D., M.S.
Co-Author: Mamta Sapra, M.D.

SUMMARY:

Background: Cognitive disorders in men may precipitate weight loss, with eventual propensity to malnutrition(1). Such metabolic changes are expected to stem from the patient functional dependence, and therefore influenced by the level of caregiver commitment. The objective of our study is to assess the relationship between severity of cognitive dysfunction and body weight, body composition, general markers of circulation and nutrition in a Veterans population at the Salem V. A. Medical Center. Methods: 53 patients participated in an ongoing cross-sectional study in Memory Disorder Clinic at Salem VA Medical Center. We obtained demographic data, Montreal Cognitive Assessment score(MOCAs), systolic blood pressure (SBP), diastolic blood pressure (DBP), mean arterial blood pressure (MAB), body mass index (BMI), waist circumference (WC), waist-hip-ratio (WHR), and waist-height-ratio (WH). Additionally, in order to assess possible effect from metabolic and nutritional status we collected available data for lipid profile (total cholesterol, high density lipoproteins (HDL), and triglycerides (TG)), thyroid stimulating hormone (TSH), and albumin level. Results: Using regression analysis we studied the correlation between MOCAs vs. age, SBP, DBP, MAB, BMI, WC, WHR, WH, albumin, total cholesterol, HDL, TG, and TSH. The study found significant correlation between BMI and MOCAs ($r=0.32$, $p=0.023$). Additionally, we analyzed the relationship between BMI and all variables except MOCAs. Results showed significant relationship between BMI vs. WC ($r=0.9$, $p<0.00005$), WHR ($r=0.62$, $p<0.00005$), WH ($r=0.89$, $p<0.00001$), TG ($r=0.296$, $p=0.03$), HDL ($r=0.33$, $p=0.015$), and age ($r=-0.45$,$p=0.0007$).There was also a positive but insignificant correlation between DBP and BMI ($r=0.27$, $p=0.051$). Conclusion: Decreased body weight as a correlate of cognitive impairment in the Veterans at Salem VAMC is not found to be associated with malnutrition and circulatory compromise. The latter is possibly attributed to the

level of care offered to this patient population. Strong correlation of BMI, but not cognitive scores with markers of abdominal fat redistribution indicate cognitive-independent role of total body fat as the underlying mechanism for abdominal obesity and its metabolic adversities. The results in this study warrant more elaborate prospective trials in the future.

No. 131

Amyotrophic Lateral Sclerosis and Late Life Depression: A Case Report

Poster Presenter: Arushi Kapoor, M.D., M.Sc.
Co-Author: Sarah Anne Kleinfeld, M.D.

SUMMARY:

Amyotrophic lateral sclerosis (ALS), commonly known as Lou Gehrig's disease, is a progressive, idiopathic, and chronic neurodegenerative disease. Upper and lower motor neurons responsible for voluntary muscle control are typically affecfted. This neural degeneration causes spastic paralysis and muscle dystrophy which results in disability and ultimately death, typically within 2-5 years after diagnosis. The national prevalence of ALS in 2011 was 3.9 per 100,000. White males, non-Hispanics and those between the ages of 60-69 years are the most frequently affected populations. ALS is a progressive disease associated with multiple complications including respiratory insufficiency, sialorrhea, pseudobulbar affect, sleep disruption, spasticity, fatigue, laryngospasm, autonomic symptoms, pain, and depression. Depression is a common neuropsychiatric complication of ALS. Estimated prevalences range from 6% for severe depression and 16.2-29% for mild depression. Depression may be difficult to diagnose and treat given confounding factors related to the progressive nature of the primary disease. For example, mood symptoms may be difficult to separate from disease specific physical symptoms such as fatigue and weakness. Additionally, given the progressive nature of ALS, ongoing decline in physical functioning may make mood symptoms refractory to treatment. Several new disease specific rating scales, including the ALS Depression-Inventory, exist to aid clinicians with appropriate diagnosis and help guide treatment. We present a case of an elderly man diagnosed with ALS who subsequently developed depressive symptoms in the context of his neurodegenerative disease and transition to a nursing home after experiencing a fall at home rendering him unable to independently care for himself. As with many ALS patients, his physical decline and debilitation contributed significantly to the development of depressive symptoms. He also had difficulty accepting his need for a higher level of care. Our patient ultimately experienced remittance of his depressive symptoms after treatment with an SSRI. In addition to highlighting pertinent aspects of this case, our poster will present a literature review discussing the evaluation, diagnosis, and treatment of patients with ALS and co-morbid major depressive disorder.

No. 132

New-Onset Psychosis in a Patient With Parkinson's Disease and Major Depressive Disorder

Poster Presenter: Brittany Mott, M.D.

SUMMARY:

Patient is 63-year-old Caucasian man with history of Parkinson's Disease and Major Depressive Disorder, who presented to the inpatient geriatric psychiatry unit for the treatment of worsening depression and presumed catatonia. He was transferred from a medical unit after he was treated and stabilized for failure to thrive. He has a history of multiple depressive episodes, however, no previous psychiatric inpatient admissions, no significant substance abuse history, and no history of psychosis or mania. Upon initial assessment, he endorsed three months of: amotivation, anhedonia, and apathy following the death of his father, which resulted in inadequate self-care, >40 pound weight loss, decubitus ulcerations, and non-adherence to medications (including Carbidopa-Levadopa). Physical exam revealed rigidity, with no evidence of other catatonic symptoms. His mental status examination was significant for a dysphoric affect with poor insight into the severity of his symptoms. His Carbidopa-Levadopa was restarted, and bupropion and quetiapine were initiated for mood stabilization. Within a few days, he became increasingly: guarded, suspicious, and paranoid, with no identifiable acute medical processes to explain the behaviors. Quetiapine was not effective in alleviating the psychotic symptoms and higher doses

resulted in over sedation, so it was discontinued and risperidone was started which further worsened his psychosis. Neurology was consulted to assist in the management of Carbidopa-Levadopa dosing, and observed that the patient experienced marked worsening of hallucinations and delusions at higher doses. Their assessment stated that the onset of this degree of drug induced psychosis within 3-4 years of motor symptom onset suggested a strong possibility of Diffuse Lewy Body Disease. Through collaborative care discussions, the patient was started on clozapine in order to minimize extrapyramidal symptoms while ensuring adequate treatment of psychosis while he resumed Carbidopa-Levadopa. In this poster, we discuss the challenges of mood stabilization and finding the dopaminergic balance with antipsychotic and Carbidopa-Levadopa treatments in a patient who suffers from a neurodegenerative disease, in addition to the importance of a collaborative care approach with thorough discharge planning in this multifactorial case.

No. 133

The Effect of Depression on Serum Amyloid-Beta Protein in Alzheimer's Disease and the Elderly Without Dementia

Poster Presenter: Dohoon Kim

SUMMARY:

Background: This study first explored whether serum amyloid-beta peptides (amyloid-beta 40, amyloid-beta 42 levels, and amyloid-beta 40/42 ratio) are different by the presence or absence of depression in Alzheimer's disease group and in the elderly without dementia group through collinear observations. The study also examined alteration of serum levels after depression treatment in AD patients with depression and the elderly with late-life depression. Methods: Serum peptides amyloid-beta levels were measured in 24 AD patients with depression (AD + D), 27 AD patients without depression (AD – D), 16 late-life depression (LLD), and 13 healthy controls using solid phase sandwich ELISA assay kit. The patients were treated according to their diagnosis for 16 weeks. All outcomes were assessed at baseline and at endpoint. Comparisons of differences in amyloid-beta 40, amyloid-beta 42 levels and amyloid-beta 42/40 ratio between groups were done using the independent sample t-tests, and Mann-Whitney U-test when the data were not normally distributed. Paired t-tests were used for comparisons of before and after treatment. Results: There were no differences in serum amyloid-beta 40, amyloid-beta 42 levels, and amyloid-beta 40/42 ratio between AD + D and AD - D, and serum amyloid-beta levels were unchanged after depression treatment in AD + D. In contrast, LLD had lower serum amyloid-beta 42 levels than HC. After depression treatment, LLD showed a significant rise in serum amyloid-beta 42 levels and a decrease in amyloid-beta 40/42 ratio between pre- and post-treatment. Improvement in executive function in LLD was associated with enhanced serum amyloid-beta 42 levels. At 16 weeks, AD – D showed increased serum amyloid-beta 42 levels and decreased amyloid-beta 40/42 ratio. Conclusion: From results of this current study, it could be speculated that serum amyloid-beta levels might not be affected by depression even though depression is superimposed to AD. In LLD, however, depression might play a role in reducing serum amyloid-beta 42 level. Accordingly, this study suggests that pathophysiology of depression in AD may differ from LLD.

No. 134

Effective Use of the Interstate Compact: A Case of a 69-Year-Old Male With Mental Illness Who Wandered Off

Poster Presenter: Lionel E. Znaty, M.D.
Co-Author: Raj V. Addepalli, M.D.

SUMMARY:

Mr. W is a 69 year old Caucasian male with a past psychiatric history of schizophrenia arrived to the psychiatric emergency services in handcuffs, hurling racial slurs to everyone, threatening and menacing. Upon first evaluation in the inpatient unit, patient endorsed several delusional thoughts including "having the cure for herpes, AIDS, malaria and sleeping sickness". He was evaluated and started on risperdone, which was titrated to 2 milligrams twice daily and sodium valproate 250 milligrams twice daily, which was titrated to 500 milligrams twice daily. Sodium valproate was subsequently discontinued as patient complaining of severe sedation and his ammonia levels were found to be increased to 65mg/dL. Patient was found to have a

high TSH and history of untreated hypothyroidism for years. Patient constantly refused Levothyroxine during the admission. Patient's case manager was eventually located and corroborated with history obtained. As per case manager patient is a Vietnam War veteran who was diagnosed with schizophrenia for more than thirty years and was on Haloperidol decanoate for years. Patient reportedly had an IQ of 130 and has a diagnosis of PTSD after a male soldier opened fire inside the patient's tent, killing his comrades but sparing his life. In addition, after the patient was discharged, he was physically assaulted by a group of males, and "retaliated with flashbangs and opened fire." Patient continued to be delusional and not agreeing to switch in antipsychotics and refused a trial of clozapine. Patient refused a CT scan and serum risperidone levels. This article reflects on the difficulties in medication compliance and success of treatment in the geriatric psychiatry population. The local VA hospital was contacted and did not agree for an inter-hospital transfer, as patient has not been connected to the VA for 24 months. Previous treatment providers in Pennsylvania were contacted and the local state hospital in Pennsylvania agreed to the interstate transfer. This case highlights the importance of the interstate compact on mental health, which was initiated in 1956 which ensure that the proper treatment of persons with mental conditions and mental disabilities can be facilitated by cooperative action to the benefit of the patients between state hospitals and the long process involved in transfer of patients back to their home state. This case also highlights the difficulty in connecting patients back to the community when patients of mental illness tend to wander off and travel to other states when they decompensate.

No. 135

Second-Generation Antipsychotic Use in Patients With Dementia and Comorbid PTSD: A Case Report and Literature Review

Poster Presenter: Lisa T. Do, D.O.

SUMMARY:

Background: Second generation antipsychotics (SGAs) are often prescribed off-label to individuals with PTSD and/or dementia, typically to address symptoms such as insomnia and agitation. There is significant literature reporting increased risk of stroke and all cause mortality in dementia patients taking SGAs. Limited research has been done regarding the use of SGAs to treat PTSD in patients with comorbid dementia or mild cognitive impairment. **Case:** We present the case of a patient whose dementia-related behavioral agitation and PTSD symptoms were well treated with risperidone. Additionally, we present a literature review regarding the use of SGAs to treat PTSD in dementia patients. Mr. J. is a ninety year-old man with a past psychiatric history of vascular dementia and chronic PTSD (related to his time as a WWII prisoner of war). His medical history is significant for hypertension and hyperlipidemia. He was recently admitted to a nursing home as his family was unable to care for him at home due to progression of his dementia. His last documented Folstein Mini-Mental Status Exam score was 18/30, consistent with moderate dementia. Shortly after admission, Mr. J. began displaying aggressive behaviors. He was seen swinging a clenched fist and threatening to kill another patient who had kicked him, and also believed that the staff tied him to his bed at night and tortured him. It was thought that these delusions were specifically associated with his PTSD and military history as a prisoner of war. When Mr. J. did not respond to behavioral interventions, geriatric psychiatry was consulted. His behaviors were initially stabilized on low dose quetiapine, but he began to decline again and refuse oral medications. Mr. J. was switched to orally disintegrating risperidone, which helped with both compliance and symptoms. After three months on risperidone, Mr. J. became less withdrawn. At time of last follow-up, he was noted to be enjoying visits from the chaplain as well as participating in groups and outings with his peers. He is no longer combative or experiencing persecutory delusions. **Conclusion:** There is limited literature regarding the use of SGAs to treat PTSD in dementia patients. It is generally recommended to avoid SGAs in this patient population due to increased risk of stroke and all cause mortality. However, limited other therapeutic options exist for behavioral symptoms in dementia patients when behavioral interventions are unsuccessful. We present a case of patient whose PTSD and behavioral symptoms were successfully treated with risperidone. It is important to weigh risks, benefits,

and potential side effects when considering initiation of SGA treatment in dementia patients.

No. 136

Does Dextromethorphan/Quinidine Improve Pseudobulbar Affect Symptoms in HIV-Associated Dementia Patients?

Poster Presenter: Mueen Ahmad, M.D.

SUMMARY:

Background: Pseudobulbar Affect (PBA) is associated with sudden outbursts of involuntary crying or laughing in patients with neurological disorders, without any sad or humorous event to trigger these emotional episodes. Previous research studies have demonstrated that PBA symptoms may improve with Dextromethorphan/Quinidine (DM/Q) treatment, which is the only FDA approved medication indicated for PBA symptoms in spite of the primary etiology of the symptoms. There is limited information regarding the prevalence of PBA symptoms in patients with HIV-associated Dementia (HAD) however, our previous research study conducted in the nursing home of Brookdale University Hospital Medical Center (BUHMC) showed a significantly high prevalence of 69%. To our knowledge, there is no previous study that assessed the improvement of PBA symptoms in HAD with DM/Q treatment. Objective: The primary aim of the study is to assess the efficacy of DM/Q on HAD patients who exhibited PBA symptoms. Methods: This IRB-approved, prospective study will monitor the improvement and progression of PBA symptoms of HAD patients who are on DM/Q as part of their treatment regimen using Center for Neurologic – Lability Scale (CNS-LS). The CNS-LS has been used as a measure of PBA symptom frequency and severity and has been validated in patients with ALS or MS. The CNS-LS does not confer a diagnosis of PBA, but rather suggests PBA symptoms that require further diagnostic evaluation. After informed consent will be obtained, the subjects that meet all the inclusion criteria will be included in the study. Data regarding demographic information, diagnosis, current medications, CNS-LS score before starting DM/Q (documented in the initial study), date of starting DM/Q, CNS-LS at 1 month, 3 months and respectively 6 months after starting the treatment will be collected. No personal information will be used and information will be entered in a password-protected Excel spreadsheet, accessed by the principal investigator and coordinators only. The data will be statistically analyzed to identify the difference in CNS-LS. Results: The study commenced in November 2016 and continues as we incorporate more patients from the initial study. Preliminary data suggests an improvement in CNS-LS scores by 6 months. In order to further validate the significance of the data, we will be adding more patients on DM/Q. The individuals who are found to have a 50% reduction in CNS – LS score will be considered responders and the individuals who are found to have less than 50% reduction in CNS-LS will be considered non-responders. This study will help the scientific community to better understand the effectiveness of DM/Q in HAD with PBA symptoms.

No. 137

First-Episode Psychosis in Immigrant Children and Its Management

Poster Presenter: Naeema Noor Hassan, M.D.
Co-Authors: Zohaib Majid, Asghar Hossain, M.D.

SUMMARY:

Childhood-onset psychosis is rare with insidious course and onset prior to the age of 12 years. The severity of positive and negative symptoms in acute episodes is predictors of significantly worse outcome. Often challenging to diagnose children present with a multitude of psychiatric disorders that may represent underlying depression, anxiety, posttraumatic states, and autism spectrum disorders or a secondary medical condition. The aim of this article is to report a rare case of first episode childhood psychosis in an immigrant and its management We present a case of a 12-year-old Asian male, who recently immigrated to the United States, brought in by EMS to Bergen Regional Medical Center emergency department for evaluation of progressively worsening visual and auditory hallucinations. According to his mother the patient had been “hearing voices and seeing an oval-shaped face with red eyes” appearing for the previous ten day. These visual hallucinations progressively worsened leading to a stark decline in school performance. As a result of his fear the patient would hide his head in his hoodie at school and home. No recent stressors were identified. The

school's counselor contacted the patient's mother recommending a psychiatric evaluation. The mother stated supernatural spirits possessed her son and only the power of prayer would heal him. He additionally experienced tactile hallucination stating, "someone was on top of me" resulting in feeling paralyzed and unable to talk for an hour. Due to the parent's cultural and religious beliefs, it became challenging to administer medication once a diagnosis was established. The patient was started on Risperdal 0.5 mg with good response. Review of literature has indicated childhood psychosis is part of a complex interaction between genetic, biological, psychological and social factors. There has been no definitive evidence suggesting superiority to the typical medication used in psychosis, however atypicals are preferred in children. Researchers have observed that schizophrenia is three times more frequent in immigrants than in native-born subjects. According to a study immigrants were at elevated risk for both non-affective and affective psychoses, but this varied by ethnicity.(7) In conclusion, we have observed a rare case of childhood psychosis and illustrated the importance of ruling out medical and psychiatric conditions before establishing a definitive diagnosis. The stress and hardship encountered particularly in first generation migrants reportedly predisposed them to a higher risk of mental ill health compared to the settled population. The dramatic change in environment especially in a developing child can have severe negative impact short and long term. In our observation, although it is established that childhood onset psychosis has a poor prognosis and requires a higher level of care to establish better long-term outcomes for children and adolescents.

No. 138

A Case of Cerebellar Ataxia Secondary to Lithium Toxicity

Poster Presenter: Naeema Noor Hassan, M.D.
Co-Authors: Javeria Sahib Din, Asghar Hossain, M.D.

SUMMARY:

Introduction Cerebellar ataxia is an injury to the cerebellum which commonly results in uncoordinated movements, altered mental status, nystagmus, dysarthria, tremor and proximal muscle weakness. One of the reasons of cerebellar ataxia is toxicity of lithium in patients who are taking it. Objective We are reporting a case of cerebellar ataxia induced by lithium toxicity. The objective is to highlight the neurophysiology of the changes involved in the brain secondary to lithium toxicity and their management by buspirone. Case "AA'' is a 68 years old, divorced, retired Caucasian female with a history of bipolar disorder and multiple medical problems i.e., hypertension, glaucoma, and depression. Patient has passive suicidal ideations and poor activities of daily living (ADLs). She smokes 1 to 1-1/2 pack cigarettes per day. The patient once set a fire in her apartment which caused smoke inhalation. Patient has no history of prior inpatient psychiatric hospitalizations. She has a history of lithium toxicity. Currently takes Xanax and Klonopin (0.5mg, BID). Patient has been followed by a psychiatrist and has no history of drug or alcohol abuse. Patient has no significant lab findings. On mental status examination, the patient appears older than her stated age, thin and emaciated. She has poor personal hygiene and appears disheveled. Patient has abnormal buccal, lingual and extremity movements. Gait is unsteady, speech is soft, slow, slurred at times, coherent and goal directed. Attention and concentration are poor. Alert, oriented to time, place and person. She appears anxious, depressed and withdrawn. Judgment and insight are limited. She has feelings of hopelessness and helplessness. Patient denies current suicidal or homicidal intent or plan. Patient scored 29 out of 30 on the mini mental status examination. Discussion Our case and reviewed literature indicate the association of cerebellar degeneration with lithium use. Neuropathological and histological destruction of Purkinje cells causes significant decrease concentration of 5-HT1A serotonin receptors. As a result, lithium toxicity is markedly improved by buspirone. Early detection of the signs of lithium toxicity is very important in terms of successful treatment and improvement of the quality of life in patients on lithium.

No. 139

Methadone and Buprenorphine Treatment in Pregnant Women and Its Effects on Neonates

Poster Presenter: Naeema Noor Hassan, M.D.
Co-Authors: Javeria Sahib Din, Asghar Hossain, M.D.

SUMMARY:
Background CDC reports an increase in the incidence rate of Neonatal abstinence syndrome(NAS) from 1.6 per 1000 to 6 per 1000 births from 1999 to 2013. It poses a financial burden on the health department. Methadone maintenance treatment is the preferred option for opioid dependent mothers during pregnancy. Some studies suggest buprenorphine should be the first line treatment during pregnancy. Methadone is an opioid receptor agonist and buprenorphine is a partial agonist at opioid receptor. Buprenorphine has less adherence for this receptor and hence has reduced effects of morphine. However, NAS from methadone requires prolonged hospitalization and treatment of the infant. NAS can cause effects on CNS, GIT, autonomic nervous system, respiratory symptoms etc. It can be hazardous if left untreated. These infants are irritable, have rigid muscle responses, high pitched cry, have a poor suck reflex and it is difficult to feed them. These symptoms can begin with 24 to 72 hours and last for 3 to 5 days approximately and sometimes for a longer duration. MDR1 gene has been associated with the severity of methadone withdrawal symptoms. Other factors such as tobacco exposure during pregnancy and breast milk also play a role in the severity of NAS symptoms. Objective The objective of this literature review is to highlight the effects of methadone and buprenorphine on neonates of addicted mothers. Pros and cons of both are discussed in detail. Method Literature from PubMed and Cochrane from the year 2000 onwards is reviewed. Results of the clinical trials comparing the two drugs are reviewed. Conclusion When buprenorphine is compared head to head with methadone in a clinical trial, treatment of NAS from methadone required a lesser amount of morphine, lesser days of stay in the hospital and lesser duration of treatment. However, results have been varied in previous studies. Buprenorphine has been superior in length and amount of treatment in RCT. In another study, methadone demonstrated more severe symptoms of NAS as compared to buprenorphine. More data is required to say with certainty which of these two drugs is superior to other for preventing or reducing NAS symptoms. It is an area of research.

No. 140

Comparing Buprenorphine and Methadone Treatment in Opioid Dependent Pregnant Women

Poster Presenter: Naeema Noor Hassan, M.D.
Co-Authors: Zohaib Majid, Asghar Hossain, M.D.

SUMMARY:
Background According to the CDC, drug overdose is the leading cause of accidental death in the United States, with 52,404 lethal drug overdoses in 2015, of those, 33,091 (63.1 percent) involved a prescription or illicit opioid.(1)The prevalence of opioid dependence during pregnancy increased from 0.17% (1998) to 0.39% (2011). (2)This epidemic has lead to higher rates of infection, premature delivery, and lower birth weights. Although methadone is the most commonly used treatment for opiate addiction during pregnancy it can have severe effects on the neonates from withdrawal, mainly neonatal abstinence syndrome (3). Methadone is a long-acting opioid primarily acting as a mu-receptor agonist, which crosses the placenta and may result in fetal dependence. Buprenorphine, a partial mu-opioid agonist and kappa-opioid antagonist, has low intrinsic receptor efficacy results in a less-than-maximal opioid effect and a diminished risk of overdose, as compared with methadone. CDC reported an increase in the incidence rate of Neonatal abstinence syndrome (NAS) from 1.6 per 1000 to 6 per 1000 births from 1999 to 2013. Studies have suggested buprenorphine should be the first line treatment during pregnancy (4). Objective The objective of this literature review is to compare Buprenorphine and Methadone treatment in opioid dependent pregnant women. Method Literature from PubMed, New England Journal of Medicine, American Journal of Obstetrics and Gynecology is reviewed. Conclusion Buprenorphine demonstrated advantages over methadone including a diminished risk of overdose, less abrupt withdrawal, and fewer drug interactions. In addition, buprenorphine may result in a reduction in the incidence and severity of neonatal abstinence syndrome when compared to methadone. (9) Studies demonstrated buprenorphine treatment during pregnancy was not associated with greater harms than methadone when compared. Additionally there has been moderately strong evidence indicating buprenorphine having lower risk of preterm birth, greater birth weight and larger head circumference.

(7). One study concluded maintenance therapy in an opioid-dependent mother with buprenorphine led to better outcomes when considering Neonatal Abstinence Syndrome and preterm birth while proving to be more cost effective compared to methadone.(8) It is difficult to definitively state with certainty whether buprenorphine is superior to methadone and further research is still required.

The Role of Estrogen Supplementation in Premenopausal Women to Prevent Alzheimer's Dementia

Poster Presenter: Naeema Noor Hassan, M.D.
Co-Authors: Zohaib Majid, Asghar Hossain, M.D.

SUMMARY:

BACKGROUND Alzheimer's disease (AD) disproportionally affects females and males The female predisposition has been associated with the loss of ovarian sex hormones when menopause is reached.(1) Endogenous and exogenous estrogen influences many of the structural and functional aspects of the AD brain. Autopsy of an AD brain revealed marked atrophy focused in the basal forebrain and medial temporal structures. There has been evidence suggesting that the reduction in estrogen during the menopausal transition plays a role in developing Alzheimer's dementia later in life. (2). Estrogen helps to promote growth of cholinergic neurons which has antioxidant properties and promotes the growth and survival of these neurons increasing cholinergic activity while additionally increasing the nonamyloidogenic metabolism of the amyloid precursor protein.(3) Despite controversies, estrogen replacement therapy, when given prior to menopause has been shown to reduce the risk of AD in postmenopausal women.(4) The critical window theory speculates that estrogen has the most beneficial and effect on neurocognition when taken only in the perimenopausal period. OBJECTIVE The objective of this literature review is to investigate the role of estrogen supplementation in menopausal women to prevent Alzheimer's dementia Method: Literature from Pubmed, Google, and Wiley Online Library is reviewed Conclusion According to one study estrogens has an effect on brain tissues and processes in ways that might improve Alzheimer symptoms or may reduce the risk of developing Alzheimer's disease.(6) An observational longitudinal study compared the use of hormone therapy in both mid-life and late-life risk of dementia found that women using hormone therapy in mid-life (but not late-life) had a 26% reduced risk of a dementia diagnosis, while women using hormone therapy only in late-life had a 48% elevated risk compared to women not using hormone therapy at either time point. Women reporting hormone therapy use both in mid and late-life were not statistically different in dementia risk from women not using hormone therapy in mid or late-life. (5). Although promising, more research needs to be done to definitively establish weather estrogen supplementation in the perimenopausal and menopausal period.

No. 142

Aberrant Brain Functional Network Integrity in Adolescents With Insomnia

Poster Presenter: Sanghyun Kim
Co-Authors: Min-Hyeon Park, Subin Park, Bumhee Park, Bung-Nyun Kim

SUMMARY:

INTRODUCTION Adolescence is the a period of rapid brain development, and sleep is very important for the development of adolescent cognitive function, neuroimaging research in adolescents with sleep problems is currently less active than in adults. We investigated the whole-brain functional interactions and network organization of these interactions according to groups classified by insomnia severity. METHODS A total of 802 students between the 7th and 11th grade and their parents were asked to participate to this study. In total, 72 adolescents agreed to participate in this study. The adolescent who scored equal to higher than 8 in ISI total score were classified as insomnia group. The control group was defined as adolescents who scored equal to or lower than 7 in the ISI total score and those who do not have excessive daytime sleepiness symptoms as measured by the ESS scale (?7). We excluded the participants 1) who could not be classified in the insomnia group nor in the control group, 2) who did not complete the survey and 3) whose MRI data quality was too poor to analyze. Finally, data from 47 participants in the insomnia group and 15 participants in the control group were included for analysis. We used 3.0 Tesla MRI scanner. Each

subject was scanned using resting state fMRI protocol for 9.5 minutes. High-resolution T1-weighted images were also obtained from each subject. FMRI data were spatially preprocessed using SPM8, which included realignment of EPI brain volumes for removal of any potential head-motion, co-registration to T1-weighted images, and spatial normalization to a standard common space template using nonlinear transformation procedures. To construct functional network, we extracted fMRI time series from the 116 regions of the automated anatomical labeling map and further processing included regressing out confounding effects, despiking, and band-pass filtering (0.009–0.08 Hz). To improve normality, we converted individual correlation maps into z-scored maps with Fisher's r-to-z transformation. We compared the z-scored maps edge-by-edge between xxx and control subjects using analysis of covariance , with age and gender included as covariates to regress out age and gender-related differences. All resting state-FC analyses were performed using MATLAB-based custom software. RESULTS The resting-state FC differences between adolescents with insomnia and control groups are displayed in Figures 1. Some areas of FC showed negative correlations with the ISI total scores (Figure 2). CONCLUSION We showed several aberrant brain FC characteristics in adolescents with insomnia. These findings suggest that brain dysfunction in adolescents with insomnia extends to spontaneous resting conditions, and cognitive and affective deficits in adolescents with insomnia may stem from the altered FC and brain network organization, which may contribute to other psychiatric consequences and daily functional deficit associated with the condition

No. 143

Demographics, Prescribed Pharmacotherapy and Comorbidities of Disruptive Mood Dysregulation Disorder in Child and Adolescent Psychiatric Outpatients

Poster Presenter: Shayna Bailey, M.D.
Lead Author: Shayna Bailey, M.D.
Co-Authors: Kelly Blankenship, D.O., Russell Fridson, Evonne Edwards, Roseanne Mauch, Irene Warner

SUMMARY:
Objectives: Prior to the addition of Disruptive Mood Dysregulation Disorder (DMDD) to the DSM 5, Bipolar I Disorder (BD) was frequently diagnosed in children and adolescents with chronic non-episodic daily irritability, aggressive temper outbursts and trouble functioning across multiple settings. DMDD was added to the DSM5 in part to reduce misdiagnosis of BD and inappropriate medication management of children and adolescents. As DMDD is a new diagnosis, there are limited protocols guiding medication management of DMDD and a dearth of research discussing demographics, co-morbidities and treatment. This study discusses the demographics, prescribed pharmacotherapy and co-morbidities of children and adolescents diagnosed with DMDD in an outpatient setting. Methods: A retrospective electronic medical record review was completed of patients age 6-18 years who received a diagnosis of DMDD at Pine Rest Christian Mental Health Services outpatient clinics between January 2013 and December 2016 (N = 782). Age, ethnicity, sex, primary and secondary psychiatric diagnoses and prescribed pharmacotherapy were collected and analyzed using descriptive statistics and Chi-square goodness-of-fit tests. Results: Of those diagnosed with DMDD (n = 637), 29.7% were females and 70.3% male. Co-morbid diagnosis included ADHD (71.4%), Anxiety Disorders (30.3%), Autism Spectrum Disorder (ASD)(18.2%), Depressive Disorders (7.4%), PTSD (3.6%), OCD (3.5%), Conduct Disorder (2.5%), Substance Use Disorders (2.0%), Bipolar 2 Disorder (0.8%), Bipolar I disorder (0.2%), and Psychotic Disorders (0.6%). Of patients with a DMDD diagnosis (excluding those with a psychotic disorder, ASD, or bipolar diagnosis), 72.4% (n = 373) were prescribed were prescribed medication typically utilized for mood stabilization, including atypical antipsychotics (64.7%, n = 335), anticonvulsants (21.7%, n = 112) and/or Lithium (2.5%, n = 13). These patients were prescribed SSRIs/SNRIs at a significantly lower rate, ?2(1, N =515) = 153.93, p < .001, with SSRIs/SNRIs prescribed to 48% (n = 247). Twelve percent (n = 61) of patients with a diagnosis of DMDD were prescribed an SSRI/SNRI without a mood stabilizer and 36.3% (n=187) were prescribed a mood stabilizer but not an SSRI/SNRI during that time period. Sixty-three percent were prescribed stimulants (n = 323), 38% (n=194)an alpha- 2 adrenergic receptor agonist, and 9.5% (n=49) atomoxetine. Conclusions: This population of child

and adolescent patients diagnosed with DMDD were approximately two-thirds male. They had high rates of co-morbidity of ADHD, ASD and anxiety disorders. Almost three-fourths of the patients in this sample who were diagnosed with DMDD without co-morbid ASD, psychotic disorders, or bipolar disorders were prescribed a mood stabilizer, including almost two-thirds who were prescribed an atypical antipsychotic. Almost two-thirds of the patients were prescribed were prescribed an SSRI/SNRI.

No. 144

Tranquility of Clonidine

Poster Presenter: Sheldon Brown, M.D.

SUMMARY:

Adults with ADHD have patterns of psychiatric comorbidity and neurocognitive deficits similar to children however due to their responsibilities they suffer a far greater functional impairment. Ideal treatment needs to be effective, as the consequences of adult ADHD pose such a great risk. This is a case of a highly functional patient with ADHD, managed with Adderall 10 mg Qam. The course of treatment was complicated by sleeping difficulties different from insomnia, associated with stimulant usage. The patient admitted to having frequent dialogues with herself, of a non-psychotic nature, about previous-current things, such as conversations and various interactions. The patient also endorsed having her mind occupied with random spelling and other distracting thoughts. A small dose of Clonidine was prescribed which not only helped to induce sleep but it also significantly stopped her internal dialogues and thought distraction. After an online review of ADHD, it's evident that there are similar patients with the exact presentation of a continued internal dialogue, however there is limited use of the medication Clonidine in these cases. This case is meant to inform my fellow colleagues on the potential tranquility benefits of Clonidine within this population of patients.

The Sweetest Decay: A Case Report on an Adolescent Female With Type I Diabetes Mellitus and Suicide Attempts by Insulin Misuse

Poster Presenter: Shynney Marie Munar

SUMMARY:

Given the turbulence of adolescence, adhering to Type I Diabetic management can be precarious, with the demanding, multi-component regimen, comprising of multiple insulin injections, dietary control, and monitoring of blood glucose. Studies showed that 30% of adolescents with Type I Diabetes experienced coping difficulties, feelings of sadness and withdrawal from peers. A tenfold increase in suicide and suicidal ideation was found, with insulin overdose by secret self-administration as the most common method. In the Philippines, there are no published nationwide prevalence or incidence studies on Type 1 diabetes with co-morbid depression in the youth. The case presented multifactorial facets of depression and diabetes leading to noncompliance to both medical and psychiatric treatment leading to suicide. The assessment of Major Depressive Disorder, recurrent was made by thorough review of the psychiatric history and laboratory work up, in accordance with the Diagnostic and Statistical Manual (DSM5). A biopsychosocial approach was done to elucidate the complexity of the case factoring in the adolescent storm, vicious cycle of diabetes and depression and effect of enmeshed attachments. Additional screening tools administered: Diabetes Self Management Questionnaire (DSMQ) and Problem Areas in Diabetes Questionnaire (PAID), showed suboptimal self-care and emotional burn out, respectively. Management involved short-term and long-term goals, focusing on psychoeducation about the nature and course of depression, psychiatric impact of depression leading to noncompliance, suicide precaution and treatment plans through psychopharmacology and psychotherapy (Individual and Cognitive behavioral), family therapy, liaison with the Pediatric Endocrinology and Nutrition service and support group involvement.

A Longitudinal Case Study of ADHD: Identifying Aces and Opportunities for Intervention

Poster Presenter: Vanesa Del Pilar Disla, M.D.
Co-Authors: Matthew W. Grover, M.D., George Alvarado

SUMMARY:

Attention-Deficit/Hyperactivity Disorder (ADHD) is a common psychiatric diagnosis of childhood. The CDC estimates that 11% of all children between the ages of 4-17 have been diagnosed with ADHD as of 2011. Individuals with ADHD experience increased psychiatric morbidity and poor health outcomes as compared to individuals without ADHD. Recent studies have also indicated that children with ADHD have higher exposure to adverse childhood experiences (ACEs), traumatic events before the age of 18 that are experienced as physically or emotionally harmful or threatening, as compared to children without ADHD. A recent study by Brown, et. al. demonstrated an association between the total number of ACEs and moderate to severe ADHD. ACEs can also cofound the patient's diagnosis, as some symptoms common to ADHD may also be indicative of an underlying trauma history. Careful identification of ACEs by pediatricians and psychiatrists can provide an opportunity for further diagnostic clarification and intervention. We present a case of a 15 year-old male with a diagnosis of ADHD and multiple ACEs who was evaluated in the SBH Health System Emergency Department (SBH ED). We will review the association between ACEs and ADHD, possible confounders to the ADHD diagnosis, and point out areas for future intervention.

Off-Label Uses of Clozapine in Children and Adolescents: A Literature Review

Poster Presenter: Vivekananda R. Rachamallu, M.D.
Lead Author: Manish Aligeti, M.D., M.H.A.
Co-Authors: Benjamin W. Elberson, Ph.D., Emily Vutam

SUMMARY:
Clozapine is an atypical antipsychotic approved by the FDA in 2002 for treatment-resistant Schizophrenia and reduction in risk of recurrent suicidal behavior in patients with Schizophrenia or Schizoaffective disorder. Due to the risk of seizures, myocarditis, and the uniquely high risk of agranulocytosis, its prescription is tightly regulated. However, clozapine remains highly effective at treating psychotic symptoms in severely ill patients when multiple antipsychotics have failed. However, there are no FDA indications for the child and adolescent population. The prevalence of early onset Schizophrenia (EOS) is increasing, as is the rate of self-injurious behaviors in children and adolescents. The reason for this increase in EOS is still unclear and likely multi-factorial; it may be due to changing psychosocial factors and rates of substance use. Clozapine has a known role in clinically challenging situations and, as we discuss, can provide significant benefits to treatment-resistant disease. Pediatric patients typically recover with clozapine but do so with an increased risk of chronic and debilitating side effects like metabolic syndrome relative to the adult population. It is therefore helpful to have a summary of clear indications and rationale for when to use clozapine and when it is not indicated and carefully monitor patients for adverse effects. The PubMed database was searched using a date restriction of 1990 to 2017 and including the following keywords: Clozapine, Child, Adolescent, Pediatric, Off-label, and Behavioral. Though it is off-label and relatively few studies exist, we find that there is strong support for the use and relative safety of clozapine in pediatric patients exhibiting behavioral and/or psychotic symptoms. In spite of increased use of antipsychotics in child and adolescent population in clinical practice, there are no recent review articles published focusing on uses of clozapine. Specifically, aggressive, disruptive, or irritable behavior – as well as early-onset Schizophrenia with or without a mood component – is effectively treated with clozapine both in short-term and long-term courses in refractory patients. This population stands to receive significantly greater benefit from clozapine therapy compared to other antipsychotics when criteria are met, thereby limiting long-term morbidity and increasing a patient's functional abilities. While the risk of side-effects is greater in this age group, the benefit outweighs the risk in all found articles.

Parenting Styles and Social Skills of School-Aged Children With Attention-Deficit Hyperactivity Disorder (ADHD)

Poster Presenter: Weeranee Charoenwongsak, M.D.

SUMMARY:
Background Social impairment is not part of diagnostic criteria of attention-deficit hyper activity disorder (ADHD), but is strongly associated with the

condition and still often persists after treatment of primary symptoms through medication and behavioral therapy. Interactions between parents and child, particularly parenting styles, have been found to be associated with wide-range of outcomes in child's life, but very few studies have been conducted in investigating its association with child's social impairment. Objective To examine the association between parenting styles of primary caregivers and social skills of children with ADHD. Methods We investigated the association in a sample of children (6-12 years of age) ,who were diagnosed with ADHD and have received treatment at Southern Institute of Child and Adolescent Mental Health in Surat Thani, Thailand, through questionnaires. Cross-sectional statistical analyses, including Pearson correlation, were used to examine the association between parenting styles and social skills of children with ADHD. Results Total of 221 participants were analyzed; There are a negative correlation between neglectful parenting style and participant's self-control, problem-solving skill, and conflict resolution skill ($p < 0.05$) and a positive correlation between authoritative parenting style and participant's self-confidence ($p < 0.05$) while controlling for primary caregiver sociodemographic factors (marital status, education level, and income), participant's length of received treatment, and medication adherence. Conclusions Neglectful parenting style has been found to be negatively associated with participant's self-control, problem-solving skill, and conflict resolution skill, while authoritative parenting style has been found to be positively associated with participant's self-confidence.

Chart Review of Five Patients With Prolonged Boarding Status in the Emergency Department: A Case Series

Poster Presenter: Yohanis Leonor Anglero Diaz, M.D.
Co-Authors: Michelle P. Durham, M.D., M.P.H., Pamela Hoffman, Kathleen R. Donise, M.D.

SUMMARY:

Emergency departments have experienced an increase in volume of visits, leading to overcrowding and prolonged waiting, increased morbidity and mortality and decreased patient satisfaction .One of the leading causes of emergency department overcrowding is boarding patients in the ED. While not standardized, boarding is waiting 6-24 hours and beyond following a completed evaluation, after the decision to admit or transfer a patient, which cannot be completed due to lack of available beds. Mental health visits constitute about 5% of pediatric ED visits and psychiatric patients are 4.78 times more likely to board in ED than non-psychiatric patients. Although boarding has become common among emergency departments, it seems some patients wait for prolonged periods of time in the emergency department even in comparison to other boarders. There are no formal guidelines on how to identify and address this situation in terms of access to care while patients are waiting for beds. The purpose of our study was to identify the average length of stay for patients during a period of 1 year in an urban academic hospital without a psychiatric unit and to review charts of patients who had the most extended boarding period, seeking to identify factors that could have contributed to extended stay. We obtained retrospective data from charts of all patients who presented to the pediatric ED and required a psychiatric evaluation. IRB approval was obtained and limited data set was provided by institution. Data reviewed included date of presentation, insurance, disposition, psychiatric evaluation and progress notes. We reviewed charts of the 5 patients with the longest length of stay (5 of 461). Results: The average total length of stay in the ED was 1.20 days. The 5 patients who had the longest length of stay ranged from 5.04 to 7.13 days. All presented between January and April and between Thursday and Saturday.3 patients were unable to be transferred due to insurance-related factors. 2 patients were declined due history of aggression. Only 1 patient was transferred to a psychiatric facility while the other 4 were d discharged. In contrast, 58% of patients who boarded between 1.20 days and 5 days were transferred. Conclusions: While the average length of stay in the ED was 1.20 days, some patients waited up to 6 times longer. Factors identified among them include presenting at the end of the week or during January through April and being declined from facilities due to insurance factors or acuity. Most extended boarders were discharged, not transferred to a facility. Identifying factors

associated with extended boarding will lead to advocating for increased resources during times of high utilization and implementing guidelines to improve treatment for patients while boarding in the ED, considering that most do receive treatment in a psychiatric facility but instead their treatment is administered in the ED.

No. 150

Autism Risk Factors: A Study on Autism Spectrum Disorder Population in Las Vegas Metropolitan Area

Poster Presenter: Nina Parikh

SUMMARY:

Autism Spectrum Disorder (ASD) is a chronic condition with varying degrees of impairment and social and behavioral function. Studies show 1 in 68 children have been diagnosed with ASD in this past year. Diagnosis is often made through clinical evaluation paired with a history and observation from the patient's family, all of which are subjective. Despite the growing prevalence of ASD, there is a lack of evidence based data correlating various risk factors with ASD. Our objective is to examine these risk factors associated with ASD population in the greater Las Vegas area. We accessed medical records from the Center of Autism and Developmental Disabilities at Touro University Nevada, that were diagnosed by one neuropsychologist from January 2004 to April 2015 (n=132). We recorded patient's sex, race, family history of; ADHD, ASD, and Learning disability, delivery methods, birth weight, mother's age, mother's income and level of education. We then compared family history of behavioral disorder on the maternal side vs paternal family history and found maternal side risk to have p=.0009. The increasing risk with maternal age over 30, p=.003, specifically between the ages of 31-35 vs. 36-40, p=.001. When comparing risk of Autism and level of maternal education, p= .78. The risk of Autism with family income <$50,000 vs >$50,000, p=.90. The data in comparing between c-section vs vaginal delivery with risk of Autism, p=.32. Retrospective analysis of medical records of 132 patients attending Touro University Nevada Center for Autism and Developmental Disorders (CADD) revealed that, there was a statistically significant correlation of increased risk of ASD in women over the age of 30 specifically from ages 30-34. This finding furthers results conducted from other studies done in Israel, Norway, Australia and Denmark. We also found a significant correlation between maternal family history of ADHD, ASD and learning disabilities more than if the child had family history on the paternal side. This is a novel finding and could have a greater social impact on likelihood of pregnancy in populations with family history. However, we have found no statistical correlation with those that were of lower socioeconomic status, maternal level of education and increased risk of Autism Spectrum in their children. No significant correlation of increased risk of ASD in children that had been delivered by cesarean section versus normal vaginal delivery. Despite other research showing correlation of cesarean sections with ASD, our data found no statistical significance in this aspect. Our primary focus in this study is to narrow the gap between general perception of ASD associated risk factors and that of statistically significant findings, which will help better understand the ASD risk factors and develop novel management strategy.

Reactive Attachment Disorders: A Case Study and Literature Review

Poster Presenter: Stephanie Carbone

SUMMARY:

LB is a 4yo male with a history of severe neglect and attention deficit hyperactivity disorder who presented to the outpatient clinic with his step-mother and newly assigned social worker for complaints of behavioral disturbances. Throughout the interview, LB was noted to get extremely close to the social worker he met only minutes before. This intense attachment, combined with his history of severe neglect provided evidence for a possible attachment disorder. First formally defined in DSM-III, the attachment disorders are comprised of patterns of social behaviors that are markedly disturbed and developmentally inappropriate compared to what is viewed as culturally normal. Until the advent of DSM-5, two types were noted: withdrawn type and disinhibited. Although research has been fairly limited, recent studies have shown

marked differences in the two types, especially in relation to response to intervention. Current diagnostic guidelines now present two distinct disorders: reactive attachment and disinhibited social engagement. This case provides a unique opportunity to look at the impact on patient diagnosis. There are no current case studies on the attachment disorders, let alone making the distinction between the two new diagnoses. Furthermore, research on interventions is at this time extremely limited. The aim of this case is to review what is known about the attachment disorders, provide a framework for diagnosis, and discuss potential interventions particularly as it related to this patient.

No. 153

Case Series: Two Pediatric Patients With Depakote-Induced Blood Dyscrasias

Poster Presenter: Tamara Murphy

SUMMARY:

Depakote (generic: valproic acid or VPA) is a commonly prescribed drug in neurologic and psychiatric medical practices. Its indications include seizure disorders, migraine prophylaxis, and mania. This case series outlines side effects experienced in two pediatric patients prescribed Depakote to treat behavioral symptoms related to Autism Spectrum Disorder (ASD). Depakote acts by increasing the availability of GABA, an inhibitory neurotransmitter, to neurons in the brain (1). Blood dyscrasias are a known potential side effect of Depakote, but researchers are divided on how commonly they occur. Depakote has been known for about 30 years to impair homeostasis, and its effects appear to be dose-dependent. The clinical relevance of this impairment is still controversial. Mild neutropenia and acquired von Willebrand Syndrome (avWS) type I are two of the blood production problems described in the literature (2). Neutropenia usually occurs within the first few weeks of exposure to Depakote and is usually both mild and transient. Reports of neutropenia after Depakote administration are limited in the literature (2). Data on acquired avWS from Depakote are contradictory, and researchers disagree on its exact mechanism and frequency. At least one institute found Depakote-associated coagulopathies to be a frequent finding in its pediatric population (3). Experiments with umbilical cord blood have shown that myeloid progenitor cells are affected by in vitro exposure to Depakote. Terminal differentiation is significantly reduced with continuous drug exposure. Leukocyte subsets are affected differentially, including significantly absolute neutropenia and significantly absolute lymphocytosis. Lymphocyte subsets are also affected, indicating that hematopoietic stem cells or multipotent progenitor cell subsets are impacted by the drug (4). Our case series involves two male pediatric ASD patients who developed hematologic side effects from Depakote. These two cases arose from a practice that serves a pediatric patient population of approximately 500. Patient one developed mild neutropenia and patient two experienced avWS. For the first patient, there was some debate whether the neutropenia could be described by an autoimmune process. We assert, however, that the patient's concomitant mild absolute neutropenia and absolute lymphocytosis are consistent with the effects of Depakote on blood production, as already described within in vitro and in vivo studies. We performed linear regression analysis with SPSS, which showed significant correlation between Depakote dosage and levels of absolute neutrophils and absolute leukocytes in patient 1. For patient 2, vWS testing was consistent with drug-induced avWS, and the patient's symptoms and labs normalized upon discontinuing Depakote. We hope that this case series will add to the discussion of the effects of Depakote on blood production in pediatric patients and their impact on psychiatric and medical decision-making.

No. 154

Case Series: Use of a Combination of Mood Stabilizers in a Pediatric Population With Disruptive, Impulse-Control, and Conduct Disorders

Poster Presenter: Tamara Murphy

SUMMARY:

The DSM 5 describes patients with diagnoses falling under the category Disruptive, Impulse-Control, and Conduct Disorders as having difficulty with self-control of behavior and emotions. Treatment for these conditions is multimodal and includes psychosocial and pharmacological interventions, which are saved for patients for whom symptoms

persist or worsen. To date, few studies have focused on medical treatment of pediatric patients with these disorders. There are no medications licensed specifically for medical treatment of disruptive behavior disorders, but medications have increasingly been used clinically to treat them, largely selected based on comorbidities and side effect profiles (1). Most data so far focuses on treatment with methylphenidate and risperidone. Other antipsychotics have shown efficacy, and there is some evidence that mood stabilizers and other classes may have an effect (2). Mood stabilizers have been investigated in a small number of clinical studies, especially in the treatment of conduct disorder (CD), which showed a moderate reduction of aggressive behaviors. Lithium and depakote are the two most-studied medications to date for CD within this class. There is limited data on typical antipsychotics such as thorazine, but one study described them as having a moderate effect (3). This case series follows the pharmacological treatment of children with Disruptive, Impulse-Control, and Conduct Disorders who were inpatients at a Psychiatric hospital in Huntington, WV under the care of a Child/Adolescent Psychiatrist. Patients within this category of disorders were selected for chart review who had been prescribed one of three medications as first monotherapeutic agent to help stabilize disruptive outbursts: lithium, depakote, or thorazine. After titration of the first medication, patients still experiencing disruptive behavior were given an additional agent and titrated to efficacy. For some patients, a third medication was added. Charts were reviewed for a six-month period for each patient selected for inclusion, and qualitative and quantitative data was gathered and analyzed. Final results are pending, but preliminary results indicate a decrease in outbursts in the selected population with the above-mentioned medications. It is our hope that this case series will add to the data available for the ability of mood stabilizers and typical antipsychotics to reduce disruptive behaviors in children and adolescent patients receiving inpatient treatment for CD.

Diagnostic Dilemma: Just an Obsession or a Debilitating Delusion: A Case Report of Successful Treatment of Schizo-Obsessive Disorder

Poster Presenter: Sagarika Ray, M.D.
Lead Author: Harjasleen Bhullar Yadav, M.B.B.S.
Co-Author: Adam Michael Fogel, D.O.

SUMMARY:
Objective: The term Schizo-obsessive has been known to us since the 19th century, but it has not yet been classified as a diagnostic category in DSM-V. Schizo-obsessive is viewed as the presence of obsessive-compulsive symptoms (OCS) in a patient with either prodromal / active or residual schizophrenia among other criterions suggested by Poyurovsky et al in an article published in 2012. Our case presents a case report of an adolescent patient with likely Schizo-obsessive disorder treated successfully with the combination of a Cognitive Behavioral Therapy (CBT) and Fluoxetine with Aripiprazole at the very outset of the presentation. Our case report focuses on the need for proper diagnosis and establishment of a separate diagnostic category for Schizo-obsessive disorder in DSM-V in order for the timely and accurate pharmacological and social intervention and also focuses on the role of atypical antipsychotics as a treatment modality in such cases. Method: Our patient is a 16 YO Male with a prior history of OCS since the age of 6, and learning disability who presented to us with a swollen left hand, clenched fist, inability to use left hand, deteriorating grades, malodorous, thought disordered, refusing medications with poor insight and negative symptoms which included social withdrawal, diminished speech and avolition. His inability to use the left hand was due to an incident that happened in 2015 when semen from masturbation touched his left hand leading him to be delusional about the hand being contaminated in spite of repeatedly washing the hand. This episode was consistent with schizo-obsessive subtype. Patient scored 24 on Yale Brown Obsessive Compulsive scale, and 33 on Brief Psychiatric Rating Scale. CBT and Fluoxetine were initiated to treat the OCS part and Aripiprazole was added to treat the prodromal phase of Schizophrenia part of the Schizo-obsessive subtype. Results: Patient had failed CBT modality before presenting to us, which was attributed to the existence of untreated prodromal phase of Schizophrenia. Patient showed drastic improvement on the Aripiprazole combined with Fluoxetine provided right at the outset. Conclusions:

We propose that Schizo-obsessive subtype should be added as a separate category in DSM –V in order to enable early identification of psychopathology, and initiate accurate intervention.

No. 156

Understanding Different Treatment Modalities of Trichotillomania and Comorbid ADHD: A Case Report

Poster Presenter: Sagarika Ray, M.D.
Lead Author: Leena Mohan, M.D.

SUMMARY:

Objectives: Trichotillomania (TTM) is a debilitating disorder also known as hair-pulling disorder classified in DSM V as an obsessive-compulsive disorder. It is characterized by repetitive compulsive hair pulling resulting in hair loss which could lead to significant social impairment. Trichotillomania has been viewed as an internalizing disorder or a variant of obsessive-compulsive disorder (OCD). It is known that genetic and environmental risk factors for trichotillomania and OCD are shared within the spectrum of these disorders. Our case describes a 13 year old Caucasian girl who has extensive genetic loading of OCD, ADHD and Depression in her family/ siblings. Our report focuses on not just different treatment modalities of trichotillomania; but also extends to the treatment of co morbid conditions that co exist. Methods: Patient in our specific study failed treatment with an SSRI but responded well to Clomipramine combined with Habit Reversal Therapy. During the course of treatment Clomipramine levels were monitored which were noted to be supra therapeutic. Our case report also reflects on successful treatment of co morbid ADHD without any worsening of trichotillomania symptoms. Results: During the course of treatment it was conclusive that patient did not show any signs of toxicity in spite of having supra therapeutic levels of Clomipramine. Evidence demonstrates that people with varied genetic polymorphisms metabolize Clomipramine in different ways. Our case report also reflects on identification of ADHD symptoms that was unmasked upon treatment of Trichotillomania and subsequent successful treatment of co morbid ADHD without any worsening of trichotillomania symptoms with treatment of stimulant medication. Conclusions: It is interesting to notice that biological underpinnings of OCD and trichotillomania are strongly related and co exist very commonly with other psychiatric disorders like ADHD. Our particular case report reflects on successful treatment of trichotillomania and co morbid ADHD. It also sheds light on the supra therapeutic levels of Clomipramine which may not always result in toxic symptoms in individuals; since varied genetic polymorphisms metabolize Clomipramine differently.

Managing Psychiatric/Behavioral Problems in a Patient With Chromosome 18 Deletion Syndrome

Poster Presenter: Ambika Kattula, M.B.B.S.
Co-Authors: Fei Cao, M.D., Ph.D., Jaskirat Singh Sidhu, M.D.

SUMMARY:

Ms. G is an 18 year-old Caucasian female. She was transferred from a general hospital into our inpatient psychiatric unit due to a suicidal attempt and multiple psychiatric problems. She has a past psychiatric history of bipolar I disorder, schizophrenia, Borderline personality Disorder, Generalized Anxiety Disorder, Autism Spectrum disorder, Intellectual Disability, and a past medical history of gastroesophageal reflux disease (GERD), hypothyroidism and epilepsy. In 2015, she received genetic testing and then was diagnosed with chromosome 18 deletion syndrome. Patient and her two siblings were adopted by her current parents when patient was 3 years old because of child neglect from their biological mother. Apart from her siblings, patient gradually developed multiple psychiatric/behavioral problems as she grew up. As a result, her parents had to send her to a group home 3 year before. Recently her psychiatric/behavioral problems became more severe and she could not get along with her peers and staffs in group home. She also felt that her parents abandoned her, which made her very upset and frustrated. Two weeks before, she made a suicidal attempt by jumping from the 2nd-floor of the group home and broker her spine at the level of T4-5 with minor compression fracture. Patient was sent to a general hospital and received conservative treatments for 2 weeks. After her medical problems were stabilized, she was sent to our inpatient unit for further psychiatric and

behavioral managements. On admission, patient continued to report suicidal and homicidal ideation (patient wanted to take revenge on her family members), auditory hallucination, paranoid delusion, depression, and generalized anxiety. She was then resumed on Depakote (500mg QAM PO and 1000mg QHS PO) for mood, olanzapine (10mg Daily PO) for psychosis, levothyroxine (125 mcg Daily PO) for hypothyroidism, lamotrigine (25mg BID PO) for epilepsy prevention, Pantoprazole (40mg Daily PO) for GERD, Docusate (100mg BID PO) for constipation. Several days later, patient's psychiatric and behavioral problems seemed to be well under control. And her Depakote level was 68. However, one night all of sudden, patient performed very aggressive behaviors, temper tantrum, and tried to bite herself and medical staffs without any cause. This poster will discuss how to manage complex psychiatric and behavioral problems in a patient with chromosome 18 deletion syndrome.

Prevalence, Sociodemographic Factors, and Clinical Correlates of Smoking in the First-Episode and Drug-Naïve Male Schizophrenia Patients

Poster Presenter: Abdullah Bin Mahfodh, M.D.
Co-Author: Fei Cao, M.D., Ph.D.

SUMMARY:

Background: Numerous studies have demonstrated chronic schizophrenia have significantly higher prevalence rates of smoking than either general population or patients with other mental illnesses. However, few systemic studies have investigated tobacco use in the first episode and drug naive (FEDN) schizophrenia patients. This study was to investigate prevalence, and relevant risk factors of smoking and its clinical correlates in the FEDN male schizophrenia patients from a Chinese Han population. Methods: Each participant filled in a detailed questionnaire that recorded general information, sociodemographic characteristics, smoking behaviors, and other medical and psychological conditions. Meanwhile, patients' psychiatric symptoms were assessed using the Positive and Negative Syndrome Scale (PANSS) scores. Smoking data from the 2010 Global Adult Tobacco Survey in China was utilized as the comparison reference. All participants were divided into groups based on their smoking history. Non-smokers were defined as individuals who had smoked less than 100 cigarettes during their whole lifetime. Current smokers were defined as persons who smoked more than one cigarette each day and have smoked for more than 1 year. Results: There were 156 FES male schizophrenia patients participating in this research, among which 50 patients (32.1%) were current smoker, and 106 (67.9 %) as never smoker. Indirectly Standardized Prevalence Ratios of current-smoking patients are significantly lower than ratios from general population (mean ratios=0.60% with 95%CL 0.45%-0.80%). For current FEDN schizophrenia smokers, their age (30.1±9.68 VS 23.09±6.46), education (8.88±4.31 VS 10.29±3.65), age of the first episode onset (28.39±9.65 VS 21.83±6.30), and marriage (x2 = 22. 21, df=2) demonstrated significant difference (all $p < 0.05$) when compared with their non-smoking peers, but no significant difference (all p ? 0.05) in the duration of 1st episode (2.02±1.35 VS 1.84±1.25), BWI (Body Weight index, 21.20±2.73 VS 21.41±3.53), ratios of waist/hip (0.86±0.053 VS 0.84±0.077), PNASS total scores (75.34±18.61 VS 82.72±22.04), PNASS-Positive Scores (19.98±6.97 VS 21.92±8.08), PNASS-Negative Scores (19.80±7.30 VS 21.31±8.78) and PNASS General Psychopathology Scores (35.56±10.71 VS 39.30 ± 11.86). Furthermore, multiple logistic regression showed that only education showed significant difference (OR=0.884, 96%CL=0.789-0.989) between current smokers and non-smoker in our FEDN schizophrenia patients. Conclusion: These results suggest that smoking prevalence in the FEDN male schizophrenia patients was significantly lower than general Chinese population. Only less education could contribute to risks of smoking in the FEDN patients.

No. 159

How Understanding Brain Hypothyroidism Can Improve the Management of Treatment-Resistant Depression

Poster Presenter: Aboelezz Mahmoud Kalboush, M.B.B.S.

SUMMARY:

Over the last 60 years T3 has been used with patients resistant to treatment with different Antidepressants , but the mechanism of action of T3

stayed unknown so far. According to the researches published in some endocrinology journals ; T3 in fact compansates its deficiency in the brain which is a condition called : (brain hypothyroidism) that means deficiency of thyroid hormones in the brain while their levels in the blood are within normal ranges. This medical condition - brain hypothyroidism - happens when different transporters and enzymes involved in the metabolism and utilization of thyroid hormones in the brain are not functioning appropriately. From the clinical point of view , patients with brain hypothyroidism suffer from psychological and mental symptoms which are not easily differentiated from the usual depressive symptoms , but treating those patients with different antidepressants doesn't help and leads to the resistance to the treatment as those patients need T3 , and this may explain why they respond to T3 when added to the antidepressants as augmenting treatment. Understanding the concept of (brain hypothyroidism) can improve the methodology of its detection which can help millions - or even tens of millions - of depressed patients all over the world to be diagnosed - and hence treated - earlier than what happens in clinical practice currently.

No. 160

Clinical Characterization, Mechanisms of Neuropsychiatric Disease in Hyperamonemia and Chronic Urea Cycle Disorder: Longuitidinal Study

Poster Presenter: Ahmed M. Maher, M.D.

SUMMARY:

Urea cycle disorders are metabolic disorder that is characterized with impairment in nitrogen metabolism with resultant accumulation of ammonia in blood and brain. Acute neurologic damage can happen in the acute presentations, with lethargy, vomiting, altered mental status, ataxia, astrexis, brain edema, hypothermia, seizures and coma. Partial enzyme deficiency can result in hyperactive behavior, self-injurious behavior, stroke like episodes and psychiatric symptoms. Glutamatergic models of psychosis propose that dysfunction of N-methyl-D-aspartate (NMDA) receptors, and associated excess of glutamate, may underlie psychotic experiences in people with schizophrenia. However, little is known about the specific relation between glutamate and auditory verbal hallucinations (AVH) in patients with psychosis. In this study, levels of glutamate+glutamine (Glx) in the left lateral prefrontal lobe were determined using proton magnetic resonance spectroscopy (1H MRS) to calculate their association with AVH. The higher Glx levels in patients with lifetime AVH as compared to patients without lifetime AVH suggest a mediating role for Glx in AVH. Our results are consistent with a previous study that found similar decreased levels of Glx in patients with schizophrenia, and increased levels in an AVH group as compared to a NoAVH group. The role of the glutamatergic system deserves further investigation, for example in different brain regions and in relation to clinical variables (Prog Neuropsychopharmacol Biol Psychiatry. 2017 Aug 1;78:132-139) This is a poster reviewing data collected through a longitudinal study from the Urea cycle disorder consortium, about the most common psychiatric presentation for urea cycle disorder patients across multisite data collection.

No. 161

Methionine Synthase Deficiency and Psychosis With Behavioral Outbursts: A Case Study

Poster Presenter: James Preston Ebaugh, M.D.
Co-Authors: Carol Lim, M.D., M.P.H., Samuel Isaac Kohrman, M.D., Barbara Wilson, M.D.

SUMMARY:

Background: Deficiency of methionine synthase results in elevated levels of homocysteine, which could result in mental retardation and psychosis. Homocysteine has been widely researched for its role in neuropsychiatric disorders and mental disorders such as major depression, bipolar disorder, schizophrenia, and schizophrenia-like psychosis. Studies have found elevated levels of homocysteine in young male schizophrenia patients but not in older males or females. Managing psychosis and behavioral problems in a young male patient with methionine synthase deficiency will be explored in this case study. Case History: A 22 year old Caucasian male with Methionine Synthase Deficiency (cobalamine G defect) presented with uncontrolled aggressive behavioral outbursts in the context of noncompliance with medication. His violence is often associated with misunderstanding due to true

delusions and hallucinations. Starting him on risperidone worsened his behavior, which is expected especially when patient do not regularly take their IM methyl cobalamin or hydroxy cobalamin (forms of B12). Patient complained of having “brain issues” and constantly requested a CT scan. He endorsed symptoms of depression with associated psychomotor slowing. He also complained of tingling in hands and feet, which did not respond well to gabapentin, but responded to Pregabalin. Patient also received a monthly injection of Invega Sustenna up to 234mg, which seemed to improve his behavior and psychosis. Plan is to transition to Invega Trinza. Low dose risperidone was given as well as duloxetine, atamoxetine, and propranolol. Conclusion: This case demonstrate how methionine synthase deficiency and high homocysteine plasma level contribute to worsening psychosis especially when the patient is noncompliant with medication. It is crucial to take both medications and antipsychotic to manage the patient. Antipsychotic alone may worsen the behavioral issues. This case provides more insight into the connection between methionine synthase deficiency and psychosis in a young male. It would be interesting to delve into neurobiology of homocysteine causing psychosis and behavioral issues.

No. 162

Immune Signatures and Clinical Course in Schizophrenia

Poster Presenter: Charles Wintour Shaffer, M.D.

SUMMARY:

The pathophysiology of schizophrenia is incompletely understood. A neuro-inflammatory component to the disease has been postulated at various times in the past, and interest in this area has recently increased across multiple domains of inquiry. To address the need for further information on immune mechanisms in schizophrenia as well as the demand for biomarkers in the clinical setting, we used a multiplex assay to characterize a series of 61 plasma cytokines, growth factors, and related molecules in a longitudinal cohort of mostly medicated subjects with chronic schizophrenia (SZ, n=49), bipolar depression (BPD, n=20), mania (BPM, n=20) andhealthy controls (CT, n=101). Biological samples and clinical information were leveraged from an earlier well designed trial, allowing us to control for many important confounders, including sex, age, race and tobacco use. Diagnoses were established using the Structured Clinical Interview for DSM-IV Axis I Disorders (SCID) and SZ symptoms were evaluated with the Positive And Negative Syndrome Scale (PANSS). Samples were collected from patients within 6 weeks of an acute exacerbation of their illness (T1) and then redrawn 6 weeks later (T2). Differences in analyte levels between diagnostic groups were analyzed using factorial ANOVAs to control for confounders. Relationships between marker concentrations and clinical variables in the SZ group were assessed by Spearman’s correlations. In addition, with data reduction methods we developed logistic regression models that used T1 analyte levels to predict SZ diagnosis (SZ v CT) and clinical status of SZ patients at T2 (improved v not improved). Compared to other groups, SZ patients had significantly increased plasma concentrations of 7 analytes at T1 (IL12p40, IL13, CCL4, HGF, Resistin, sICAM1, VCAM1) ($p<.05$). Interestingly, analyses within the SZ group revealed associations between higher concentrations of multiple pro-inflammatory markers at T1 (CXCL9, CSF1, PDGFBB, VEGFA, PlGF1, EGF) and a decrease in PANSS scores over the study period ($p<.05$). Consistent with earlier studies, our findings also showed a positive association between change in IL-10 levels and change in PANSS scores across time points. Results from the logistic regression model predicting clinical improvement were particularly notable for a strong contribution from CSF-1 (OR 8.174; p=0.006), an essential regulator of macrophages including microglia. While preliminary, our results are provocative and suggest a complex disturbance of cytokines and growth factors is present in schizophrenia with implications for future studies on disease mechanism and biomarker

Genetic Testing in Psychiatric Patients Facilitates Long-Term Psychotherapy

Poster Presenter: Gaurav Vishnoi, M.D.

SUMMARY:

Title: Genetic testing in psychiatric patients facilitates long-term psychotherapy Background:

People often equate high doses of antidepressants with severity of depression but it is more closely correlated with refractoriness to drug treatment. This case report highlights the importance of genetic testing in these patients. The patient is a 60-year-old Irish-American woman who has been undergoing treatment with high doses of multiple medications for her depression with little response, if any. On further evaluation, it is found that she has lifelong history of unrecognized Adult ADHD(she lost several jobs because of inattention to details, poor time management) and is found to be positive for Val/Val COMT gene which is a marker for ADHD and has been proposed to be the cause of impairment of short-term memory in these patients. ADHD symptoms are further impaired by smoking marijuana as in this patient. Psychosocial background includes that patient is Irish-catholic. Being blamed (for example blaming the victim for failure at school) and guilt is a big part of her culture that she has internalized over years. Also, there is a high incidence of alcoholism and depression in Irish population; hence genetic loading was in favor of depression in the current patient. She sought help for her depression over years but did not respond. Unfortunately, her treatment providers blamed her for not taking medications. Augmentation with atypical antipsychotic medications like Olanzapine and Abilify did not work for this patient. Results of her genetic testing: As per her genetic testing report medications which she can take included- MAOIs- She did not want to take MAOIs because of dietary restrictions. Good CBT with a partial response from Meds. She needs and would benefit from good support from psychotherapy. Also, she could be persuaded to try MAOIs later during her CBT sessions. Bupropion- has a ceiling of 450 mg as the patient is a rapid metabolizer., so she achieves sub therapeutic blood levels.

Cardio-Metabolic Risk Factors With Different Antipsychotics in Early Psychosis Patients

Poster Presenter: Gaurav Vishnoi, M.D.

SUMMARY:

BACKGROUND: Schizophrenic patients have high cardiovascular mortality. Characterization of risk factors during their first inpatient hospitalization is less clear and may be helpful for early preventive interventions. Objectives of the study were to: 1) Determine the prevalence of cardio-metabolic risk factors and duration of untreated psychosis in First Episode Psychosis (FEP) patients treated in a specialized FEP inpatient unit and 2) Study the relationship of these risk factors with the type of antipsychotic treatment. PRACTICE GAP: Approximately 100,000 adolescents and young adults in the United States experience First Episode Psychosis(FEP) each year. The data related to baseline cardio-metabolic risk factors in early psychosis patients are relatively scarce. The aim of this study is to better characterize the cardio-metabolic health of FEP patients treated in a specialized FEP unit, and their relationship to type of antipsychotic treatment. METHOD: Data for early psychosis patients (with a DSM-5 diagnosis) admitted to a specialized first episode psychosis inpatient unit was collected and analyzed for baseline cardio-metabolic risk factors. All participants had experienced only one episode of psychosis (individuals with a psychotic episode followed by full symptom remission and relapse to another psychotic episode and those with >6 months of lifetime antipsychotic medications were excluded). Mean +/- standard deviation was calculated and data were compared using student's t-test. RESULTS: 80 patients (73 males; 7 females with age 16 to 23 years) were included in the study. Only 4 out of 80 patients had elevated blood pressure at baseline. Mean HBA1C was 5.2±0.47; total cholesterol was 157± 33.6, triglycerides were 79.3±36.9, LDL was 89.4±23.8 and HDL was 40.96± 9.2. The median duration of untreated psychosis was 165 days (range of 1 day to 12 years on first admission). On admission, 15 percent (12/80) were either overweight or obese. Antipsychotics included Haldol, Risperidone, Olanzapine, Ziprasidone, and Aripriprazole. Average weight gain (in kgs) on discharge was 2.6 (65.8±10.1 to 68.4±9.8 ; $p<0.001$) while an increase in BMI was 0.7(22.8±4.7 to 23.5±4.9 ; $p< 0.001$). On Risperdal, patients gained 6.03±4.7,; on Olanzapine average weight gain was 7.15±3.4; on Haldol average weight gain was 4.5±4.2 while on others(Aripiprazole and Ziprasidone), it was 0.37±0.24) kgs CONCLUSIONS: In FEP patients, cardio-metabolic risk factors are present early in the illness and likely related to unhealthy lifestyle and

antipsychotic medications. Early interventions including exercise, dietary restrictions, close medical monitoring and appropriate choice of antipsychotics starting during first hospitalization itself, may be helpful as prevention strategies.

No. 165

Hospitalized Indian-American Inpatients and Their Unique Stressors: A Case Series

Poster Presenter: Jasmine Malika Singh, D.O.

SUMMARY:

Background: Recent immigrants are a psychiatrically underserved population. Various interventions to promote assimilation and mental wellbeing have been identified, including assistance with English, access to mental health services, attaining employment, and promotion of family connections. There are over 2.8 million Indian-born immigrants in the United States (2010 Census), and this population may have specific and unique psychological stressors that have not been addressed in the current literature. In general, Indian-Americans speak English and are mostly employed, factors that promote assimilation that can be absent in other immigrant populations. To explore the psychosocial stressors that Indian-Americans do experience, we performed a small case series review of clinical experiences of adult Indian-American psychiatric inpatients. Methods: A case review was performed on six adult first generation Indian-American patients who were hospitalized on an inpatient psychiatric unit within a 3-month period. These patients had a mean age of 48 with a standard deviation of 14, and their length of stay ranged from 3-18 days. The sample consisted of 3 male and 3 female patients. Their admission diagnoses included severe MDD, without psychotic features, bipolar I disorder in a manic state, various substance use disorders, and schizophrenia. The patients were stabilized on psychotropic medications, including antipsychotic medications. Results: During the hospitalization, insight and function improved in all patients. Patients expressed satisfaction with treatment. Four patients reported family as a negative, chronic stressor. Three patients cited cultural differences between child and parent as a chronic stressor in their lives. These patients' chronic issues with immigration, assimilation, cultural, and family issues appear to have contributed to their major episodes of psychiatric illness. Conclusions/Future Directions: After a preliminary case review, unique psychosocial stressors are emerging for the Indian-American population. Indian-Americans cite family as a negative stressor, as opposed to other immigrant populations who see family as an aid and coping mechanism in immigration and assimilation. Cultural differences between immigrant parent and first-generation American born child were also expressed as a stressor. Also, a lack of awareness of mental health is another issue these patients exhibited. These cases illustrate potentially unique mental health issues faced by this population. Specific interventions may benefit this population to promote wellbeing, such as the innovation of an assimilation tool to promote biculturalism and assimilation into both native and host cultures, mental health awareness by way of education and community outreach programs, as well as cohesion in the family unit especially in the child-parent relationship. Cases will be continued to be collected with a goal to generate an overall sample of 10 cases.

No. 166

Mental Health and Psychosocial Problems Among Victims of Earthquake in Nepal

Poster Presenter: Shree Ram Ghimire, M.D.

SUMMARY:

Background: Despite earthquakes being the most common and devastating natural disasters, relatively little attention has been paid to their mental health consequences. The risk for mental health and psychosocial problems has substantially increased among the earthquake affected population in Nepal. The aim of the study was to reveal psychological distress and to explore the mental health and psychosocial problems in the earthquake affected population of four districts in Nepal immediately after the disaster. Methods: The study population was a total of 518 patients attending an emergency mental health camp conducted during the two weeks after the mega earthquake in 4 different affected districts of Nepal. The patients were first screened by the general medical health camp using exclusion and inclusion criteria. Each patient was

then asked to list the symptoms that they developed as a consequence of earthquake in local language after taking the socio demographic details. The data was then analyzed. No syndromal diagnosis was made for the study. Results: Out of 412 respondents, the majority was females (58.65%) and the most patients were in the age groups of between 25 to 35 years. Among the symptoms, fearfulness, shaking, sleep disturbances, avoidance, and worries were consistently reported in majority of the patients. The other rare symptoms reported were mutism, suicidal ideation, bed wetting, and isolation. Women, children, and elderly were the most severely affected age groups. Conclusion: Mental health and psychosocial problems immediately after humanitarian crises are common but transient. Different positive coping mechanisms, access to social support networks, family and community support, talking with friends, and engaging in work or religious activities help minimize the psychological problems. Lack of such support might result in long term consequences. The Psychological First Aid provided by Disaster Psychiatry Outreach was also able to reduce the initial distress and foster short and long-term adaptive functioning. A need exists for strengthening the psychological first aid system in disaster prone regions, especially in the developing countries like Nepal.

No. 167

Assessment of Community Needs and Association Between Mental Health Problems and Risk Behaviors

Poster Presenter: Leslie Bardessono, D.O.
Co-Authors: Suporn Sukpraprut-Braaten, Andrew J. Powell, M.D., Conrad Braaten

SUMMARY:

Background: The Disease Control and Prevention (CDC) focused on decreasing the following six priority health-risk behaviors including alcohol and other drug use, unemotional injuries and violence, tobacco use, unhealthy dietary behavior, physical inactivity, and sexual behaviors that contribute to unintended teen pregnancy and sexual transmitted infections.1-3 This study focus on assess community needs among underserved population in Arkansas and determining associations between physical and mental health problems on health risk behaviors. Methods: A cross-sectional study was conducted via a community-wide survey among uninsured and underinsured residents of White County and nearby counties in Arkansas. The survey collected demographic information, general health, sleep and exercise, tobacco use, and mental health related questions. Statistical Package R version 3.4.0 was used to compute descriptive statistics, Pearson's correlation, and odds ratio. Results: Total of 96 adults completed the survey (mean age=38±12 year old, 21% are males). 65% of the responders stated that they had no visit to a doctor in the past 3 years or longer. Only 4% of the responders had a routine health checkup. On average, number of days that pain made it hard for them to conduct usual activities, such as self-care, work, or recreation was 10 days; number of days they felt sad, blue, or depressed was 8 days; number of hours of sleep they get within a 24-hour period was 7 hours. 68% of the responders stated that they were dissatisfied with their lives. There was a significant association between the responders who has social and emotional they need and number of cigarettes smoking each day (Pearson's correlation=0.239, p-value=0.0192) and between number of days they feel sad, blue, and depressed and number of cigarettes smoking each day (Pearson's correlation=0.220, p-value=0.0156). Responders who do not participate in any physical actives or exercises such as walking or gardening were 5.4 times more likely to report to have serious difficulty in concentrating, remembering, or making decisions (odds ratio=5.4, 95% CI=2.11 and 13.6, p-value=0.000265). Conclusion: These results revealed the needs of psychiatrists, psychologist or other health care providers for the people with mental health problems in the severely underserved population would benefit on reducing their health risk behaviors such as smoking and lack of physical activity and improving their concentrating, remembering, or making decisions. The results from this study could help to reduce several of the six CDC health risk behaviors focus areas especially in underserved areas.

No. 168

Diagnostic Challenges of a Hearing-Impaired Male Reporting Auditory Hallucinations

Poster Presenter: Uruj Kamal, M.D.

Co-Authors: Steven V. Fischel, M.D., Ph.D., Sara A. Brewer, M.D.

SUMMARY:
Auditory hallucinations are a hallmark of Schizophrenia, paranoid type but understanding the etiology of auditory hallucinations in a patient who is deaf raises more complicated diagnostic considerations. In this case report we discuss a hearing impaired patient who presented to clinic carrying a prior diagnosis of Schizophrenia and who reported auditory hallucinations. Mr. P, a 52 year old Caucasian hearing impaired male in DMH care carrying a longstanding diagnosis of Schizophrenia secondary to auditory hallucinations and alcohol use disorder in full remission, presents to the outpatient clinic for follow up of his Invega Sustenna injection and long term management. The patient had recently been admitted to an inpatient psychiatric unit for physical aggression and sexually inappropriate comments that were made to staff in his outpatient clinic that were interpreted as an immediate threat to himself and others and associated with a psychotic decompensation. During the outpatient clinic intake, Mr. P explained that he was inappropriately sent to the inpatient psychiatric ward because his aggressive signing was interpreted as 'psychotic gesticulations.' He said that instead, he was trying to ask facility staff members why there was a delay in his disability check and was asking how to address issues with his DMH subsidized apartment. Previously, the inpatient psychiatric team had considered the differential diagnosis of Schizophrenia with decompensation, adjustment disorder with severe anxiety or PTSD. Of note, the patient adamantly expressed his dislike for the Schizophrenia diagnosis and found it traumatizing. Interestingly, staff members on the unit felt that when the patient aggressively signed to providers when trying to communicate something about his unwarranted Schizophrenia diagnosis, he instead appeared to be responding to internal stimuli. Additionally, Mr. P himself did note that Risperdal helped him with moments of 'emotional rage.' It was suspected by this clinician that the patient's affective and emotional dysregulation was secondary to an underlying character pathology as well as resentment towards the medical world for not understanding his communication barriers. The patient explained to the outpatient team that his auditory hallucinations are his own way of processing insults from the outside world. In this poster, we will (1) explore the diagnostic challenges involved in working with a deaf patient who reported auditory hallucinations (2) discuss the importance of an emotional vs. psychotic etiology of symptoms in this patient (3) address treatment options for auditory hallucinations in the deaf population.

No. 169

A Critical Review of the Affects of Maternal SSRI Use During Pregnancy on Attention-Deficit/Hyperactivity Disorder and Non-Autistic Learning Disorders

Poster Presenter: Uruj Kamal, M.D.
Co-Authors: Nancy Byatt, D.O., M.B.A., M.S., Valerie C. Sharpe, M.D.

SUMMARY:
Objective: Perinatal depression is common and associated with poor maternal, birth, and child outcomes. It is often treated with selective serotonin reuptake inhibitors (SSRIs), which have been associated with the Neurodevelopmental Disorders including intellectual disabilities, communication disorder, motor disorders, specific learning disorders and attention-deficit/hyperactivity disorder (ADHD). There is a dearth of critical reviews examining the relationship between SSRI use in pregnancy and ADHD and non-autism spectrum illnesses. Our aim is to examine the extent to which SSRI use in pregnancy is associated with non-autistic learning disorders in offspring including ADHD, intellectual disability, motor disorders, communication disorders and learning disorders. Method: We searched PubMed/MEDLINE from Jan 2009 to July 2017 for human studies using the terms SSRI, pregnancy, ADHD, neurodevelopment, intellectual development, motor, communication and learning disorders and reviewed 12 articles (9 studies): 5 cohort studies, 1 prospective population based study, 2 prospective longitudinal studies, and 1 retrospective case control study. Results: The six cohort studies did not demonstrate a statistically significant association between prenatal SSRI exposure and ADHD, or cognitive, motor, language or behavioral outcomes with low hazard ratios while

adjusting for confounders. One study using claims based data found that second trimester exposure to Bupropion during was associated with offspring ADHD (OR= 3.63) although exposure to SSRIs was not associated with offspring ADHD (OR= 0.91). A population based study did not show a change in executive function at 5 years, non-verbal intelligence at age 5, or neuropsychological function at 7 years in 71 offspring prenatally exposed to SSRIs. A retrospective case control study showed comparable mean standard deviations on the mental developmental index score (94 +/- 15 vs. 91 +/- 10) and psychomotor developmental index scores (79 +/- 21 vs. 75 +/- 20) for in utero SSRI exposure infants vs. placebo, respectively. Conclusion: There were no statistically significant associations between maternal SSRI use and ADHD or other neurodevelopmental disorders. Untreated maternal depression can have negative impacts on impulse control in children. It is important to educate parents and providers about potential risks and benefits of taking psychotropic medications in pregnancy with an understanding that risks associated with untreated maternal depression and anxiety could be greater than risks associated with SSRI use during pregnancy.

No. 170

Is Ambivalence in Pregnancy Pathological? The Role of Psychodynamic Interventions in Treating Depression in a Desired Yet Conflicted Pregnancy

Poster Presenter: Anne Clark-Raymond, M.D.
Co-Author: Alison Draut Hermann, M.D.

SUMMARY:

Depression in the perinatal period is a major public health concern, affecting 14-23% of women antepartum, and up to 25% of women postpartum. The 2015 ACOG committee opinion recommends that pregnant women be screened at least once for mood disturbance. However, less than 20% of women eventually diagnosed with postpartum depression had revealed their symptoms to a healthcare provider. Significant shame and guilt may be barriers to women seeking psychiatric attention, and may relate to an ambivalence towards pregnancy. Ambivalence towards becoming a mother has in the past been presumed to be pathological, and is associated with antenatal depression. This ambivalence has often been thought to result from challenges facing women with lower socioeconomic status, poor social support, a history of sexual or physical trauma, unplanned pregnancies, and obstetrical complications and miscarriages – all known risk factors of perinatal depression. However, the literature also suggests that a woman's conflicts regarding motherhood may be uniquely individual, and relate to her own internal expectations of what motherhood will be, regardless of her number of classical risk factors. We present the case of a 34 year-old married woman, gainfully employed with a graduate degree level education, planning a pregnancy with her spouse, yet facing significant ambivalence upon discovering that she was pregnant. Her resulting severe major depressive episode was treated with an SSRI and CBT, and she initially achieved partial remission. Psychodynamic psychotherapy was then begun to target residual depressive symptoms prior to giving birth. We propose that ambivalence toward motherhood is actually normal, but that a precipitous depressive episode triggered by pregnancy such as this one may reveal underlying psychodynamic conflicts related to themes of dependency, autonomy, and control. An inability of the mother to reconcile her conflicts regarding pregnancy can result in pathology including depression and anxiety disorders, as well as obsessional and psychotic pathology, which can have devastating effects on the mother's and baby's health and on attachment and bonding. Shame and guilt over ambivalence may prohibit patients from disclosing it to providers, thus preventing earlier psychotherapeutic intervention. Likewise, mental health professionals may also be hesitant to engage in uncovering work exploring pregnancy ambivalence for fear of destabilizing fragile patients in the peripartum period, therefore missing an opportunity to effectively treat an important cause of depression. Perinatal ambivalence should be sensitively attuned to by clinicians, and patients should be promptly referred for psychotherapy to explore emotional conflicts. Furthermore, it may be imperative to address these conflicts using psychodynamic psychotherapy in order to fully remit the patient's depression and facilitate her transition to motherhood.

No. 171

A Case of Peripartum Depression in the CPEP

Poster Presenter: Bronwyn Huggins, M.D.

SUMMARY:

Ms. B is a 42 year old unmarried female who presented to the psychiatric emergency room at a university hospital who self presented accompanied by a friend, with symptoms of anhedonia, inability to care for self or 9-year old daughter, diffuse numbness, increasingly distracted, guilt and difficulty maintaining sleep, poor appetite for the last five months. Patient was five months pregnant and expressed desire to abort her baby because she believed the unborn child was the cause of her depressive symptoms. Ms. B reported a history of similar depressive episodes during her three other pregnancies, with resolution of symptoms following delivery. During her second pregnancy, sixteen years ago, patient reports that she was admitted for 3 months for her depressive symptoms and underwent 2 ECT, although did not continue due to concerns regarding the use of anesthetics. She says that with her last pregnancy, she developed symptoms during the first trimester, but was unable to 'cope' and refused SSRIs for concerns of the fetus. She recently began a trial of Citalopram 20 mg po daily, 3 weeks ago for her mood disturbance. On assessment, it was learned that patient's psychiatric history is significant for major depressive episodes, all of which occurred exclusively during the peripartum periods of her four pregnancies, with the exception of her first depressive episode in her mid-twenties. She also revealed history of one suicide attempt a few years ago, by pill ingestion, weekly cannabis use, and has a long history of panic attacks, which have increased in frequency during the last five months (1-2x per week). Ms. B reported that her father suffered from depression and denied any past medical history. Ob/GYN was consulted and medically cleared both mother and fetus. She was admitted to the inpatient psychiatric unit for continued observation with concerns for her safety and potential harm to her unborn child. In this poster, I advocate for further investigation into a demographic of women who experience primarily, peripartum depression, with resolution of symptoms following delivery. I would like to raise awareness to this type of mood dysregulation during this period of time, which is in contrast to the majority of investigations that focus on the postpartum period. This may lead to better understanding of the distinctions between the two, and perhaps generate further inquiry in treatment discrepancies as well. It also highlights a need for conducting studies to explore the prevalence, and psychosocial impact of exclusively peripartum depressive disorder.

No. 172

Perinatal Anxiety Disorders in Singapore

Poster Presenter: Cornelia Chee

SUMMARY:

Introduction: Perinatal anxiety disorders are much less well characterized and described in the literature compared to perinatal mood disorders. We studied women whom we screened for perinatal psychological distress at a tertiary hospital in Singapore Method: Women attending obstetric clinics at the National University Hospital of Singapore between 2008 and 2016 were screened for psychological distress using the Edinburgh Postnatal Depression Scale (EPDS) during their pregnancies or at their six week postnatal visit. Women who scored 13 or more on the EPDS were contacted by case managers and assessed using clinical interview. We also used the Global Assessment of Functioning (GAF) to estimate the functioning of these women. Results: Out of 901 women who were interviewed, 107 women had some form of anxiety disorder, 315 women had major depressive disorder, and 479 women were deemed to have no mental illness. Of the women with an anxiety disorder, 19% were diagnosed with Obsessive Compulsive Disorder, 20% were diagnosed as having Panic disorder, 57% were diagnosed as having Anxiety Disorder NOS (as few women could meet the time criteria for GAD), 4% were diagnosed as having Post-traumatic Stress Disorder (PTSD), and 1% with Social Anxiety Disorder. Women diagnosed with Anxiety disorders were significantly older (M= 31.3 , s.d.=4.1) than women diagnosed with MDD (M= 29.9 , s.d.=5.7) or those who had no mental illness (M= 29.3 , SD=5.6); ($F_{2,890} = 5.88$, $p = .003$). Women diagnosed with MDD scored significantly higher on the EPDS (M= 17.5, s.d.=4.2), than women diagnosed with Anxiety related disorders (M= 15.5 ,

s.d.=5.54) and those who had no mental illness (M= 13.2 , s.d.=3.36) ; (F2,825 = 108.98, p < .001). Women diagnosed with Anxiety related disorders had significantly lower Global Assessment of Functioning (GAF) scores (M= 50.1 , s.d.=26.6) than those who had no mental illness (M= 60.9, SD= 31.2) and women diagnosed with MDD (M= 54.4 , SD=21); (F2,898 = 9.72, p < .001). Conclusion: Women with perinatal anxiety disorders constitute a small but significant proportion of women who report perinatal psychological distress on a self-rated instrument such as the EPDS. They also have characteristics which are different from women with MDD, and may possibly have poorer overall level of functioning.

No. 173

Clinical and Ethical Challenges in the Care of the Parturient Patient With Florid Psychosis

Poster Presenter: Danielle Epstein, D.O.
Co-Authors: Jacqueline A. Hobbs, M.D., Kay Roussos-Ross

SUMMARY:

Managing care of patients with major mental disorders requires a careful balance between patient autonomy and the need to protect health-related interests in these vulnerable individuals whose cognition and judgment are often compromised. Nowhere is this more pertinent than in the intrapartum patient, where the well-being of both mother and fetus can be affected. A 36-year-old G10P2435 female at 37w6d presented to the Emergency Department via law enforcement involuntarily with symptoms consistent with acute psychosis and substance intoxication. The patient had a past medical history notable for unspecified bipolar disorder coupled with ongoing substance use disorder. Previous pregnancies had been complicated by substance use and major depressive disorder, without psychotic features, with peripartum onset. She was felt to be in the early stages of labor and was therefore admitted to the High-Risk Obstetrics Team. The patient's behavior was agitated, erratic, and frequently violent with staff secondary to ongoing paranoid ideations. She consistently refused psychiatric and medical interventions, including fetal monitoring. Although active labor was ruled out, several severe-range blood pressures were measured, concerning for the development of preeclampsia. Standard obstetric practice dictated induction of labor, which the patient refused. On interviews, the patient clearly lacked medical decision-making capacity, as she still endorsed prominent delusions, with the belief that providers were plotting with the FBI to control her. To ensure ethical and legal standards were followed in the fast-paced treatment of this urgent case, psychiatric and obstetric teams sought guidance from the hospital legal counsel. Using surrogate decision making, the patient's mother was identified as a suitable proxy to obtain formal consent. Ongoing efforts to form a therapeutic alliance between healthcare staff and the patient slowly succeeded and allowed for increased monitoring of mother and baby. Providers worked with the patient to further gain trust, utilizing assisted decision making and respectful persuasion to restore capacity and were successful in obtaining verbal consent for induction of labor with possible operative delivery. Labor resulted in an unremarkable vaginal delivery. In non-emergent cases such as these where court injunctions are unobtainable, establishing a working relationship with impaired patients is crucial for the health of mother and baby. By identifying gaps in knowledge and deriving shared goals, the treatment team can optimize cooperativity and reverse diminishments in capacity while respecting patient autonomy.

No. 174

Access to Abortion Services: Mental Health Impacts and Outcomes

Poster Presenter: Mandar Jadhav, M.D.

SUMMARY:

Authors: Mandar Jadhav, MD, Andrew Matrick, Salman Majeed, MD Background: Suicidality during pregnancy could reasonably be attributed in part to the limited options women, especially teenage mothers, may have when faced with an unplanned pregnancy. However, research in this area to ascertain some semblance of causality is quite limited. This may be in part due to suicide being excluded traditionally as a cause of 'maternal death' in widely collected mortality statistics, among other ethical, political, social restrictions in collecting reliable data on the subject. Hence why, when

providing care to one such teenage mother on our inpatient unit, we had limited professional guidance available to us. Hypothesis: Limited access to abortion services can lead to increased risk of suicidality & self-harm behavior in teenage mothers. Methods: Brief review of extant literature relevant to the subject at hand. Case report on one patient seen in the inpatient psychiatric care setting in particular. Discussion of widely applicable tenets derived from the literature as illustrated by the case. New or previously under-emphasized elements pertaining to impact of limited access to abortion on women's mental health are also highlighted. Results: Clear and present danger to the mental health & wellbeing of young women is posed by wantonly limiting access to abortion services. However, there is also a known association between increased prevalence of mental illness after obtaining an abortion, which must be considered on a case by case basis. Conclusion: Awareness of mental health impact of this issue must be raised more broadly so clinicians and other supportive services personnel coming in contact with this vulnerable population can act to intervene early and prevent both undue morbidity and mortality.

No. 175

Meta-Analysis of Prenatal Antidepressant Exposure as Risk Factor for Autism: Impact of Comparison Group Definition

Poster Presenter: Monica Lynn Vega, M.D.
Co-Authors: Graham Newport, Durim Bozhdaraj, M.D., Samantha B. Saltz, M.D., Charles Barnet Nemeroff, M.D., Ph.D., D. Jeffrey Newport, M.D.

SUMMARY:
Background: A 2014 position statement by the US Dept. of HHS Agency for Healthcare Research and Quality (AHRQ) posited that studies of prenatal antidepressant (AD) safety are "inadequate to allow well-informed decisions . . . because comparison groups were not exclusively depressed women". Illustrating this concern, existing meta-analyses, concluding prenatal AD exposure is associated with autism, have failed to evaluate the impact of comparison group designation. The current meta-analysis addresses this gap in the literature. Methods: A search of 7 databases was performed with keywords including antidepressant or selective serotonin reuptake inhibitor (SSRI), pregnancy, and autism. Observational studies reporting odds (OR) or hazard (HR) ratios for autism following AD exposure qualified. Analyses of prenatal SSRI or AD exposure were performed. Subgroup analyses stratified by population, psychiatric, and sibling comparison groups, and a final composite analysis were conducted. Statistical analyses were performed using Comprehensive Meta Analysis software. Results: Fourteen studies (8 cohort, 6 case-control) were included. Thirteen studies reported results using a population-based comparison group. Psychiatric and discordant sibling comparison groups were reported by 5 and 4 studies respectively. Population-based analyses uniformly produced significant estimates of autism for exposure to any AD (HR= 1.42 [95% CI: 1.22-1.65]; OR=1.43 [95%CI: 1.21-1.68]) or SSRI (HR= 1.53 [95% CI: 1.37-1.72]; OR=1.55 [95%CI: 1.36-1.75]). Conversely, psychiatric comparison groups demonstrated no significant associations for AD (HR= 1.16 [95% CI: 0.79-1.72]; OR=1.12 [95%CI: 0.84-1.48]) or SSRI (HR= 1.25 [95% CI: 0.79-1.79] OR=0.99 [95%CI: 0.65-1.52]) exposure. Analyses of siblings discordant for autism, arguably enhancing control for both heritability and psychiatric illness risk, suggested SSRI exposure may even afford protective effects (OR=0.79 [95%CI: 0.65-0.97). Other estimates using the sibling comparison group for ADs (HR= 0.95 [95% CI: 0.69-1.31]; OR=0.87 [95%CI: 0.58-1.30]) or SSRIs (HR= 0.82 [95% CI: 0.60-1.12]) were insignificant. A final composite analysis demonstrated no significant effect of exposure to ADs (HR= 0.97 [95% CI: 0.83-1.14]; OR=1.16 [95%CI: 0.88-1.51]) or SSRIs (HR= 0.99 [95% CI: 0.82-1.21]]; OR=1.18 [95%CI: 0.93-1.51]). Results limited to first trimester exposure were similar. Conclusion: Underscoring concerns raised by the AHRQ, study design, particularly alternative means of defining and selecting comparison groups, leads to discordant conclusions regarding the risk for autism conveyed by prenatal AD exposure. Although population-based comparisons suggest that AD exposure increases autism risk, psychiatric and family-based comparisons do not support this conclusion. Future studies evaluating risks of fetal AD exposure should attend to this important research design concern.

Management of PTSD and Anxiety in a Pregnant Patient With Substance Use Disorders

Poster Presenter: Yon Park

SUMMARY:

Ms. A is a 29-year-old African American female with a history of postpartum depression and tobacco use disorder, who presented to the community outpatient clinic with complaints of difficulty sleeping, depressed mood, and poor appetite in context of recent murder of 15-year-old son. The patient is a single mother with two small children, attends online college, and has a poor familial support system. She smokes 1-2 cigarettes daily but is trying to cut down. She also has a history of sexual molestation by a stepfather when she was a pre-adolescent, and a history of domestic violence by previous partners. Her family history included substance use in both parents, Her episode of postpartum depression was after the birth of her nine-year-old daughter. She experienced tearfulness and sadness and was prescribed Lexapro and attended therapy at another clinic. She was undergoing pre-trial proceedings of her son's murderer and complained of worsening symptoms recently. She discovered she was 12 weeks pregnant and was unsure if she would like to keep the baby. She was educated on the risks and benefits of medication management during pregnancy and started on Prozac for depression and anxiety symptoms, and Benadryl at bedtime as needed for sleep. She was also recommended to come in weekly for supportive therapy through this difficult time. In the next few months, she presented sporadically at the outpatient clinic. She continued to struggle with grief and decided to keep her baby. She was still smoking cigarettes and also revealed that she was diverting a family member's Xanax prescription to self medicate her anxiety. She was also using Prozac on an as needed basis to cope with moments of increased anxiety and panic. Several sessions were spent on psychoeducation of antidepressants, management of anxiety, and the harmful effects of benzodiazapines to the fetus. She was strongly encouraged to come to therapy more regularly. This poster aims to examine the literature on current treatment of anxiety and PTSD symptoms in pregnant women, current recommendations of treatment for pregnant patients with comorbid anxiety and depression, and the challenges of treatment in this specific patient with active tobacco use and a tendency to self medicate.

No. 178

The Correlation Between Symptoms Orthorexia Nervosa and Health Anxiety: Findings From a Survey of Health Professionals

Poster Presenter: Yon Park

Co-Author: Rebecca Sokal

SUMMARY:

Background: In the last decade, the term orthorexia nervosa (ON) has been used to characterize a set of specific disordered eating symptoms, including preoccupation with health and healthy foods and obsession with the quality or purity of food . ON was first introduced in 1996 in an article by Dr. Bratman and since then, several case reports and small population screening studies have been conducted in Europe and the U.S. Prevalence rates vary from 1% in a small US student sample to 70% in a nutrition student sample; however, additional research needs to be conducted to have a more reliable understanding of prevalence. ON is not recognized in the DSM-5. In fact, there is wide debate regarding whether it should be identified as its own eating disorder (ED) entity or whether it should fall under pre-existing diagnoses like anorexia nervosa (AN) or ARFID, or a category outside EDs, such as obsessive compulsive disorder or somatoform disorder. While there have been studies assessing the prevalence of ON, there have been few studies attempting to distinguish characteristics of ON from those of other EDs. Current literature, as well as clinical experience, suggests that health anxiety may play a significant role in the development of ON symptoms. This is in contrast to AN in which behaviors are driven by a desire to be thin or an obsession with body image. With this study, we aim to determine whether or not ON symptoms are positively correlated with health anxiety and whether this establishes a key point of divergence between ON and AN. Methods: We formulated a 15 item survey with questions adapted from the ORTO-15 questionnaire to screen for ON.

This survey, along with the Eating Attitudes Test, and the Whitely Index will be given . to health professionals at the University of Maryland University Hospital and graduate students on the University of Maryland Baltimore campus. Results: We hope to disseminate the survey starting in October 2017 and complete data collection by April 2018. We aim for a sample size of 100 surveys. Conclusions: It is hypothesized that there will be a strong positive correlation between ON and illness anxiety symptoms. Further, it is hypothesized the correlation between ON and illness anxiety symptoms will be significantly stronger than the correlation between AN and illness anxiety symptoms. It is hoped that results from this survey will contribute to the literature conceptualizing ON as a series of symptoms distinct from other ED classifications.

No. 179

Clinical and Sociodemographic Features in Childhood Versus Adolescent-Onset Anorexia Nervosa in an Asian Population

Poster Presenter: Cecilia Kwok
Co-Authors: Victor Kwok, Kelly Ann Zainal, Huei Yen Lee, Shian Ming Tan

SUMMARY:
Background: Onset of anorexia nervosa (AN) is generally in adolescence, however there is a trend of increasing rates in childhood. Childhood-onset AN is often under-recognised and under-treated as it may have an atypical presentation, resulting in an overall worse outcome. This study aims to 1) describe the clinical and socio-demographic features of AN in patients 18 years and below, and 2) compare childhood (onset below 13 years) and adolescent-onset (onset between 13-18 years) AN. Methods: All patients below 18 years of age, diagnosed with anorexia nervosa at Singapore General Hospital between Jan 2003 and Dec 2014, were included. Patients with age of onset below 13 years were categorized as childhood-onset AN while the rest were categorized as adolescent-onset AN. Clinical and socio-demographic information was extracted from casenotes. Results: Overall characteristics: Of the 435 identified patients, 8.3% had onset below 13 years, mean 11.5±1.0 years. The adolescent-onset group had mean age of onset of 15.2±1.6 years. The patients were predominantly female (95.4%) and Chinese (83%). Compared to the general population, a greater proportion of patients stayed in private housing, indicating higher socio-economic background. There was under-representation of Malays and Indians compared to the national ethnic distribution. Comparison between adolescent-onset and childhood-onset groups: The two groups were similar in socio-demographic variables, as well as gender distribution, presenting BMI, amount of weight loss, AN subtype, presence of psychiatric comorbidities and family history. The childhood-onset group had significantly longer duration of illness prior to presentation (4.75 vs 2.62 years), greater frequency of co-morbid OCD (19.4% vs 5.3%), were less likely to report binging symptoms (13.9% vs 26.6%) and were more likely to report teasing as a trigger for AN (58.3% vs 31.6%). The childhood-onset group also had significantly longer duration of inpatient stay (5.97 vs 3.22 weeks), as well as a greater number of total admissions (2.78 vs 1.37). Conclusion: This is one of the few studies looking at anorexia nervosa in children and adolescents in an Asian population. Our results suggest that cultural and socio-economic factors may impact the development or identification of AN in an Asian context. There appears to be a delay in diagnosis of childhood-onset AN, possibly due to an atypical presentation, with a corresponding more unfavorable clinical course.

No. 180

Predictors of Treatment Outcome in Adolescent Outpatients With Anorexia Nervosa

Poster Presenter: Charlotte Jaite

SUMMARY:
Background: This study aimed to determine predictors of treatment outcome in adolescent outpatients with anorexia nervosa (AN). Methods: The sample included 81 adolescent patients (Mage = 16.9, SDage = 1.8) with AN according to DSM-IV. Patients were randomly assigned to either 25 weeks of CBT or 25 weeks of DBT. Before (T0) and after treatment (T1) the Structured Inventory for Anorexic and Bulimic Syndromes (SIAB-EX), the Eating Disorder Inventory-2 (EDI-2) and the Symptom-Checklist-90-R of Derogatis (SCL-90-R) were applied. For each participant body height (m) and body

weight (kg) were measured to calculate the body mass index (BMI) and the BMI percentile. The following baseline variables were examined as possible predictors: age, BMI, duration of illness, subtype of AN, various axis I diagnoses, eating disorder-specific and general psychopathology as well as treatment group (CBT/DBT). Linear regression analyses were conducted to identify the predictors of the BMI and the EDI global score at the end of treatment. Results: A higher BMI (p = .048), a lower age (p = .018), and a lower eating disorder-specific psychopathology (p = .004) were associated with a better outcome at the end of outpatient treatment. The other studied predictors showed no prognostic impact on the treatment outcome. Conclusions: Further research is necessary to investigate whether patients with severe AN might benefit from specific treatment approaches.

No. 181

Comorbid Anorexia Nervosa and Psychosis: Which Came First?

Poster Presenter: Danny Tran, D.O.

SUMMARY:

INTRODUCTION: The incidence of anorexia symptoms is observed in up to 4% of patients diagnosed with schizophrenia (1) while psychosis has been estimated upwards to 13% in patients with eating disorders (2). In cases where symptoms of these two disorders occur simultaneously, it may be difficult to discern if the patient's anorexia is secondary to the psychotic symptoms or whether the patient's malnourished state is the cause of the psychosis. Here we present a case with comorbid anorexia nervosa and psychotic symptoms. CASE: We report a 34 year old African-American female who presented to the intensive care unit on a 7 day petition by her mother for anorexia nervosa, restricting type exhibiting significant muscle wasting, dehydration, and weakness resulting in recurrent syncopal episodes. The patient was emaciated and malnourished, with a height of 5'10 weighing 89 pounds (Body mass index (BMI) of 12.8). She had profound bradycardia (heart rate in the 30's) with hypokalemia. She refused all oral intake. She was started on IV fluids with electrolyte replacement. Psychiatry consulted for anorexia management. According to the patient with collateral from her mother, the patient had been decreasing her food intake for the past 18 months resulting in eating primarily soup and at times a couple bites of her meals each day. She complained of dysphagia, believing she had an obstruction in her throat and esophagus, and complained of chronic sharp abdominal pain. Medical work up was negative for gastrointestinal pathology. She was paranoid of the food presented to her, believing it was unsafe by the people who handled and prepared it. She described "burning sensations" on her skin when presented with food. According to her therapist whom she saw on an emergency basis, the patient had a history of grandiose delusions, believing she was a famous model owning her own fashion line. She has always refused past psychiatric treatment and medications. She was guarded and withdrawn with disorganized and incoherent thought processes. The patient was titrated up on intramuscular olanzapine. Over the following week, her fluids intake improved and she began to slowly eat, at which time we added oral sertraline. Her appetite increased even further and subsequently required management of refeeding syndrome with hypokalemia, hypophosphatemia, and hypomagnesemia. At time of discharge, the patient's electrolytes stabilized, she weighed 115 pounds (BMI of 16.5) and her psychosis was resolved. DISCUSSION This case demonstrates a patient with psychotic symptoms that went untreated for well over a year with prominent delusions resulting in her refusal eat or take medications. The patient responded well to antipsychotics and as her delusions decreased, she ate without difficulty. We illustrate the importance of considering underlying psychosis in patients presenting with eating disorders.

No. 182

Psychogenic Polydipsia in a Female With Anorexia Nervosa: Case Report and Recommendations

Poster Presenter: Jessica Jung-Eun Kim, M.D.
Lead Author: Sofia K. Penev, M.D.
Co-Author: Robert G. Bota, M.D.

SUMMARY:

Psychogenic polydipsia (PPD), characterized by polydipsia and polyuria, has been commonly identified in patients with psychiatric disorders. However, cases describing PPD in patients with

anorexia nervosa are rare. The current literature suggests multifactorial pathogenesis of PPD, involving dysfunctional hypothalamic thirst regulation and subsequent excessive water intake. As anorexia nervosa commonly coexists with depression, anxiety, or OCD, patients may also be taking agents associated with SIADH or anticholinergic side effects like dry mouth, which may further contribute to increased thirst. In addition the pathology of PPD involves compulsive tendencies with the aim of suppressing hunger and controlling appetite. Patients may drink as an attempt to pacify anxiety associated with their body image, eliminate toxins, and maintain a low target weight. Water intake and diuresis may also represent a form of binging and purging, respectively, in a subtype of patients with anorexia. In this case report we support the previously proposed theory that PPD may be a variant of OCD in patients with eating disorders. Our patient in particular expressed emotionally distressing ruminations that were relieved by compulsive drinking behaviors. In this poster we also discuss treatment options for psychiatric conditions concomitant with PPD. While SSRI's have been linked with hyponatremia, mirtazapine seems to be the lowest risk to cause hyponatremia and may be a good option to target associated depression. As patients with anorexia nervosa and OCD display dysfunctional thalamo-frontal circuits and deficiencies in essential fatty acids, fish oil supplementation may also be beneficial in this cohort.

No. 183

A Case of Orthorexia Nervosa With Atypical Features

Poster Presenter: Xiaojing Shi, M.D.
Co-Authors: Douglas Opler, M.D., Chun M. Tong

SUMMARY:

Introduction Orthorexia is defined as a fixation on eating healthy food 1 to avoid ill health. It is not in the DSM-5, but may represent behavioral addiction.2 It has similarities to OCD and eating disorders, with obsessive-compulsive traits: intrusive thoughts about food, health, and contamination. Those with OCD usually recognize obsessions as unreasonable, try to resist them, or perform rituals in response. Orthorexics usually believe symptoms are reasonable.3 They typically have no fear of weight gain. They focus on quality of food instead of quantity and are usually secretive about rules they create for food. It is more common in men, while anorexia and bulimia are more common in women.4 We present a case of orthorexia, which is notable in highlighting a little known illness. Features of the case differ from prior reports. Case Report A 24 year old man with gastritis and no psychiatric history was admitted to medicine for weakness and weight loss. Psychiatry was consulted because he reported a preoccupation with healthy eating for 2 years. He described the motivation to diet as related to worries about health. He endorsed obsessions about protein content, effects of fiber on bowel movement, effects of K+ on cardiac function, and risk of developing diabetes from carbohydrates, despite no problems with glycemic control, bowel, or heart. He lost 30 lbs in 6 months, despite trying to gain weight. BMI was 16.3. He reported anxiety about food so intense that he would wake up to prepare meals for the next day to alleviate anxiety. He would spend great lengths on food preparation. He denied excessive cleaning or preoccupation with order. His mother reported that potatoes, pasta, and ketchup were his primary foods. He found his behavior upsetting, stated that he wished he could change, and "It's killing me." He was referred to follow up with a PCP, psychiatric care, and a dietitian. Discussion: Among eating-related disorders, such as food-related OCD, anorexia, bulimia, and orthorexia, pathological behaviors in anorexia and bulimia are related to how much a patient eats, food-related OCD relates to how the patient eats, and orthorexia involves what the patient eats. Although meeting the definition of an obsessive and pathological fixation on what he ate, so consistent with orthorexia, our patient's presentation differed from the typical reported presentation of orthorexia. While usually ego syntonic, this was not the case in our patient, who had a realization that his behaviors were dangerous. This patient was also forthcoming regarding how he ate, rather than engaging in the typical secretive behaviors previously reported. Conclusion Orthorexia differs from other food-related pathologies, but more data is needed to define diagnostic criteria and the range of presentations, as

well as to determine whether it is a distinct diagnosis or rather a variation on existing diagnoses.

No. 184

Binge Eating and Other Related Eating Psychopathology After Bariatric Surgery

Poster Presenter: Yasmin Nasirzadeh
Co-Authors: Karin Kantarovich, Susan Wnuk, Ph.D., Stephanie Cassin, Ph.D., Raed Hawa, M.D., Sanjeev Sockalingam, M.D.

SUMMARY:
Background: Bariatric surgery results in significant weight loss and decreased burden of comorbidities in individuals with severe obesity. However, a proportion of patients can achieve suboptimal weight loss or weight regain as early as two years after bariatric surgery. Post-operative eating behaviors have been found to contribute to unfavorable weight loss outcomes. We explored the severity of problematic eating behaviors at baseline and yearly up to three years following bariatric surgery. In particular, we investigated the change in severity of binge eating, loss of control eating, emotional eating, and night eating. We also explored the effect of early post-operative eating behaviors on weight loss outcomes. Methods: 844 patients were recruited from the Toronto Bariatric Surgery Centre of Excellence (TBSCE) between 2011 and 2014 as part of the Toronto Bariatric Surgery Psychosocial (Bari-PSCYH) prospective cohort study. Demographic factors, self-report measures of eating pathology (BES, EDE-Q, EES, and NEQ), and weights were collected at baseline and yearly after surgery for three years. Results: There was a significant decrease in eating pathology scores from baseline to the first post-operative year. However, there was a significant increase in binge eating (change in mean score±SD= 0.85±4.71; p=0.002), emotional eating (2.00±13.63; p=0.033), and loss of control eating (1.11±7.01; p<0.001) between the first and second years after surgery and night eating (2.52±8.00; p=0.01) between the second and third years post-surgery. Multiple regression analysis for one year eating measures as predictors of two-year percent total weight loss (%TWL) identified that BES (binge eating scale) score one year after surgery was a significant predictor of two year %TWL (Stn Beta=-0.39, confidence interval (CI) -1.23, -0.16, p=0.012). Conclusion: The severity of maladaptive eating behaviors; specifically binge eating, loss of control eating, emotional eating, and night eating, decreases significantly and remains lower than baseline three years after surgery. However, the severity of these behaviors increases significantly between the first and third post-operative years. Binge eating scale score one year after surgery was the only measure to predict worse weight loss at two years. Our study provides further evidence that maladaptive eating behaviors can continue after bariatric surgery and can be detrimental to weight outcomes. Further prospective studies with sufficient power are required to explore long-term post-operative eating pathology and weight outcomes including weight regain beyond two years. This research may inform appropriate post-operative monitoring and referral to mitigate weight regain.

No. 185

Anosmia, Anorexia, and Anhedonia: A Case Study

Poster Presenter: Alicia E. Phillips, D.O.
Co-Author: Mercedes Driscoll, M.D.

SUMMARY:
There are many factors that contribute to the development of anorexia nervosa (AN), including female gender, genetics, anxiety, depression and perfectionism. Anosmia, while not commonly thought of as a predisposing factor for eating disorders, has been associated with decreased perceived quality of life. Impaired sense of smell and taste have previously been demonstrated in patients with both anorexia and bulimia. Here we present the complicated case of a depressed 45-year-old female with a body mass index (BMI) of 11.7 who has anosmia secondary to a motor vehicle accident (MVA) which also resulted in a subsequent traumatic brain injury (TBI). Prior to the MVA in her early 20s she did not have mood symptoms or disordered eating behaviors. She was evaluated by the psychiatric consult service while hospitalized on the medical service for severe hypokalemia (K <3.0) secondary to restrictive eating behaviors . Recently , the patient had become increasingly selective about her food choices, often eating the same type of food, such as a hamburger, for every meal for a prolonged period of time. During her hospitalization, the patient expressed ambivalence about the severity of

her medical conditions. She did however express significant frustration about her anosmia citing it as a reason as to why she has difficulty experiencing pleasure while eating and in other areas of life. In addition to anorexia, the patient also suffered from depression (most recent PHQ-9 score was 24/27). She had recently re-engaged with outpatient behavioral health prior to her current admission, however continued to adamantly deny that she also has an eating disorder. Although there were likely many factors contributing to this patient's anorexia and depression, we propose that her anosmia was a significant contributor to both her depression and her anorexia. Treatment should take into consideration addressing how loss of smell contributes to her perceived lower quality of life.

No. 186

Prevalence of Substance Use Comorbidity in Individuals With Eating Disorders: A Systematic Review

Poster Presenter: Anees Bahji, M.D.
Co-Author: Mir N. Mazhar, M.D.

SUMMARY:
Objective: The comorbidity of substance use disorders (SUDs) and eating disorders (EDs) has frequently been reported over the past four decades, however, there has been no recent synthesis of the literature. The objective of this study was to systematically review the literature on the prevalence of comorbid SUD in individuals with ED, and to report rates of lifetime prevalence. Method: A search of 6 databases (EMBASE, CINHAL, Medline, PubMed, Cochrane, and PsycINFO) was conducted targeting articles on the epidemiology of comorbid SUDs in individuals with EDs, in particular, reported rates of prevalence. The review was performed in accordance with PRISMA guidelines and was limited to studies using standardized or validated criteria to assign ED and SUD diagnoses, published between 1980 and 2017. Results: A total of 43 studies fulfilled inclusion criteria and were included in the study. This review indicates that the prevalence of SUD is higher in individuals with bulimia nervosa (BN) than in anorexia nervosa (AN), and highest amongst those with both disorders (ANBN). Discussion: A limitation to the study was that none of the included studies investigated the new DSM-5 feeding and eating disorders, which warrants attention in future studies investigating the epidemiology of feeding and eating disorders. Several mechanisms explaining the eating disorder-substance use/abuse link are considered, and suggestions for future research are made.

No. 187

Efficacy and Speed of Response of ECT for Unipolar Versus. Bipolar Depression: Systematic Review and Meta-Analysis

Poster Presenter: Anees Bahji, M.D.

SUMMARY:
Objective: Pharmacological efficacy for bipolar major depression (BP) differs from unipolar major depression (UP). In BP, response to treatment with antidepressants is controversial. Whether response to electroconvulsive therapy (ECT) differs between UP and BP remains unclear; in any case, ECT remains a relatively underused treatment modality. Therefore, this systematic review investigates the relative efficacy of ECT in both types of depression. Methods: Relevant cohort studies were identified from a systematic search of the PubMed, Medline, PsycINFO, EMBASE, CINAHL, and Cochrane electronic databases and applying the Preferred Reporting Items for Systematic Reviews and Meta-analysis (PRISMA) guidelines. Ultimately, seventeen studies were included in this meta-analysis. Results: The overall response rate for depression was 59.6% (n = 1193/2001) and the overall remission rate was 44.2% (n = 570/1290). In UP, the response and remission rates were 58.9% (n = 889/1510) and 41.0% (n = 374/913), respectively. In BP, the response and remission rates were 61.9% (n = 304/491) and 52.0% (n = 196/377), respectively. Pooled odds ratios (OR) and 95% confidence intervals (CI) were calculated using random-effects meta-analysis. Similar rates of response to ECT were found in patients with unipolar and bipolar depression (OR = 0.93, CI: 0.73-1.2, p = 0.54), whereas remission rates with ECT were significantly higher in patients with bipolar vs. unipolar depression (OR = 0.73, CI: 0.56-0.96, p = 0.027). Conclusion: Response rates to ECT appear to be equally effective for both UP and BP. However, remission rates are higher in BP, which may be helpful in informing future clinical decision making for patients with refractory mood disorders.

No. 188

Choosing Wisely: An Audit of Urine Drug Screen and Blood Alcohol Testing in Emergency Psychiatry Patients

Poster Presenter: Anees Bahji, M.D.

SUMMARY:

Background: Exposure to illicit drugs and alcohol is a major cause for visits to the emergency department (ED). Urine drug screens (UDS) and blood alcohol levels (BAL) are frequently ordered, however, the utility of these tests in diagnosis and management remain unclear. Methods: ED patients with a mental health or addictions (MHA) chief complaint were retrospectively reviewed over a 3-month period. UDS and BAL ordering and results, patient demographics, medical and psychiatric history, presenting diagnosis, treatment plan, and disposition were extracted and analyzed. Results: our sample included a total of 323 patients. 60 received BAL and 92 received UDS. The main indications for these tests were "history of substance use" and "rule out substance-induced psychosis". BAL and UDS testing did not impact the management of all but two (1%) patients. 35% of patients who received these tests did not receive addictions-specific treatment. Conclusion: roughly one third of the sample received UDS or BAL testing, and for the majority of tests, the documented rationale was inappropriate. Our results suggest that these tests have limited utility in this setting. Increased education on the ordering of these tests could reduce unnecessary testing.

No. 189

Successful Mitigation of PTSD and Fibromyalgia Symptoms With rTMS: A Safer Alternative?

Poster Presenter: Andrew Buchholz
Co-Authors: Tim Heilmann, Sandeep Saran

SUMMARY:

Background: Repetitive Transcranial Magnetic Stimulation (rTMS), initially developed as a research and diagnostic tool, received FDA approval for the treatment of depression in 2008. There have also been promising results for the treatment of chronic pain conditions. Here, we present a case of a military member with severe depression and chronic pain treated with rTMS as pharmacologic options were limited by coexisting polypharmacy. Clinical Case: The patient is a 59 year old Caucasian male was referred to an outpatient psychiatry service at an academic medical center for depressive, posttraumatic, and pain symptoms stemming from his recently diagnosed fibromyalgia. Baseline objective symptom scores included Brief Pain Inventory (BPI) impact score of 7.6, Fibromyalgia Impact Questionnaire Revised (FIQR) composite of 59.3 (overall impact score of 9), PHQ-9 of 16, and Zung Depression Scale of 55. Considering the failed treatments with two SSRIs, three SNRIs, and one TCA, the decision was made to try rTMS. His Depression, PTSD, and pain scores were tracked. Treatment: No changes in medications or psychotherapy occurred. 30 sessions of rTMS using the NeuroStar TMS Therapy® system using standardized left dorsolateral prefrontal cortex depression protocol were given over 8 weeks. Patient's depression rating scale scores demonstrated a trend towards remission of MDD, with PHQ-9 scores dropping as low as 12 at the end of week 7, but rising back to 16 at the conclusion of the final treatment. The patient's Zung Depression Scale scores fell below MDD threshold at 48 (MDD ? 50). The patient's PTSD rating scale, the PCL-5, fell below the threshold of ? 38. With regard to his pain scales, his BPI impact score fell to 6.8. His FIQR impact scale fell from 14 to 9 and his FIQR composite score fell from 59.3 (severe fibromyalgia) to 40.6 (mild fibromyalgia). Conclusion: To our knowledge, this is the first report in the United States Military of the potential for rTMS to treat chronic pain. rTMS creates a magnetic field to generate action potentials at a point in the left dorsolateral prefrontal cortex noted to be hypoactive in depression. Research suggests that rTMS has an efficacy on par with SSRIs – but with fewer side effects and drug interactions. Although the mechanism of treatment with rTMS for chronic pain conditions is not yet known, it has been posited that rTMS may stimulate endogenous opioid release. Other researchers theorize that it is the treatment of depression that leads to pain relief and reduction in functional impact. Studies in the European literature have noted pain relief in patients independent of depressive symptom control – similar to our patient. The use of rTMS in medicine has the potential to

safely and affordably treat chronic pain in military members while reducing the use of opiate and non-opiate analgesics – which carry risk of dependence, morbidity, and mortality.

No. 190

Dead Man Walking: A Case of Coexisting Cotard and Capgras Syndromes Successfully Treated by ECT

Poster Presenter: Ashhar Bhurgri, M.D.
Co-Authors: Ahsan Syed Khalid, M.D., Raymond Faber, Usman Ghumman

SUMMARY:

The Capgras delusion is a delusional misidentification syndrome characterized by the belief that an imposter has been substituted for someone close to the believer. The Cotard delusion is a rarer condition wherein a person believes that they or their internal organs are dead or rotting. Both have been associated with various psychiatric and neurological conditions. ECT has been used to successfully treat these disorders individually. We present what may be the first case report of coexisting Capgras and Cotard syndromes which resolved with a course of ECT. Our patient, 72-year-old female with a history of bipolar disorder, was hospitalized for the third time in less than one month for worsening depression. She had nihilistic delusions of being dead (Cotard's syndrome) when she first presented. After one week her daughter reported that the patient had told her that she was not her real daughter but an imposter (Capgras syndrome). The patient added that this imposter looked, sounded and had the same jewelry as her daughter. She was emphatic in insisting this was an imposter. After an olanzapine trial failed, a course of bilateral ECT was initiated.Both Cotard's and Capgras syndromes as well as mood symptoms resolved within 2 weeks of ECT treatments. To our knowledge, this is the first reported case of successful ECT for combined Cotard's and Capgras syndromes. We consider both Cotard and Capgras as severe delusional illnesses and therefore recommend that ECT should be considered as the first-line treatment for them over antipsychotics, if clinically possible.

No. 191

Every Second Counts: A Retrospective Case Series on Patients Who Underwent Electroconvulsive Therapy in Medical City Philippines September 2015–2016

Poster Presenter: Joyce Ann N. Maglaque, M.D.

SUMMARY:

ECT remains to be a mainstay in the arsenal of treatments for psychiatrists, especially for patients who are deemed treatment resistant. However much is yet to be known regarding the practice of ECT and if there are nuances dependent on certain patient factors, such as age, gender, maintenance medications, psychiatric diagnosis, history of psychopathology and ECT lead placement. To determine these, this study employed a retrospective case series, which utilized chart reviews of patients given ECT at The Medical City from September 1, 2015 to August 31, 2016. After extensive inclusion and exclusion criteria were employed, seven out of the 13 patients given ECT that year were included for this study (n=7). This was comprised of: three (n=3) with MDD, two (n=2) with Bipolar Disorder MRE Depressed, two (n=2) with schizophrenia spectrum disorders. For these cases, they were all initially recommended to undergo 6 ECT sessions. All underwent the same anesthetic technique, performed by the same anesthesiologist. Comparison of their course during treatment was obtained through chart review and through recorded DSM-5 symptom checker accomplished on their admission, after 4th ECT session, after the last ECT session and 24 hours before discharge. Results describe that only cases with MDD who were in their early adulthood (n=2) showed reduction of symptoms 24 hours after the 4th ECT session and did not require further sessions or any changes in the placement of the ECT leads. In contrast, two (n=2) of the cases who were women in their late adulthood required a shift from an initial unilateral ECT to bilateral ECT after no improvement was noted in their 4th session, thereby requiring more sessions than planned. Cases with other diagnoses (n=4) also required more sessions than initially planned and did not show improvement in their symptom checkers 24 hours after the 4th ECT session. Further comparisons in the course of symptoms, as well as the history of each case and overview of their hospital stay, are detailed in the results of this study. Findings and how each case compares with current

literature on the understanding of ECT and factors such as age, gender, diagnosis, history of psychopathology, lead placement, were further explored in the discussion. Because there is little research on the practice of ECT in the country, it is recommended for future researchers to compare symptomatology of patients and their clinical course during the duration of ECT treatment for a longer period of time and with a larger sample size.

No. 192

Electroconvulsive Therapy in a Patient With a History of Significant Mandibular Trauma Secondary to Self-Inflicted Gunshot Wound

Poster Presenter: Maria E. Aguilar, M.D.
Co-Authors: Enoch Barrios, M.D., Robert J. DiFilippo, D.O., Shruti Mutalik

SUMMARY:
Ms. L., a 56-year-old Caucasian female with a past psychiatric history of Post-Traumatic Stress Disorder, and Depression with multiple prior suicide attempts, most recent 1 year ago via gunshot wound to mandible, presents to the psychiatric consult service as transfer from outside facility for trial of Electroconvulsive Therapy in setting of depression with catatonic features. Patient initially presented to outside facility two months prior to transfer with complaints of dizziness, hypotension, headache and diarrhea. During hospitalization, depressive symptoms progressed to severe catatonia retarded type, resistant to benzodiazepine treatment. Bush-Francis rating scale scores ranged from 13 to 25. Symptoms initially improved with low-dose Ativan. Given severity of symptoms, to include patient endorsing suicidality, she was transferred to facility with ECT capabilities. Upon presentation to consult service, catatonia had improved and she was ambulating on own. Physical exam was significant for facial asymmetry and micrognathia due to underlying bone destruction. Mandibular radiographs revealed traumatic destruction of the left mandibular body and right maxillary dental prostheses were noted. Initial PHQ9 prior to ECT was 26 [Extremely Difficult]. After two treatments, patient's PHQ9 was 7 [Somewhat Difficult] and she was denying suicidality. In preparation for patient, there were limited studies regarding placement of ECT leads in patients with facial trauma, specifically trauma from self-inflicted gunshot wounds. As a result of the trauma, the right mandibular bone was completely destroyed, warranting prosthetics. Unfortunately, her prosthesis became infected, resulting in additional scarring and failure of the prosthesis. ECT leads were place in modified bilateral position to ensure rapid improvement in depression and suicidality, and also to decrease the amount of stimulus provided to the right temporalis and right masseters. Left lead was placed over the left temple and right lead was placed medial to the right temple. We discuss the importance of providing ECT to those with atypical anatomy and alternative lead placement in this population.

No. 193

Baclofen Withdrawal-Induced Psychosis: A Case Report and Review

Poster Presenter: France M. Leandre, M.D.
Co-Author: Almari Ginory, D.O.

SUMMARY:
Patient is a 47 year old Caucasian male with a psychiatric history of anxiety who presented to the emergency department with complaints of spontaneous twitching. It was later discovered that there were 116 tablets of Lyrica 100mg, 100 tablets of baclofen 10mg and 11 tablets of Omeprazole 20mg missing. The patient was intubated for 1 day and subsequently extubated. On day 3 of his admission, he became paranoid and started refusing medications. On day 4 he developed visual and auditory hallucinations, thoughts blocking, and worsening paranoia. He had a CT of the head which was negative and his labs were within normal limits. As no medical cause for his symptoms were found, he was admitted to the inpatient psychiatric unit and restarted on Baclofen as well as escitalopram, trazodone, and hydroxyzine. His symptoms resolved once baclofen was restarted and he was discharged home after 5 days. Baclofen is primarily used for muscle spasms. It's mechanism of action include activation of the GABAb receptors and sudden discontinuation can lead to hallucinations, altered mental status, and seizures. Others symptoms of withdrawal from baclofen include hypertonia, hyperthermia, tachycardia, and restlessness. Patient should be tapered off of this medications slowly especially after long-term use. For patients, it is

important to monitor for withdrawal from medications. In this patient's case, his symptoms were attributed to a primary psychiatric illness as the team had not associated his refusal to take medications with withdrawal symptoms.

Improving Cardiometabolic Monitoring for Patients on Antipsychotic Medications: Implementing a Cardiometabolic Order Set in the Outpatient Setting

Poster Presenter: Frozan Walyzada, M.D.
Co-Authors: Pankaj Manocha, M.D., Charles Rodolphe Odom, M.D., Raminder Pal Singh Cheema, M.D., Ashaki Martin, M.D., Monika Gashi, M.D., Sasidhar Gunturu, M.D., Wen Gu, Ketki Sharadkumar Shah, M.D., Panagiota Korenis, M.D.

SUMMARY:
The American Psychiatric Association (APA) has implemented guidelines on how patients that are on antipsychotics should be monitored as research has shown us that people that suffer from serious and persistent mental illness die 25 years earlier than the general population. While weight and Body Mass Index (BMI) are important data points to collect, other metabolic factors should also be considered such as Hemoglobin A1C, a lipid panel, and fasting glucose. In order to measure how well we were doing in our outpatient department, we looked at 2826 outpatient records to see if how much of this data was collected. What we found was Hemoglobin A1C was screened 30% of the time, fasting glucose 52% of the time and a lipid panel was screened 38% of the time. When thinking about ways that we could improve the data collection, aside from provider education, we had to find a way to simplify the process. The answer? Creating an order set. This way one step would have all the relevant components thus ensuring that a test is not forgotten and not adding additional time that it would take to place all the orders individually. To see how much we improved, we will be looking at the outpatient department again for the year 2017 and comparing those values. What we anticipate is that there will be an improvement based on what we saw from a small snapshot from January to April 2017.

No. 195

Psychological Distress Affect Almost All Items of the WHOQOL-BREF and Mediate the Effects of Stigma Among Opioid-Dependent Individuals

Poster Presenter: Kun-Chia Chang

SUMMARY:
Background: Both stigma and psychological distress are associated with the overall quality of life (QOL). The objectives of this study are to explore how these two factors affect the different domains and facets of QOL, and the possible mediation effect between psychological distress and self-stigma among opioid dependent individuals. Methods: We interviewed 268 treatment-seeking opioid dependent individuals using the brief version of the World Health Organization Quality of Life instrument (WHOQOL-BREF), the Self-Stigma Scale-Short (SSS-S), the Chinese Health Questionnaire-12 (CHQ-12) and the Opiate Treatment Index (OTI). We constructed multiple linear regression models to determine if the SSS-S and CHQ-12 predict the WHOQOL-BREF scores and tested the potential mediation effects of psychological distress (as assessed by the CHQ-12) between SSS-S and WHOQOL-BREF. Results: The CHQ-12 score was predictive to the scores of the four domains and almost all facets of the WHOQOL-BREF except the item of "Dependence on Medical aids". The significant predictive effects of the SSS-S score on 14 of the 26 facets of the WHOQOL-BREF were reduced to 5, with three in the social domain, after the adjustment of the CHQ-12 score. Psychological distress completely mediated the relation between Self-stigma and physical, psychological, environmental domains, and partially mediated the relationship between self-stigma and social QOL domains. Self-stigma was still significantly associated with social QOL. Conclusions: Psychological distress has a large impact on QOL among treated opioid users. Furthermore, it appears to be a core element in reducing the negative effects of self-stigma on aspects of QOL.

No. 196

Patient Elopement: A Deeper Look at the Aftermath

Poster Presenter: Gina Schlueter
Co-Author: Rana Elmaghraby, M.D.

SUMMARY:
Elopements from secured inpatient behavioral

health units are a rising and dire concern in the medical community. These events can be detrimental to a patient's care, traumatic to staff, and costly to administration. Not only can they lead to distrust from the patient's family, but also disrupt any provider-patient relationship. In fact, elopements are such significant events that "lack of supervision of cognitively impaired individuals with known elopement risk" is considered a trigger for Immediate Jeopardy investigation based on guidelines from the Centers for Medicare and Medicaid Services (CMS).1The repercussions of elopements from inpatient behavioral health units vary between facilities, staff, and most importantly patients. These events are individualized and consequently have a wide variety of effects on the patient and those around them. This poster presents a case of a patient experiencing symptoms of what will most likely be a lifelong psychiatric illness, who was being treated on a secure inpatient unit. In an ideal world, the treatment would have consisted of care coordination, family and patient education, and a plan for consistent follow up. Yet, none of these things can be completed if the patient unexpectedly leaves the unit. This case is a notable example of the effects elopement can have on a patient, their family, the treatment team, and the community. Beyond the effects for this one patient, elopements as a whole are serious adverse events. This poster highlights the significance of preventing elopements and explores mechanisms to achieve that, which is an area in need of improvement.

First-Episode Psychosis With History of Chronic Cannabis Use Successfully Treated Using ECT Where Other Antipsychotic Treatments Were Refractory
Poster Presenter: Tyler A. Curry, D.O.
Co-Authors: Ashish Sharma, M.D., Matthew K. Egbert, M.D.

SUMMARY:
Ms. A, a 21-year-old Caucasian female with no significant past psychiatric history presented to the emergency department with new onset psychosis. Her symptoms included delusions of pseudocyesis, auditory command hallucinations, and paranoia. She was transferred to inpatient psychiatric unit for further care. She was a college student living in a dorm. Her family reported a history of chronic and heavy cannabis use. Her significant pre-morbid cannabis use obscured the natural history of the disease processes, so several differential diagnoses were kept in mind including first onset psychosis, substance -induced psychosis, schizophrenia and schizoaffective disorder. During her hospitalization, several treatment modalities were tried including anti-depressants and several different antipsychotic medications with no response. Due to the treatment refractoriness of her psychosis, ECT was considered. She demonstrated significant improvement in her symptoms with ECT. After undergoing ten ECT treatments, the patient made remarkable progress and as per her parents, she was 95% back to her baseline level of functioning. We propose the hypothesis that ECT is a viable and effective option when confronted with a case of treatment-refractory psychosis with history of chronic cannabis use.

No. 199
Psy-Q.Com: A Pilot Online, Collaborative Question Bank for Psychiatry Education
Poster Presenter: Zachary Grunau
Co-Authors: John Torous, M.D., Robyn P. Thom, M.D., Fremonta L. Meyer, M.D., Robert Joseph Boland, M.D.

SUMMARY:
Background: Medical students are increasingly preferring online and electronic educational resources, and in many cases prefer these sources to physical textbooks. (1) High-quality question banks are a frequently used resource. Students use question bank apps often during third year, but use apps less frequently during their psychiatry clerkship, possibly due to an absence of highly-rated psychiatric educational apps. (2) Studying through using question banks is not just student preference; use of high quality question banks have been shown to be associated with higher standardized board exam scores. (3). Additionally, collaborative question bank creation has been shown to be an effective method for medical education. (4) Therefore, we have created a free online and collaborative question bank specifically for psychiatry education.

We have initially populated it with 100 faculty-reviewed question and answers. However, as students use the site, they will be able to submit their own questions and answers, which will then be reviewed by faculty and added to the bank. We will pilot the site through a study in one medical school. Our study will passively observe student use of the site, while also utilizing a brief end-of-experience survey. This project will add to the very limited data concerning medical student perceptions and preferences concerning electronic resources specific to the psychiatry clerkship and aid course directors and medical educators in understanding student perceptions of the current state of clinical psychiatry supplemental educational tools. Additionally, we hope to create a portal through which students, residents, and fellows can collaborate and learn. Methods: This is a simple observational study. Students will be offered access to an educational website and we will observe website usage through passive data collection. We will also learn about usage through an optional exit survey. Results: Pending completion of 6 month study period. Conclusions: Pending completion of 6 month study period and data analysis.

No. 200

Quetiapine-Induced Bruxism and Its Management

Poster Presenter: Nigila Ravichandran, M.B.B.S., M.Med.
Co-Author: Han Yang Khiew, M.B., M.B.B.S., B.A.

SUMMARY:

Objective: To present a rare case of Quetiapine-induced bruxism in a patient with Organic Brain Syndrome and Mood Disorder following a road-traffic accident Methods: Case report and review of literature Summary and Results: A 56-year-old man was admitted for relapse of Depression and anxiety with passive suicidal thoughts. He had suffered bilateral sub-arachnoid haemorrhages, cervical spinal fractures and left rib fractures following a road-traffic accident in May 2016. This admission lasted 1 month and 24 days, where several medications and anti-psychotics were used to stabilise his mood. He initially received a combination of Fluvoxamine, Risperidone and Sodium Valproate to stabilise his mood. Due to minimal improvement, Risperidone was cross-tapered with Haloperidol. However, he developed tremors (hands, arms and body) and progressive worsening of oral tardive dyskinesia despite being on anti-cholinergics and decision was made to switch to an atypical antipsychotic. During this time, no evidence of bruxism was observed. He was started on Quetiapine 50mg BD, but after nine days, he developed bruxism, both teeth grinding and clenching of the jaw. The teeth grinding was present only during the daytime, and increased gradually in intensity for the next few days despite discontinuation of Quetiapine, until he had difficulty falling asleep. He had no known prior conditions or dysfunctions of the tempero-mandibular joint, or other dental conditions. He was started on 1 tablet of Anarex (Paracetamol 450mg, Orphenadrine Citrate 35mg) for its muscle relaxant effects and after 5 days, there was slight improvement in his bruxism. Anarex was increased to 4 tablets per day with Clonazepam (0.5mg), which further improved his bruxism. Eventually the bruxism was not noticeable by the patient and others around him. Currently, the treatment for bruxism (from any cause) is aimed at alleviating muscle discomfort, prevention of dental wear and reduction of teeth grinding sounds. Reduction of dose or change of medications may resolve the problem. However in this case, the bruxism persisted despite discontinuation of the agent. Conclusion: Currently, there is no universal treatment (at least pharmacologically) for bruxism. There are only a few case reports in literature which have demonstrated a reduction in or complete cessation of bruxism arising from psychotropic agents. Use of agents like propranolol, clozapine and gabapentin has been reported. Non-pharmacological interventions such as use of a mouth-guard to prevent dental wear have also been implemented.

No. 201

Using Simulation to Achieve Integrated Care (IC) Competency in Medical School: The Getting to Know Patients' System of Care (GPS-Care) Experience

Poster Presenter: Rida Hashmi
Co-Authors: Sanjeev Sockalingam, M.D., Zarah Chaudhary, Maria Mylopoulos, Andrew Lee

SUMMARY:

Background: With emerging evidence and adoption of the integrated care model (ICM), there has been a call to introduce IC and medical psychiatry(MP) training earlier in undergraduate medical education(UME). Currently, few education modules on IC have been fully described and evaluated within preclinical(PC) years. The American Psychiatric Association Council on Medical Education and Lifelong Learning advocates for development of simulation experiences that emphasize MP co-morbidity, beginning in PC training. Purpose: We describe analysis of integration of an MP competency framework into a novel simulation experience for first-year medical students; GPS-Care, to learn about foundational competencies of IC for patients with co-occurring physical and mental illness. Methods: The GPS development team, consisting of educators, family physicians, psychiatrists, and geriatricians, created 5 unique case simulations. Each contained 5 health care provider (HCP) stations that reflected a unique patient care experience within this simulated health care system. Students were divided into groups of 3, 1 role-playing the patient and 2 playing care givers. In groups of 3, a total of 204 students navigated through 5 simulated visits with different HCPs. Students were provided with a longitudinal patient narrative describing the progression and impact of physical and mental illness on the patient and the care givers. An MP reviewer assessed how many of 9 MP competencies were likely achieved within each station of all five streams. Results: Overall the GPS care experiences addressed 7 of 9 competencies from our previously developed UME IC competency framework. The competencies mapped the most were: 'Integrates content knowledge of medical and psychiatric illnesses to patients with co-occurring mental and physical health conditions' and 'Advocates for the complex health needs of patients'. The competencies least likely to be achieved were: 'Identifies ambiguity and seeks help in managing complex patient health needs within inter-professional teams 'and 'Recognizes their own bias and the biases of those in their system of care towards psychiatric patients (supervisor or collaborating healthcare professionals) and identify strategies to manage these biases'. Discussion: We demonstrate a process by which we operationalized a competency framework for IC in UME at the program level. GPS care provided students with an opportunity to approach real-world situations where care issues emerge for patients with both physical and mental illness. Students could achieve several UME IC competencies through GPS Care through a scalable simulation experience for all students. Through mapping of competencies, additional IC curricula can be developed to address the remaining IC competencies not achieved through GPS Care. Conclusion: The following study provides a framework for integrating the ICM early in medical school training informing future curriculum development.

No. 202

Psychiatric Manifestations of Lead Poisoning

Poster Presenter: Sabahat Khan, M.D.
Co-Authors: Rajesh R. Tampi, M.D., M.S., Silpa Balachandran, M.D.

SUMMARY:

Introduction: A 35-year-old African-American male presented to the clinic for evaluation of depression and anxiety. Patient stated that he had been experiencing difficulties with concentration and memory. He also complained of sleeping difficulties, depressed mood, and recurrent anxiety attacks. Upon further investigation, it was discovered that the patient had a history of high blood pressure, headaches that had been diagnosed as tension headaches, gastric pain, and microcytic anemia. Patients history also indicated 2 previous suicide attempts in his early 20's. During the encounter, the patient had some difficulty understanding the standardized depression scale and GDS-7 questioners and needed simplification of the questions. Patient also had some difficulties articulating responses at an adult level. Considering his presentation of mood disorder and his past medical history, as well as, a possible learning disability, we considered lead poisoning as a likely underlying cause. Blood lead levels (BLL) were ordered which revealed a BLL of 19 µg/dL. Objective: In this poster, we discuss the psychiatric manifestations of lead poisoning and the importance of early detection and treatment. Method and Results: We conducted a literature review assessing the psychiatric manifestations of lead poisoning. It was revealed that lead exposure can result in

anxiety, depression, phobias, along with declines in intelligence, memory, and comprehension. Early exposure to lead has also been linked to development of antisocial behavior. Timely chelation treatment and removal of exposure has shown to prevent or reverse the effects of lead toxicity. Conclusion: Acute and chronic exposure to lead can lead to significant psychiatric manifestations depending on the level of exposure. Early detection and treatment may aid in the reversal of post-toxicity sequalae in children and adults. For our adult patient, he likely had childhood exposure to lead that went untreated and he continues to have exposure as an adult. It is recommended the patient remove the source of lead exposure and continue medical and supportive treatment for his depression and anxiety.

Cause of Neuropsychiatric Manifestations in Systemic Lupus Erythematosus

Poster Presenter: Sabahat Khan, M.D.
Co-Authors: Rajesh R. Tampi, M.D., M.S., Poorvanshi Alag, M.D.

SUMMARY:

Introduction: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune inflammatory disease process which affects multiple organ systems and can differ in presentation from patient to patient. Neurological manifestations are one of the common occurrence in SLE and can be seen in 25 to 75% of the patients but they can be difficult to diagnose due to their varied presentation. Patients can present with depression, anxiety, psychosis, cognitive defects, or dementia. Objective: In this poster, we aim to explore the possible causes of neuropsychiatric involvement in SLE in order to better understand the mechanism of the disease process. Methods and Results: We conducted a systematic review, which revealed studies have demonstrated that vascular abnormality, inflammation, and autoantibodies play a significant role in development of neuropsychiatric symptoms of SLE. Analysis of data on serum and CSF antibodies in patients with neuropsychiatric SLE (NPSLE) has revealed that these patients had elevated levels of lupus anticoagulant (LA), anticardiolipin (aCL), antiribosomal P antibodies, antiphospholipids (APL), and antineuronal antibodies compared to patients that did not present with neuropsychiatric symptoms in the presence of SLE. Some prospective studies have proposed secondary factors to be the cause, these factors include: infections due to immunosuppressive therapy, hypertension, complications of other organ system failure, and effects of SLE treatment with corticosteroids. Conclusion: The exact cause of NPSLE is unknown but there is a strong emphasis on the connection between increased levels of various antibodies and the development of neuropsychiatric symptoms. Secondary causes must also be taken into consideration and treated accordingly. Since NPSLE is a diagnosis of exclusion, lab and imaging studies need to be conducted to rule out other causes. Treatment will vary depending on the presentation and the cause of neuropsychiatric symptoms.

No. 204

Feasibility of Mobile Health Technologies for Detection of Common Mental Health Disorders, Treatment Engagement, and Adherence to Care in Nepal

Poster Presenter: Anvita Bhardwaj
Co-Authors: Sauharda Rai, Kiran Thapa, Prasansa Subba, Renasha Ghimire, Chaya Bhat, Eric Green, Brandon Alan Kohrt, M.D., Ph.D.

SUMMARY:

A global trend to address the burden of mental illnesses is to use lay community health workers (LCHWs) to identify persons with mental illness in the community, help them initiate care and adhere to treatment. Innovative digital mobile health (mHealth) technologies can be used to facilitate involvement of LCHWs in mental health services in low resource settings. mHealth applications in healthcare have shown promising clinical results. To explore the potential for mHealth technology use by LCHWs in Nepal, we conducted a study to assess the feasibility, acceptability, and utility of two technologies: (1) home sensing devices to assist in detecting mental illnesses and promoting adherence to care, and (2) a SMS (text messaging) treatment engagement system used to refer persons with mental illness in the community to primary care services and reduce delays in seeking treatment. The SMS system was designed to refer persons affected

by depression, alcohol use disorder, psychosis, post-traumatic stress disorder, epilepsy, antenatal depression, postnatal depression, and suicidal behavior. Before implementation of the mHealth applications, qualitative interviews were used to gauge acceptability, feasibility and utility of the application. Fourteen key informant interviews (KIIs) with LCHWs, 5 focus group discussions (FGDs) with LCHWs (n=31), 6 KIIs with community members, and 2 FGDs with community members (n=12) were conducted. Participants watched videos in which Nepali LCHWs used the technologies (videos are available at https://tinyurl.com/y7aa65m3). Participants scored devices according to standardized criteria for acceptability, feasibility and utility. We assessed these criteria using anchored vignettes, a qualitative method designed for low literacy populations. Qualitative findings demonstrated that home sensing devices are seen as feasible and acceptable given proper cultural adaptation and have high utility. For treatment engagement, we adapted the paper-based Community Informant Detection Tool (CIDT) to employ a SMS referral and tracking system, referred to as mCIDT. Forty LCHWs and 8 primary care workers were trained on the mCIDT platform. Results demonstrated an increase of approximately one new referral per week using the SMS system. Barriers to use of mCIDT were illiteracy among LCHWs, lack of familiarity with mobile phone functions, lack of recognition of the community burden of mental illness, preferences for other cadres of workers to take on the tool, and lack of mental health-trained primary care workers to receive referrals. Acceptability and feasibility of mHealth technologies and devices would be enhanced through improvements in technological literacy and transparency of data collection and data use in the health system, as well as increased awareness of the burden of mental illness in local communities. This study was supported by The Jacobs Foundation (Zurich, Switzerland) and the Duke Global Health Institute (Durham, USA).

No. 205

Preliminary Findings: Systematic Review Study of Schizophrenia App Usability and Engagement

Poster Presenter: Julia Tartaglia
Co-Author: John Torous, M.D.

SUMMARY:
Background: With the recent popularity of smartphone apps for schizophrenia, there had been a rise research studies examining the feasibility and acceptability of these novel monitoring and treatment tools. However, there is little literature examining the design, usability, and engagement features of such apps, which are important factors to determine their clinical feasibility. We conducted a systematic review of all studies reporting clinical, usability, and/or engagement outcomes of smartphone applications targeting patients with schizophrenia as the end-user (n=>1, SZ%=>50%). Methods: An electronic database search of PubMed, PsychInfo, Cochrane, and the Web of Science was conducted on June 26, 2017, which produced 186 results. Studies were systematically screened two independent reviewers, from which 14 eligible articles were identified. A systematic analysis was conducted based on pre-determined criteria that assessed the category of app, mobile features included, and outcomes reported (subdivided into clinical, usability and engagement outcomes). Papers were further compared based on study protocol, including study setting (lab or environment) and length of intervention. Results : Of the 14 studies, we identified 10 unique apps. The most common app category was symptom self-assessment tools and remote monitoring tools (8 apps), followed by clinical interventions (4 apps), on-demand health literacy (2 apps) and prescription-management tools (2 apps). Most apps utilized mobile features that required “active” user input., such as data entry through questionnaires using a sliding touch scale (used by 6 apps). “Passive” data collected utilized the following mobile features: mobile global positioning system, or GPS (3 apps), microphone (2 apps), accelerometer (2 apps), and light sensors (2 apps). All of the 7 papers that measured usability outcomes reported positive ease of use (80% satisfaction across scales reported). Ten papers measured engagement outcome metrics. Across apps, participants engaged with the app an average of 75.7% total days during the study period and responded to an average of 69.5% of prompts. Seven papers reported compliance metrics (defined as % of participants completing >33% of data points), which ranged from 40% to 88%. Study lengths varied

between 1 day (single use usability analysis) to 6 months. Conclusion: Though the data is limited on schizophrenia apps, positive usability outcomes reported suggests that smartphone interventions are both usable by patients with schizophrenia and that most participants are compliant with protocols. Although researchers are beginning to analyze app design, usability and engagement, there is little consistency in the study protocol and metrics, making it difficult to compare outcomes across papers. We propose app researchers adopt standardized metrics to assess ease of use and engagement.

No. 206

Patient Attitudes Toward Telepsychiatry: Survey Data From 61 Veterans at the Captain James A. Lovell Federal Health Care Center

Poster Presenter: Krushen Pillay, D.O.

SUMMARY:

Background: Telepsychiatry serves as a modality that has not been commonly adopted as a primary intervention in either an outpatient setting or inpatient setting. Although this modality may improve access to mental health care in rural areas and may even decrease costs of care, significant barriers to care include possible harm to the therapeutic alliance, technical difficulties, as well as resistance by providers. Methods: In our study which took place at the Lovell Federal Health Care Center in North Chicago, IL, patients were recruited and underwent surveys about their attitudes towards telepsychiatry. 61 veterans were surveyed following their telehealth appointments. The written questionnaire consisted of 5 questions in a Likert scale format in addition to an area for open opinions. One provider conducted all of the telepsychiatry visits. We found that the majority of patients were highly satisfied with their encounter. Results: Overall 95% of respondents approved of their telepsychiatry appointment. 62% of the respondents strongly agreed (5 on the Likert scale) that their relationship with their clinician did not differ from an in-person encounter. 80% of respondents strongly agreed that technical issues did not impair their clinical encounter. 80% strongly agreed that their needs were completely met and they would prefer telehealth over traveling to the clinic for their appointments. In ongoing phase 2 of the study, data is being collected on the differences in perception in providers' attitudes towards telepsychiatry which will be presented. Conclusion: Telepsychiatry appears to be a modality that is appreciated by patients, but underutilized by providers. Further research may be warranted to further investigate differences between in person visits and telepsychiatry visits. It is our intent to assess attitudes of psychiatrists with a similar survey posed to the patients. It may also be beneficial for further research into a hybrid model of care, where patients can be seen in person for some visits and via telepsychiatry for other visits. The study was not supported by any research funding.

No. 207

Mobile Integrated Neuropsychological Device Serving Evidence-Based Therapies (Mindset)

Poster Presenter: Ravi Varkki Chacko
Co-Authors: Omar Karadaghy, Elizabeth Russell, Chase Latour, Ryan Lindsay, Claude Robert Cloninger, M.D., Dehra A. Glueck, M.D.

SUMMARY:

Background: Mobile devices provide a unique ability to deliver behavioral health care in the wild. Pairing mobile devices with wearables allows the integration of heart rate (HR) and heart rate variability (HRV) data. HRV along with behavioral markers can provide a proxy for affective state [1]. This combination allows for novel personalized mental health care paradigms using ubiquitous devices [2]. However, the development of mobile therapies is systematically different from the development of other medical treatments. Here we propose, develop and test the clinical effectiveness of a mobile integrated neurofeedback device that detects moments of elevated physiological stress, and delivers in-the-moment evidence-based therapeutic exercises. Methods: The MINDSET application was developed for Android and iOS to pair with the MIO Alpha 2 wearable heart rate monitor (Mio Global. Vancouver, Canada). Mobile therapies included exercises from mindfulness [3], cognitive-behavioral therapy [4] and positive psychology [5]. Subjects engaged in mobile therapies after being notified or in a self-directed manner. Engagement goals and email feedback encouraged participation. We

employed standard HRV estimation [1] and motion classification methods to estimate physiological state. Initial testing was conducted with volunteers who submitted surveys before and after a month using MINDSET. After online app release, we analyzed usage statistics from 5823 downloads of Mindset from the app store. Next, we piloted the feasibility of MINDSET in clinical populations. Six participants with Tinnitus and comorbid depression used MINDSET features for 6 weeks. These subjects were surveyed with two Tinnitus inventories and the PHQ-9 before and after using MINDSET. Finally, the results from a population of 30 veterans with PTSD will be reported in February. Results: We demonstrate the proposed use case for MINDSET through recorded heart rate data with time stamped app events. A stressful event is followed by A) a notification, B) a therapeutic exercise, C) a reduction in HR and D) an increase in HRV. After one month's use, the sub-clinical population showed a reduction in feelings of anxiety (STAI)[6] and depression (BDI) [7]. MINDSET users returned an overall satisfaction of 4/5 stars. App-only users had a 2-week retention of 21%, triple the average of the average (7%). App-and-wearable users had a 2-week retention of 43%. The tinnitus cohort showed reductions in the Global Bothersome Score [8] (pre: 3.66, post: 3.00) and the PHQ-9 [9] (pre: 11.16, post: 9.66). Conclusions: We conclude that MINDSET can detect autonomic events and deliver clinically relevant therapeutic exercises. Data from sub-clinical users suggested that wearable incorporation doubles engagement. Initial pilot studies suggest that the MINDSET app may improve depression in clinical populations.

No. 208

How Facebook Has Influenced the Disclosure of Psychological Suffering

Poster Presenter: Ross E. Goldberg, M.D.
Co-Authors: Leah Susser, M.D., Julie B. Penzner, M.D.

SUMMARY:

The social media website Facebook has provided a new public and private venue for psychological expression. Airing of psychological grievances on Facebook has implications for the recognition of symptoms of mental illness, and for access to care for the affected individuals. In this case series, we present four patients, whose Facebook use led others to be concerned about their mental health, leading to inpatient hospitalization for each patient. Ms. A is a 49 year old female with a history of major depressive disorder and generalized anxiety disorder, who presented to the hospital when a friend notified police about a private Facebook message sent by Ms. A that stated, "I think I am going to go soon. I love you guys," with a photo of Ms. A with a noose around her neck. Ms. S is a 22 year old female without a formal psychiatric history who presented for her first hospitalization after her parents were alarmed by a series of public Facebook posts disclosing a history of sexual abuse. Mr. E is a 24 year old male with a history of bipolar disorder and multiple psychiatric hospitalizations, who was brought to the hospital when inappropriate Facebook posts revealed his manic behavior. Mr. M is a 27 year old male with a history of schizoaffective disorder, whose decompensation was identified after he posted on Facebook about his paranoid delusions about the Jewish people. Although any of these patients might have come to clinical attention even in the absence of Facebook, in all cases, the use of Facebook resulted in efficient provision of emergent mental health treatment. However, it is not known how often individuals post distressing content on Facebook that never comes to clinical attention. The potential utility of social media as a gateway to recognition of psychiatric decompensation should be characterized and investigated. Potential clinical and treatment implications include early recognition of problems, access to care, and interruption of suicide attempts. Software dedicated to recognition of irregular or alarming language or images might be helpful and is already in development. There are psychodynamic implications to use of a public forum such as Facebook for discussion of mental health symptoms, and exploration of such symptoms might create interesting fodder for psychiatric treatment. The unregulated, large, and open environment of Facebook was unavailable to previous generations, but is now ubiquitous. Facebook has proven important in cultural and social change, and problematic Facebook overuse is already being studied. It is both intriguing and culturally important to explore underlying demographics, diagnoses and characteristics of those who use Facebook in a manner that exposes their mental health problems.

As the presence of technology and social media continue to grow, an understanding of the interactions of these media with psychiatric presentation will be important to the recognition of symptoms and provision of care.

Sometimes They Are Watching You: Using Social Media to Monitor Compliance With a Court-Ordered Treatment Plan When Substance Use Impairs Progress

Poster Presenter: Brandy Orr Kalami, D.O.
Co-Author: Kimberlee V. Wilson, D.O.

SUMMARY:

Mr. X is a 36-year-old Caucasian male with a history of poly-substance abuse of alcohol, cannabis, and intravenous methamphetamine. He presented for the first time to a psychiatric facility on an involuntary evaluation order. Written testimony by his father alleged the patient displayed bizarre behavior, would instigate fights with his sister and talk to himself late at night. The patient admitted to auditory hallucinations and had a fixed belief that the United States government was monitoring him through a computer-brain interface chip, which he believed was placed in his head during a dental procedure. The patient acted on these paranoid delusions by calling the United States Army, the Central Intelligence Agency, and various other entities and university departments in order to communicate with scientists about this inserted technology. After communication with a United States Army recruiting station, an agent with the Federal Bureau of Investigation visited the patient at home, and recommended to his father that the patient receive inpatient care at a psychiatric facility. Once evaluated and treated, he was stabilized on a second-generation antipsychotic long-acting injectable and discharged with a physician's recommendation of court-ordered participation in follow-up outpatient psychiatric care. An avid user of social media, Mr. X documented on video his daily activities for months leading to his hospitalization. Video included illicit drug use and verbal response to delusions. He created a social media page for people who believed themselves to be targeted and surveilled by the United States federal government. Months after discharge from the inpatient facility, he has continued to share his drug use and delusional activities, even documenting his monthly scheduled injections that were recommended by physicians and required by the mental health court. Using this case as an example, we will explore the considerations for recommending court-ordered outpatient psychiatric care, the physician's responsibilities to the patient and the public, and the advantages and disadvantages of legally required psychiatric treatment.

Resident Development of Learning Modules for Teaching Ethics in Psychiatry With a Sample Case: Voluntary Stopping of Eating and Drinking

Poster Presenter: Chelsea Wolf, M.D.
Co-Authors: Melanie K. Miller, M.D., Jacqueline Norman, D.O., Donna T. Chen, M.D.

SUMMARY:

Background: Medical ethics is an important component of both undergraduate and graduate medical education. Particularly in psychiatry, there is frequently a need for cases to be addressed not only from a psychiatric perspective, but from an ethical one as well; the decision-making capacity of patients with severe mental illness may be less clear, patients may be hospitalized against their will, and societal resources to support those with mental illness are frequently sparse. As such, ethical decision-making skills are of great importance. At the University of Virginia (UVA) School of Medicine, medical students on their psychiatry rotations, as well psychiatry residents, expressed a desire for a more robust medical ethics curriculum, specifically as it pertains to psychiatric patients and cases. Objective: Given this, the co-presenters, fourth year psychiatry residents together with a faculty mentor, took a longitudinal developmental approach to creating a robust Ethics in Psychiatry thread through the curriculum for medical students and psychiatry residents at UVA following Kern's 6 steps of curriculum development for medical education(1): 1) problem identification and general needs assessment; 2) targeted needs assessment; 3) goals and objectives; 4) educational strategies; 5) implementation; and 6) evaluation. Description of proposed curricular design with case example: We chose in-person, case-based teaching modules with

a standardized format as an educational strategy. Multiple representative ethical cases were selected that could occur in either inpatient or outpatient settings and that could potentially result in different decisions. Reflection and discussion questions were framed around the specific ethical issues relevant to the case. Finally, an Instructor's Guide with a list of references for further reading was developed to enable other senior residents or faculty to lead a discussion regarding that particular ethical scenario. This poster will highlight the case of an elderly woman who refused nutrition and hydration as a means of suicide, and will address the important ethical topic of Voluntary Stopping of Eating and Drinking (VSED). Next Steps and Conclusion: Six 50-minute modules for teaching Ethics in Psychiatry will be presented monthly to medical students and residents. Ongoing evaluation and refinement of the modules as important components to a larger curriculum will be essential moving forward as we work towards improving the comfort with, and competence in, dealing with difficult ethical cases in the field of psychiatry.

No. 211

Physician Aid in Dying: A Health Care Worker Seeking Palliative Care as a Mechanism of Suicide

Poster Presenter: Daniel A. Neff, M.D.

SUMMARY:

This poster will present the clinical history of a fascinating patient who sought to use palliative care as a mechanism of suicide. Ms. W was an 82 yo woman with no significant past psychiatric history nor any significant medical problems. She had been retired from a fulfilling career as a surgical nurse and had an active social life with peers and younger women. She was widowed roughly ten years prior to presentation without significant impairment and had no children having married at 53 yo. The patient presented to my care after being discovered by a friend to be engaged in an ongoing attempt at starvation as a way to qualify for hospice care. She adamantly denied depression, or any disturbance of mood. She reasoned that she had started to notice some problems with mobility, and this caused her to conclude that she had arrived at a point where she could only be more of a burden to society than a benefit. As such, she adamantly maintained that the only ethical decision available to her was to commit suicide. She reasoned that starving herself to "the point of no return" would allow her to qualify for hospice and dignified death. After extensive bedside intervention by myself, the patient was agreeable to hospitalization on an academic Geriatric Psychiatry unit. She continued to insist she had no psychiatric problems and couldn't be dissuaded from her plans. The morning after transfer she was found in her room aphasic and not moving her right side. Rapid response protocol was initiated and she received therapeutic t-PA. Despite aggressive intervention she was found to have a completed infarction of the full territory of the middle cerebral artery and never recovered consciousness. Consistent with her wishes she was placed on hospice protocol and died a week later. Ms. W's stroke occurred on the morning of her birthday. After discussing the case, a presentation of ethical guidelines from the literature on physician aid in dying will be reviewed. Additional points from the literature will include key points of debate on the topic of "rational suicide" - if such a thing can exist. Furthermore, the poster will suggest the possibility that the stroke was not an accident but a completed suicide and explore questions of therapeutic futility in coerced care.

No. 212

Psychiatric Ethics Case Discussion Modules Developed by Residents: Covert Medication Administration/Medications Over Objection Case

Poster Presenter: Jacqueline Norman, D.O.
Co-Authors: Melanie K. Miller, M.D., Chelsea Wolf, M.D., Donna T. Chen, M.D.

SUMMARY:

Medical ethics as it pertains to psychiatry often deals with controversial cases that do not have one clear protocol to follow because these cases are not identical and can involve a vulnerable population of patients that may not have decision making capacity. For this reason, psychiatric ethics case discussion modules were developed by the University of Virginia (UVA) psychiatry residents with a faculty mentor to address ethical considerations that can be used in practical situations in both outpatient and inpatient settings. These modules are intended to allow the user to gain practical skills to address various ethical situations in psychiatric patients and

more specifically for enriching the curriculum for medical students as well as psychiatry residents at UVA. Each module includes a brief case scenario, reflection/discussion questions, further readings that relate to the case discussion and an instructor's guide to successfully facilitate a group discussion. This module will discuss the controversy of covert medication administration/medications over objection as an ethical dilemma that commonly arises when treating psychiatric patients. These case modules are intended to improve familiarity and competence in managing ethical cases in psychiatry.

No. 213

Ethical Dilemmas at the Intersection of Mental Illness and the Criminal Justice System: A Case Study

Poster Presenter: Jessica Marie Khan, M.D.

SUMMARY:

A 53-year-old African-American male with a long history of schizophrenia was hospitalized for a psychotic exacerbation and assigned to the care of a first-year resident. He displayed extreme disorganization, paranoia, and distrust of medication. His history was significant for three separate criminal incarcerations totaling over 25 years of imprisonment for seemingly minor thefts. Prior to sentencing, he went to the state psychiatric hospitals for restoration of competence. While in prison, he was frequently placed in solitary confinement because of disorganization, medication-nonadherence, and psychotic agitation. Preceding the onset of illness, he exhibited above-average academic performance and good social adjustment. He was married with 2 children and served as a Marine for 9 months before honorable discharge. His psychotic symptoms progressed in association with cannabis and cocaine use. Brief periods between incarcerations were marked by episodes of stabilization while he took antipsychotic medications. However, when he self-discontinued medications, he became floridly psychotic and committed minor crimes. He received little guidance on how to survive outside of prison and his schizophrenia was inadequately treated. When he arrived at our hospital, he was quite psychotic and suffered from anosognosia, making him very difficult to treat. Struggling to help this patient brought forth several ethical dilemmas. Wary of medical treatment and operating under the principle of autonomy, he refused medications many times. However, as demonstrated by his history, he was unable to maintain a safe environment for himself when psychotic and committed minor crimes that led to imprisonment. Knowing the high risks of nonadherence with subsequent psychotic exacerbation and possible imprisonment instilled a sense of duty and urgency in the clinician to treat the patient to prevent this bad outcome. The delicate balance between autonomy and beneficence is often challenging to negotiate and particularly difficult to learn as a resident. This patient also suffered from social injustice as he experienced reduced access to mental health care while incarcerated; had he had better treatment for psychosis, he may not have committed crimes. He lacked opportunities for employment and housing, as often happens to people stigmatized by a prison record and mental illness. In addition, his long-term imprisonment was expensive, harmful to his health, and provided little benefit to society as the patient was unable to be gainfully employed or support his family or community because of his severe symptoms. If he had received proper care early in his illness while he was in prison, his disease may not be as devastating and he may have been a productive member of society. Opportunities for intervention in this case will be outlined using the sequential intercept model and ethical challenges will be considered in the context of the physician's role and responsibility.

No. 214

Autism Spectrum Identification Rates in African American Children Remain Low Despite Otherwise High Mental Health Diagnosis Rate

Poster Presenter: Joseph Christman Hart, M.D.

SUMMARY:

Purpose: This cross-sectional analysis describes the prevalence of individual psychiatric disorders in African American and Caucasian children in West Virginia. Methods Medicaid claims data were collected between XX and XX, and analyzed for both African American and Caucasian children between ages 2-17. Only children who had a clinical encounter with a psychiatrist or psychologist were

included in the study. Chi square test was used to test for significance between racial groups. Results Data for 16,548 children was included in the study. There was an insufficient number of enrollees of other races to allow useful analyses: Asian, Hispanic, and Native American races collectively accounted for less than two percent of the population, so these were not included in the study. African American children were nearly five times as likely to receive a diagnosis of child abuse compared to Caucasian children (5.4% vs 1.1%). Rates of PTSD were similar (5.4% African American vs 1.5% Caucasian). African American children were also nearly twice as likely to receive a diagnosis of Adjustment Disorder or Major Depressive Disorder compared to (15.8% vs 8.5%). Interestingly, Caucasian children were considerably more likely to receive a diagnosis of Autism Spectrum Disorder (24.0% Caucasian vs 16.5% African American). Conclusion: Despite high rates of mental illness diagnosis rates in African American children, Autism Spectrum disorder remains identified considerably more frequently in Caucasian children.

No. 215

Seeking Expertise in Addressing Ethical Dilemmas in a Case of Anorexia Nervosa

Poster Presenter: Kruthika Sampathgiri, M.D.

SUMMARY:

Introduction The lifetime prevalence of anorexia nervosa in the United States adult general population is about 0.6 percent [1]. Psychiatry is often consulted to assess the decision making capacity of patients with delirium, psychosis or major neurocognitive disorders. In patients with eating disorders who have a high risk for medical complications this can often be a complex decision. They often meet the standard for being able to verbalize and explain their decision making process logically, while there is concern that they are making poor choices influenced by their prevailing or co-existing mental illness. Striking a balance between respecting patient autonomy and the desire to act in a beneficent manner is one of the ethical dilemmas we continue to face often [2]. Case Presentation We present the case of a 31 year old female, with past psychiatric history of Anorexia Nervosa, paraplegia secondary to a diving accident; admitted to the medical service for sinus bradycardia, requiring a permanent pacemaker and subsequent removal secondary to it being complicated by a small pneumothorax. Her inpatient course was also complicated by a stage IV sacral decubitus ulcer, requiring a surgery consultation. Psychiatry was consulted for patient's refusal of oral and PEG tube feeds and to assess her capacity for refusal of treatment. Initially, it was determined that she had the capacity based on her ability to understand the information presented to her, appreciate the diagnosis, medical risks and concerns involved and, infer the consequences of her choices [3]. We were faced with multiple dilemmas during her care, which included, were her decisions and poor choices due to her depression, and hence did she actually have the capacity to make decisions in this current mental state? If in fact she did lack capacity, and the next of kin was identified to help with decisions, would this necessarily change her outcome? In spite of expert opinions and recommendations from multiple teams which included Psychiatry, Surgery and Cardiology, she continued to refuse care, and her health deteriorated drastically. Palliative care was then consulted, and eventually a DNR was made in conjunction with her mother's agreement. The patient subsequently passed away two weeks following her admission. Discussion As medical professionals, we are inclined to prevent death and pressured to fix all problems, leading to aggressive treatment strategies. Having unrealistic expectations and goals, one can easily overlook the importance of providing emotional support and alleviate suffering. Some of the most common ethical dilemmas to steer through arise when the patient's desires conflicts with the physician's duty to look out for the patient's best interests. Knowing when to consult the right experts and to identify the best appropriate time to do this, keeping in mind patient satisfaction is of extreme importance in such scenarios.

No. 216

A Multidisciplinary Collaborative Approach to Address Substance Use and Mental Illness During Pregnancy to Promote Better Outcomes for the Infants

Poster Presenter: Howard Joseph Osofsky, M.D., Ph.D.

Co-Authors: Larry Burd, Natalia L. Rasgon, M.D.,

Ph.D., Erich J. Conrad, M.D., Joy Osofsky, Ph.D., Joshua Sparrow, M.D., Michele Many, Tonya Hansel, Ph.D., L.M.S.W.

SUMMARY:
Substance abuse during pregnancy and negative outcomes for newborns affects not only the individual but also society at large with the significant increases in frequency and severity. Concurrent with substance use is under-recognized serious mental illness which is often not identified or treated at this vulnerable time for both mother and newborn. Recent research demonstrates a large increase in newborns born dependent on opiods (Neonatal Abstinence Syndrome) as well as those diagnosed with Fetal Alcohol Syndrome resulting in increased costs associated with treating them at 1.5 billion dollars annually. In addition to services required to provide treatment for addicted mothers, long term services are often needed to meet the developmental needs of high risk infants. While, as many as 20% of pregnant women may experience new onset and recurrent major mood, anxiety, and even psychotic disorders during pregnancy, serious mental illness is often not addressed adequately during pregnancy and the postpartum period. Both substance use during pregnancy and mental health concerns can contribute to premature birth, biological risk, increased cesarean delivery, and post-partum depression. With increased risk for the mother and newborn, the infants may have medical and behavioral problems that can lead to more negative outcomes. The medical and mental health problems can also adversely affect parent-infant attachment and infant development. The Departments of Psychiatry, Obstetrics and Gynecology, and Pediatrics at Louisiana State University Health Sciences Center have developed a collaborative program to address this problem integrating medical and mental health services to increase the quality of care. The Department of Psychiatry provides evidence-based mental health and substance abuse consultation and services for pregnant women with plans to continue services during the perinatal and postnatal periods. Maternal and Infant Health (MIH) Specialists—social workers with expertise in trauma, serious mental illness, and substance abuse—collaborate with physicians and staff in working with high risk pregnant women when they present at the University Medical Center, Maternal Fetal Medicine Clinic and from other Obstetrical Clinics. Client participatory input is essential in program development. The MIH specialists meet with the mothers during prenatal appointments and using telepsychiatry to provide a supportive relationship during pregnancy and after the baby is born. Mental health professionals also provide education for physicians, residents, and hospital staff on mental health, infant mental health, motivational interviewing and evidence-informed parent-infant interventions such as the mother-infant Touchpoints intervention. His innovative and collaborative multidisciplinary program will benefit both mothers and infants and reduce short and long-term costs by increasing access to mental health support as part of overall health services.

No. 217

A Consult-Liaison Challenge: Serious Persistent Mental Illness, Terminal Disease, and Fighting Physicians

Poster Presenter: Samantha Zwiebel, M.D., M.A.

SUMMARY:
Introduction: This consult service case involved all four domains of bioethical principles—autonomy, non-maleficence, beneficence, and justice—with all domains in conflict, resulting in significant physician discord. There is little guidance for psychiatrists providing both consult and liaison services in cases where the patient's chronic mental health issues complicate care at the end of life when treatment is contentious. Case Description: The patient was a 53-year-old woman with schizoaffective disorder and persistently delusional and paranoid at baseline, well known to the state psychiatric hospital. After presenting there for psychosis, she was transferred to the academic hospital for pneumonia, but management of her previously diagnosed small cell lung cancer became a priority upon arrival. Her specific cancer was susceptible to chemotherapy but she never had outpatient care. Psychiatry was consulted because the patient was too psychotic to participate in treatment. Restarting the patient's psychotropic medications resulted in sedation, which led her husband to defer chemotherapy. Ethical Issues: During this time, discussion with the patient's providers at the state psychiatric hospital

revealed that she was rather headstrong and consistently refused most treatments. In their opinion she would not want or be able to participate in chemotherapy even in her best of mental health. One provider expressed distinct disgust at the plan for chemotherapy as a violation of what autonomy the patient could preserve, despite a clear lack of capacity. A meeting with Bioethics led to the attending oncologist blaming Psychiatry for poor control of symptoms that resulted in the patient's inability to have chemotherapy, causing a delay in potentially life-prolonging treatment solely because of mental illness. The oncologist interpreted acceptance of the patient's psychotic baseline as Psychiatry's incompetence and indifference, which in turn prevented the oncologist from delivering care. However, the resident physician on the Oncology team disagreed with offering chemotherapy from a medical perspective, and Internal Medicine asserted chemotherapy would be unethical insofar as it would prolong and promote suffering. Results: Ultimately, the attending oncologist rotated off service, the new oncologist was against chemotherapy, and the patient's husband decided in favor of palliative treatment. The patient expired within 2 weeks from status epilepticus due to brain metastases. Conclusion: In the aftermath of this case, the academic hospital held several meetings to address the issue of physician conflict, as this case was never truly resolved and remains ethically unsettling. This case also challenges the scope of consult-liaison psychiatry and the potential role of the psychiatrist in advocating for SPMI patients.

No. 218

The Role of Psychiatric Consultation in Cases of Rapidly Progressive Dementia: A Case and Literature Review

Poster Presenter: Daniel Shalev, M.D.
Co-Author: Nuri Jacoby

SUMMARY:

Background: Rapidly progressive dementias (RPDs) are a diverse group of illnesses with a progression to significant impairment in weeks to months. Although there are overlaps, the differential diagnosis of RPD differs markedly from that of the other dementias. Because RPDs may be mistaken for primary psychiatric disorders, and entail significant psychiatric symptom burden as they progress, psychiatrists are often involved in the diagnosis and management of these disorders. The aim of this presentation is to discuss a diagnostic dilemma in a case of RPD and to provide a narrative review of the literature on RPDs. Methods: A case report and a narrative review of the literature through targeted keyword searches of the MEDLINE database. Selected articles underwent two person review for relevance. Case: We describe a case of a 70 year-old woman without past psychiatric or neurologic history who initially presented to the psychiatric emergency department with one month of confusion, inability to perform ADLs, and psychotic symptoms, who was admitted to the neurology service with psychiatry consulting. The patient underwent extensive neuropsychiatric workup including imaging, EEG, CSF, and serum studies, which were significant primarily for mildly elevated inflammatory markers and a positive anti-thyroid peroxidase antibody titer. She was given a presumptive diagnosis of Hashimoto's encephalopathy and treated with steroids and with intravenous immunoglobulins, as well as lose dose antipsychotics for psychotic symptoms. She experienced only minimal improvement on this regimen and was ultimately discharged to a skilled nursing facility and workup was continued on an outpatient basis. Results and Discussion: Our search yielded 381 results, of which 34 were selected for review and 21 were included after screening for relevance and excluding articles pertaining only to prionopathies. Based on the literature and our case discussion, we elucidate the role of the psychiatric consultant in cases of RPD including: (1) diagnostic clarification (including a review of the differential diagnosis of RPDs) (2) management of behavioral and psychiatric symptoms (3) facilitating communication and education of the patients' families, and (4) liaison with the primary team around issues of therapeutic fatigue and hopelessness arising from diagnostic challenges and limited available therapeutic interventions. Conclusion: RPDs are a varied group of diagnostically and therapeutically challenging neuropsychiatric disorders. We utilize a case report and literature review to operationalize the important role of expert psychiatric consultation in the workup and management of patients presenting with RPD.

No. 219

Neurology Training for Psychiatry Residents: A Narrative Review

Poster Presenter: Daniel Shalev, M.D.
Co-Author: Nuri Jacoby

SUMMARY:

Objective: To formulate an operationalized approach to neurologic training of psychiatric residents based on review of existing guidelines and data. Background: Both the Accreditation Council for Graduate Medical Education (ACGME) Psychiatry Milestone Project and the American Board of Psychiatry and Neurology (ABPN) Core Competency Outline stipulate that psychiatry trainees should develop proficiency in the neurologic exam and an understanding of the intersection between psychiatric and neurologic disease. Although psychiatry residents are mandated to complete two months of full time clinical neurology, there is no standardized system for evaluating and sustaining clinical neurologic skills. Design/Methods: We conducted a narrative review of the literature on neurology education in psychiatry residency training from 1990 to 2016 using the EMBASE and MEDLINE databases. Included citations underwent two-person review for relevance and citation review. We additionally reviewed ACGME, ABPN, and American Neuropsychiatric Association (ANPA) guidelines pertinent to the neurologic training of psychiatric residents. Results: Our search yielded 291 unique EMBASE results and 605 unique MEDLINE results. Of these, 39 were for review and 26 were ultimately included. Based on data and existing ABPN, ACGME, and ANPA guidelines, the following neurology training goals were identified: (1) board-readiness, (2) ability to detect and triage neurologic conditions common to the psychiatric setting, and (3) use of clinical neurologic skills for the diagnosis and management of neuropsychiatric disorders. Barriers identified were: (1) poor standardization of clinical neurologic training among psychiatry residency programs, (2) progressively decreasing comfort with neurology as residents move into full-time psychiatric settings, perhaps contributed to by (3) generally low rates of neurologic and physical examination of patients in the primary psychiatric setting. Discussion: Based on our findings, we suggest a targeted approach to neurologic training of psychiatric residents including increased standardization of clinical neurologic experiences with emphasis on examination skills and neuroradiology, longitudinal neuropsychiatric supervision, and interdisciplinary training and didactic experiences on psychiatrically germane neurology topics.

Decreased Interoceptive Awareness Is Associated With Impaired Decision Making in Patients With Substance Use Disorders

Poster Presenter: Mehmet Bulent Sonmez
Co-Authors: Busra Subay, Rugul Kose Cinar, Yasemin Gorgulu, Mehmet Erdal Vardar

SUMMARY:

Background: The current study was prepared based on the assumption that awareness of the interoceptive processes may be disturbed in addicted individuals. The individuals with poor interoceptive awareness (IA), who are not able to utilize sufficiently body-relevant signals and rely on non-emotional sources to guide their decision-making, may choose more disadvantageous and fewer advantageous options in a complex and uncertain decision situation. Methods: The participants in the study included 80 abstinent male inpatients who were addicted to alcohol (n=40) or heroin (n=40) according to the DSM-5 criteria for substance use disorder (current severity: moderate or severe) and 40 healthy male volunteers. All participants performed the heartbeat perception (HBP) task as an objective physiological performance measure of IA and a computerized version of the Iowa Gambling Task (IGT) as a validated measure of decision-making. Results: Patients addicted to alcohol or heroin had similar IA, and their HBP scores were significantly lower than those of healthy control subjects ($p<0.05$). Patients addicted to alcohol or heroin had similar decision making performance and they performed significantly worse on the IGT compared to healthy controls ($p<0.05$). There was a significant positive correlation between

HBP scores and total net scores on IGT ($p<0.05$). Conclusion: As our main finding, a decrease in IA in addicted patients in comparison to healthy controls may provide support for the hypothesis that awareness of the interoceptive processes may be disturbed in addiction, and poor perception of somatic feedback in addicted individuals relates to decision-making processes in terms of selecting more disadvantageous and fewer advantageous options in complex and uncertain situations.

No. 2

Study on Psychosocial Factors and Cigarette Smoking in Schizophrenia

Poster Presenter: Mei Wai Lam, M.D., M.P.H.
Co-Authors: Alessandra Dumenigo, Bishoy Goubran, M.D., Marcos Sanchez-Gonzalez, M.D., Ph.D.

SUMMARY:

Background: The high prevalence of cigarette smoking in patients with schizophrenia (SCZ) has been traditionally attributed to the self-medication hypothesis which suggests that cigarette smoking helps patients cope with their symptoms and medication side effects. However, the association between smoking and psychosocial factors that may contribute to the high prevalence of smoking in schizophrenia is less understood. The aim of this study was to understand the social factors associated with cigarette smoking behaviors in patients with SCZ. We tested the hypothesis that psychosocial factors including social network and health literacy level influence smoking behaviors among patients with SCZ. Methods: Cross-sectional observational study was conducted involving 114 subjects with SCZ. Subjects were recruited from inpatient, partial hospitalization program and outpatient clinic. Questionnaires and scales including Short Assessment of Health Literacy (SAHL), Cohen's Social Network Index (SNI), Fagerstrom Test for Nicotine Dependence (FTND) and PANNS-6 (Short version of Positive and Negative Symptoms in Schizophrenia) were used. Results: There were 63.16% smokers in our sample (N=114), which was consistent with the high prevalence of smoking in SCZ in previous studies. The odds of being a smoker decreases by 79% in participants at clinic setting compared to participants at inpatient setting ($p=0.004$). In addition, concurrent drug use and alcohol use were significantly associated with cigarette smoking in the patients with schizophrenia. The odds of smoking was 3.4 times higher in patients using alcohol ($p=0.016$) and the odds of smoking was 3.9 times higher in patients using drugs ($p=0.0102$). Among the smokers, BMI ($p=.026$) and pack years ($p<0.0001$) were positively and significantly associated with FTND score. It was found that social network and health literacy did not play a role in predicting smoking. There was no significant difference in PANNS-6 scores among smokers and nonsmokers. Conclusion: Due to the high prevalence of smoking in patients with SCZ reported in other Western countries, the study results could likely be generalized to other mental health settings. Since the odds of being a smoker was found to be significantly less in outpatient clinic compared to inpatient setting, the result suggests that there was an association between severity of SCZ and smoking status. The significant association between cigarette smoking, alcohol use and drug use suggest that the factors associated with substance abuse must be taken into consideration together in this patient population. Further interventions intended to address concurrent nicotine, alcohol and drug use among patients with SCZ are warranted.

Kratom-Induced Agitation of a Chronic User of Kratom

Poster Presenter: Michael R. Harrigan, M.D.
Co-Authors: Nirali Dave, Asghar Hossain, M.D., Avi Siwatch

SUMMARY:

Kratom (Mitragyna speciosa) is a plant that has long been used in Southeast Asia, dating as far back as the 1800s. It has been used for medicinal purposes such as: cough, diarrhea and intestinal infections. However, it is also known to have psychotropic effects such as euphoria, relaxation and anxiolytic properties , as well as pain relief similar to opiate medication. Based on this, kratom has been used as both as an opioid substitute and an aid for opiate withdrawal. Kratom can be consumed orally or smoked and is now widely available on the Internet

and on the streets with varying levels of legal status. Its popularity among the drug-using population continues to rise owing to new substance use related issues. Here, we present the case of a 20-year-old-male who has been consuming a large amount of kratom for an extended period of time who was admitted to a MICA inpatient unit with worsening anxiety and depression as well as increased agitation in the context of kratom intoxication/ withdrawal. He was managed with psychotropic medications for several days for withdrawal symptoms.

No. 5

How Effective Is D2 Partial Agonists at Eliminating the Cravings of Cannabis in a Psychotic Patient?

Poster Presenter: Myriane Isidore, M.D.

SUMMARY:

There is currently no medication that is approved by the Food and Drug Administration to help prevent relapse from cannabis misuse in a patient that has a comorbid diagnosis of either Schizophrenia or Schizoaffective Disorder. Patient's with dual diagnoses are highly prone to adverse outcomes in several domains such as increased symptom severity, increased rates of hospitalization, violence, victimization, homelessness and non-adherence to medication as well as poor overall response to pharmacologic treatment. The aim of this study is to determine if Abilify oral or long acting injection formulations will decrease the time it takes to relapse on cannabis during a one year interim. The standard treatment group will receive a typical antipsychotic, Haldol PO or Haldol Dec Injections and the time of relapse will be compared amongst the nonstandard Abilify treatment group. After patients have met the inclusion criteria, they will sign an informed consent in order to be included in the study. We will assess patient's relapse after patients voice recent drug use during therapy sessions or by evidence of a positive urine toxicology screen obtained from monthly outpatient visits. No personal information will be used and information will be entered in a password-protected Excel spreadsheet, accessed by the principal investigator and coordinators only. The data will be statistically analyzed to identify the differences in relapses amongst the standard and nonstandard treatment groups. Data will be available once study commences. This study will help the scientific community to better understand how effective D2 partial agonists will be at decreasing drug seeking behavior, reducing the intensity of cravings thereby increasing patient's compliance to treatment.

No. 6

A Slippery Slope: Abrupt Discontinuation of Phenibut Resulting in Mania With Psychotic Features

Poster Presenter: Nuzhat Hussain, M.D.
Co-Authors: Asfand Khan, M.D., Sanjay Yadav, M.D., Andrew Davis

SUMMARY:

We present a case of a 26 years old male with no significant past psychiatric history, who was admitted to our inpatient psychiatric facility for first episode of mania with psychotic features. The patient and his family reported that he was using Phenibut, a supplement he had purchased online and was using in escalating doses for the past 2 months. Once he realized the addictive potential of Phenibut, he stopped the supplement abruptly. Two days following discontinuation, he was observed to be acting in a "bizarre manner" and was later arrested after an altercation with the police. Patient's mental state continued to worsen during his 1 month stay in prison. He was admitted to the medical floor for suspicion of delirium. Basic laboratory tests and studies including EEG, CT scan and MRI brain were unrevealing. Lumbar puncture, Lyme titer and HIV screen were also negative. At the inpatient psychiatric facility, the patient endorsed delusions, stating he was "the son of God" and all people around him were "deities". He was notably disinhibited and required less amount of sleep. Thought process was prominent for loose associations and thought blocking; he also endorsed auditory hallucinations and appeared to be internally preoccupied. Over a period of 2 months, he failed trials of Risperidone, Lithium, Olanzapine and Valproic acid. Clozapine was initiated and titrated to a dose of 600 mg, which resulted in marginal improvement. ECT was commenced and the patient's symptoms showed marked improvement after 4 sessions. He was later discharged on maintenance ECT and 400 mg daily dose of

Clozapine. Discussion: Phenibut, primarily a GABA-B analog and to a lesser extent GABA- A, is known to have anxiolytic and cognition enhancing properties. It is approved for use in several countries for multiple indications including anxiety disorders, alcohol withdrawal and insomnia.2 Phenibut is not FDA approved in US, but is widely available via the internet. Phenibut's euphoric properties along with quick development of tolerance make it a potentially addictive substance. Moreover, abrupt discontinuation can result in withdrawal symptoms ranging from rebound anxiety, insomnia, restlessness, delirium, agitation and frank hallucinations. 1 These symptoms are similar to withdrawal from GABA-ergic agents such as benzodiazepines and Baclofen. In our case, Phenibut withdrawal, appears to have precipitated a manic episode with psychotic features. Due to easy accessibility, use of Phenibut has greatly increased over time. Lack of regulatory status and limited research on the clinical effects of Phenibut pose a significant public safety risk and ongoing challenges for physicians in identification and management of Phenibut related intoxication and withdrawal syndromes.

No. 7

Cognitive Impairment Due to Synthetic Cannabinoids (K2) Use and Psychosis

Poster Presenter: Omotola O. T'Sarumi, M.D.
Co-Author: Uchechukwu Nnamdi, M.D.

SUMMARY:

Synthetic cannabis (synthetic marijuana), or technically synthetic cannabinoid receptor agonists are designer drugs that mimic the effects of cannabis sprayed onto a herbal base material. It was first sold under the name "Spice," the drug has evolved into many different names (e.g., Black Diamond, Mojo, Spice Gold, Aroma, Dream, Genie, and Silver). K2 or "Spice" is made of a C8 homolog of the non-classical cannabinoid CP-47, 497, 497-C8 (cannabicyclohexanol) and a cannabimimetic aminoalkylindole called JWH-018 In humans, psychoactive cannabinoids produce euphoria, enhancement of sensory perception, tachycardia, antinociception, difficulties in concentration and impairment of memory. The cognitive deficiencies seem to persist after withdrawal. The toxicity of marijuana has been underestimated for a long time, since recent findings reveal -THC-induced cell death with shrinkage of neurons and DNA fragmentation in the hippocampus. The acute effects of cannabinoids as well as the development of tolerance are mediated by G protein-coupled cannabinoid receptors. The CB1 receptor and its splice variant CB1A, are found predominantly in the brain with highest densities in the hippocampus, cerebellum and striatum. This case reports a 26 year old man with no prior psychiatric diagnosis who developed cognitive impairment and psychosis after the use of synthetic cannabinoids. In this case report, we also discuss the updated evidence base on the effect of delta-9- tetrahydrocannabinol (THC) on the brain.
Keywords Marijuana, THC, Psychomotor Memory, Synthetic Cannabinoids, Cognitive Impairment

A Preliminary Study for the Affective Style of Adults With Internet Gaming Disorder

Poster Presenter: Pei-Yun Lin
Co-Author: Chih-Hung Ko

SUMMARY:

Background: Loss of control in internet gaming could result in a negative consequences. The dyscontrol internet gaming had been defined as internet gaming disorder (IGD) in DSM-5. The study aimed to evaluate the affective regulation style of adults with IGD and the association between affective style and depression and anxiety of IGD. Methods: A total of 47 young adults with internet gaming disorder and 47 gender and age matched controls were recruited by advertisement. The classification was based on diagnostic interviewing based on DSM-5 research criteria and gaming behavior evaluation. They are arranged to complete the questionnaire for gaming behaviors, affective style questionnaire, Chen internet addiction scale (CIAS), the Penn state worried questionnaire(PSWQ) and the center of epidemiological studies depression scale (CESD). Results: There is no difference in gender (38 male and 8 female) and age (26.21±4.47 versus 26.68±4.34) between IGD group and controls. The t test demonstrated that IGD group had lower score in affective adjustment and higher score in CIAS, PSWQ, and CESD than controls. Further, the Pearson's correlation demonstrated that affective

adjustment negatively associated with the CESD and PSWQ score among IGD group. Further, the CESD and PSWQ score was positively associated with CIAS score. The logistic regression for IGD with control of gender, age, educational level, demonstrated that lower affective adjustment and higher affective concealing associated with IGD. However, these association became insignificant when the score of CESD enter the model. This result might suggest that depression mediated the association between affective adjustment and IGD. Conclusion: The presenting study suggested that lower affective adjustment and higher affective concealing could associated with the vulnerability of IGD. This would suggest that the emotional regulation ability should be well assessed and promoted among young adults with IGD. Besides, the affective adjustment was negatively associated with depression in IGD group. As depression could be one risk factor of IGD, intervention to promote affective adjustment, such as emotion reappraisal, might benefit subjects with IGD. Further, the depression could mediate the association between affective style and IGD. Thus, intervention to treat depression of IGD, such as antidepressants or exercise, might attenuate the association between affective style and IGD.

No. 9

Analyzing Substance Use Disorders/Patterns Among Oupatient HIV Patient Population Based on Various Demographic Factors

Poster Presenter: Rahul Patel, M.D., M.P.H.

SUMMARY:

INTRODUCTION: Human Immunodeficiency Virus (HIV) continues to be a major healthcare problem in the United States. As per CDC data; At the end of 2014, an estimated 1.1 million persons aged 13 and older were living with HIV infection in the United States. There are more than 1.2 million people living with HIV in the United States. Substance use, abuse, and dependence continue to be a major public health poblem and when studies into the HIV infected patient population. It is imperative to study gender based differences in substance use disorders within this sub-population in order to make and impliment health care policies. METHOD Our Sample population included HIV positive patients with substance use disorders and co-occuring mood disorders in a community outpatient clinic. Patients' substance use disorders were identified from the Drug Use Disorders Identification Test (DUDIT). Patients' sociodemographic variables were age (years), gender, race/ethnicity, education, employment, living status and have children. Clinical characteristics included years of diagnosis, CD4, viral load, Axis I Major depression and bipolar.The primary objective of this study was to analyze HIV positive patients with co-occuring mood disorders and alcohol use disorders in order to characterize gender differences associated with other social/demographic characteristics. Both univariable and multivariable logistic regression analysis were performed. RESULTS Based on the inclusion and exclusion criteria, 195 patients were identified with HIV+, Alcoholism and mood disorders. 61.5% patients are male and 38.5% are female. Overall, 43.1% patients used cocaine, 41.0% patients used cannabis and 14.9% used other substance (table 1).Male patients had higher total alcohol score than females (p=0.03), but we did not find significant difference in total drug score and age between male and female.Among 84 patients that used cocaine, 36 patients snorted cocaine (51% male and 31% female), 37 patients used crack cocaine (37% male and 54% female) and 11 patients used both (12% male and 15% female). Female patients had higher proportion in crack cocaine, but we did not find the significance in both univariable and multivariable models. CONCLUSION: This study was aimed to elucidate gender differences in an outpatient clinic HIV positive population with substance use disorders. Interestingly, we did not find a difference between female and male patient's drug use. We did find that of the people who snorted cocaine, only 31% were female while 51% were male. However, if we looked at the crack cocaine numbers, we saw a significantly higher proportion of women using crack at 54% compared to men at 37%.

No. 10

Self-Exclusion Program: "A Possible Tool"

Poster Presenter: Raul Quiroga

Lead Author: Raul Quiroga

Co-Authors: Andrea Espinardi, Lucía Bianconi

SUMMARY:

The Self-Exclusion is a tool that can implement the

Responsible Gaming Programs. It places inside the actions of Secondary Prevention, that is to say when "the game is a problem". It provides the possibility to the bettors, who like that need it, not being admitted to gaming rooms. We speak about tool because it only refers to the management of the symptoms of "abstinence" and possible relapses, that is, we understand self-exclusion as an auxiliary tool that contributes or helps in solving the problem or disease, in an supplementary way. This tool is only effective if the person concerned has taken "consciousness" for him her, throughout relatives or by therapeutic indication concerning about the situation experienced. From the Responsible Gaming Program of the Lottery of Córdoba State Society it was defined that the subscription to the self-exclusion program is voluntary. It lasts 4 years and its scope is Provincial. Its character is irrevocable with the exception of judicial order. The application is available on the web or in places of subscription, but it is only valid when completed in front of the staff designated for this purpose. This regime is confidential as for the preservation of the information of the applicant except under judicial requirement or of the solicitor. The process is personally and with companionship. The applicant must be presented with a national identity document (ID), two updates colored pictures, and photocopy of the ID. The accompaniment must show the ID too. The applicant commits to: Initiate specialized Treatment. Present every 6 (six) months certificate extended by a professional at the expense of this treatment and/or institution attend. In case the agreement is not completed, the term is extended automatically for 4 more years. On the part of the Lottery of Córdoba, it must guarantee the fulfillment of the agreement by arbitrating the means necessary for this purpose. In case of violating the agreement a sanction is contemplated. The violation is reflected in an Act of Infraction. The Act is valid even with the signature of the security personnel of safety. The penalty is accumulative. At the end of the requested period, an additional 4 years are applied for each violation report. The Program has signed 2092 self-exclusion applications since its beginning in November 2008; the distribution for sex of the applicants is 1425 men and 667 women. Of the historical total 892 people expired the stipulated period, 585 people requested the renovation and 615 are the new adherents. An articulated work is made between the Responsible Gaming Program - Personnel of Casinos and gaming rooms - Private Company Personnel (CET S.E.) for the implementation of the Self-Exclusion Program In conclusion, Self-Exclusion as a coadjuvant tool for psychotherapeutic treatment, taking into account the low adherence rates.

No. 11

Go Gaba Gaba! A Case Report of a 64-Year-Old Female With Chronic Opioid Withdrawal-Induced Back Pain, Anxiety, and Insomnia Managed With Gabapentin

Poster Presenter: Richard Stark
Co-Author: Consuelo C. Cagande, M.D.

SUMMARY:
Chronic opioid use and subsequent addiction is one of the largest problems facing American medicine today. The importance of devising how to best help chronic users discontinue their opioids and overcome the hurdle of withdrawal symptoms is a essential research area. The purpose of this case is to describe the use of gabapentin as an alternate treatment to manage the chronic withdrawal symptoms of a patient who took high-dose opioids for years. A 64-year-old female with a history of loin pain hematuria syndrome (LPHS) presented with 10 months of insomnia, back pain, and anxiety after discontinuing narcotic use. She was provided with behavioral counseling and pharmacologic intervention, which included gabapentin and a decreased dose of mirtazapine. The result was a dramatic increase in her sleep and a decrease in her pain and anxiety, allowing her to finally live an active and normal life after 25 years of chronic pain.

No. 12

Neuro-Education for the New Millennium: Innovating Medical Education Using Brain Based Teaching

Poster Presenter: Kevin H. Yang, D.O.
Co-Author: Vineeth John, M.D., M.B.A.

SUMMARY:
Ever since the Flexner Report, medical education has gone through manifold changes to take advantage of developments in the fields of adult education,

learning theories and varieties of learning delivery. In our technologically advanced age, the challenge continues to come up with a consistent set of learning principles around which to structure the bulk of undergraduate and graduate medical education. Given the vast volume of information expected to be learned and the summarily short time limit in which to learn it, many medical students and residents end up relying on third-party applications and non-traditional methods to succeed in the short-term. The challenges in information retention have ramifications even when the medical student transitions into residency and then as an independent professional stage. The effectiveness of lifetime learning programs such as annual CME are indeed limited. By analyzing the current educational research on neurological correlates for optimal learning, we seek to provide both an overview and real-world examples of various innovative medical education techniques. Most importantly, we would like to focus on improving each step of the learning cycle by: (1) enhancing information gathering abilities through sustained attention and providing emotional triggers for memory association (2) allowing for reflection with spaced repetition techniques built into the learning and training curriculum (3) engaging in creation through social stimuli to encourage manipulation of learned information (4) utilizing active testing through forced recall and question banks to ensure long-term retention of information. The presentation will reference studies showing the effectiveness of brain based teaching techniques and would also explore the potential for implementing such techniques into medical school curriculum and residency training programs.

No. 13

Long-Term Sequelae of Hallucinogen Use: Persisting Perception Disorder in the Context of LSD

Poster Presenter: Kevin H. Yang, D.O.

SUMMARY:

Mr. M is a 30 year old male who presented to the Emergency Department upon referral from a neurology clinic for an acute confusional state with hallucinations and perceptual disturbances. He had no notable psychiatric history or seizure history and was developmentally normal. His substance use included LSD use 2-3 years ago, use of psychedelic mushrooms 2 months ago, and continued marijuana use several times a month. Patient's last use of Cannabis was two weeks ago which was consistent with urine toxicology obtained on admission. Patient endorsed several unusual episodes over the past few years, including: (1) a feeling of traveling back in time to a previous city he had lived in (2) the environment around him changing to become more 'ominous and supernatural' (3) an interviewer's face morphing into his father's with the periphery phasing out (4) colors appearing throughout his vision (5) a bright spot throughout his vision with a bright zigzag following it (6) objects such as streetlights and buildings appearing to change dimension and 'lean over him' with a sense of impending doom (7) people appearing as though they were moving even while standing still. Long-term EEG monitoring did not show any epileptiform discharges or focal abnormalities even during reported 'typical' episodes. Given the lack of neurological or other medical explanation for these episodes and the consistency with which his symptoms match reported descriptions of Hallucinogen Persisting Perception Disorder (HPPD), we believe these findings are consistent with long-term sequelae of past LSD and psychedelic mushroom use, however remote. This case describes a classic clinical presentation of HPPD and highlight the importance of a thorough history-taking, medical, psychiatric, and neurological workup in diagnosing this disorder.

No. 14

Risperidone-Induced Amenorrhea in the Absence of Hyperprolactinemia

Poster Presenter: Muhammad Navaid Iqbal, M.D.
Co-Authors: Steven Vayalumkal, Mehwish Hina, Asghar Hossain, M.D.

SUMMARY:

Abstract One of the most well-known adverse effects of antipsychotic medications is hyperprolactinemia. Hyperprolactinemia can lead to a variety of symptoms as galactorrhea, oligomenorrhea, amenorrhea, and decreased libido. Due to its high affinity for D2 receptors, risperidone can block dopamine receptors in the Tubero-Infundibular pathway, resulting in elevated prolactin levels. Here,

we present the case of a patient who developed amenorrhea while on risperidone therapy with normal prolactin levels, whose menses resumed after discontinuation of risperidone. The patient is a 39-year-old female with no past psychiatric history of mental illness started exhibiting psychotic symptoms such as persecutory delusions, agitation, aggression, sexual preoccupation, and disorganized speech. The patient was hospitalized and risperidone 3mg BID was initiated. The patient's symptoms subsequently improved and she was discharged to home. A few months after risperidone was initiated, the patient noted that she had stopped menstruating. Prior to beginning antipsychotic therapy, menses occurred at regular intervals. The patient prolactin levels, thyroid function tests, FSH, LH, estrogen, progesterone, and DHEA levels, all of which were within normal limits. The decision was then made to discontinue risperidone and begin aripiprazole. Following this change in management, the patient's menses resumed as normal and she remained psychiatrically stable. Risperidone, as with other antipsychotic medications, is associated with a wide array of metabolic side effects including diminished libido, impotence, anovulation, irregular or absent menses, galactorrhea, and decreased estrogen and testosterone levels. Multiple case reports have shown increased prolactin levels in patients on risperidone therapy, and it has been shown that upon switching to another antipsychotic medication, including quetiapine, ziprasidone, and olanzapine, the hyperprolactinemia resolved. In the case of our patient above, amenorrhea occurred despite prolactin levels within the normal range. Other causes of amenorrhea, such as pregnancy, thyroid disease, and hormonal imbalance, were excluded in the patient. Upon switching her antipsychotic therapy to aripiprazole, the patient's menses resumed as normal without any disturbance in her psychiatric course. The use of antipsychotic agents, especially risperidone, carries with it the risk of adverse metabolic effects. Hyperprolactinemia due to these medications can cause a variety of metabolic symptoms, and both physicians and patients should be aware of these. In the majority of cases, these effects will manifest themselves in conjunction with elevated serum prolactin concentrations. The patient above presented with symptoms of amenorrhea in the absence of hyperprolactinemia that resolved once her medications were discontinued. Thus, it is important for physicians to remain aware of such cases in the future, as they may impact the choice of managemen

No. 15

Role of Quetiapine in Cannabis Use Disorder: A Systemic Review

Poster Presenter: Muhammad Navaid Iqbal, M.D.
Co-Authors: Mehwish Hina, Ghulam Sajjad Khan, M.B.B.S., Asghar Hossain, M.D.

SUMMARY:

Cannabis is one of the most prevalent abuse drugs across United States among adult population. The primary mode of action is its partial agonistic property on CB1 receptors in brain. The medical use of cannabis had been in much debate in previous years. It's use in this domain is variable and had been tried in chronic pain and spasticity with limited efficacy. The withdrawl effects of cannabis may include insomnia, irritability, restlessness, depression and mood swings. Long-term use may induce cognitive deficits and lapses in working memory. Very limited data is available on treatment modalities in managing cannabis use disorder. Quetiapine, an atypical antipsychotic has been used to diminish the frequency of cravings for cannabis use. In cases of significant cannabis use, patient may develop psychosis due to increase dopamine concentration in synapses. In such cases quetiapine helps in balancing dopamine levels leading to alleviation of psychotic symptoms. In one study, 200mg of quetiapine has shown efficacy with good tolerability in managing cases of cannabis use with associated withdrawl symptoms. Quetiapine has also been used in treating agitation in context of cannabis withdrawl. This effect is attributable to sedative property of quetiapine at lower doses. Considering the recent rise in cannabis use, various available literatures advocate for treatment strategy targeting the associated withdrawal symptoms but not cravings. Though, there is no recommended psychotropic medications for cannabis use disorder, quetiapine has shown efficacy in terms of ameliorating symptoms of agitation, insomnia, irritability and restlessness in context of cannabis use. This systemic review highlights the use of

quetiapine in cannabis use disorder in context of associated withdrawl symptoms and cravings.

No. 16

The Combination of Low-Dose Topiramate and Quetiapine in Chronic Alcohol Use Disorder: A Case Report

Poster Presenter: Muhammad Navaid Iqbal, M.D.
Co-Authors: Mehwish Hina, William Levitt, M.D., Rimon Levy

SUMMARY:

Alcohol use disorder carries significant morbidity and mortality impacting various psychosocial aspects including psychiatric and medical consequences. Maintaining abstinence from alcohol use with both psychotherapeutic and pharmacotherapeutic interventions stands out as the prime modality of management. This case report has shown safe and efficacious treatment in maintaining remission from alcohol dependence with low dose topiramate and quetiapine. This in contrast to the FDA approved medications, naltrexone, disulfiram and acamprosate, which did not show adequate response in this resistant case of alcohol use disorder. OBJECTIVE: The objective of this article is to report a case of alcohol use disorder that responded well with combination therapy of low dose topiramate and quetiapine enabling abstinence from alcohol use with significant reduction in frequency of cravings in the context of inadequate response to FDA-approved naltrexone and acamprosate for alcohol dependence. CASE: 31-year-old Hispanic Male with history of extensive alcohol use presented to our behavioral health outpatient clinic with frequent cravings for alcohol use along with subtle depressive and anxiety symptoms. Patient responded inadequately to monthly naltrexone injections leading to relapse on alcohol use. He was later switched to oral acamprosate with inadequate response on therapeutic dosing. He then, recommended with low dose oral topiramate (100mg) and quetiapine (150 mg), which led to significant alleviation of his cravings of alcohol enabling remission. This combination regiment was well tolerated. DISCUSSION: Review of available literature has shown that alcohol disrupts mesolimbic-dopamine pathway culminating into indirect release of dopamine via GABA system within reward system. Consistent stimulation of this pathway leads to positive reinforcement for alcohol use. Multiple studies have shown effective use of naltrexone, disulfiram and acamprosate in maintaining abstinence from alcohol use with substantial reduction in its cravings. Few articles support use of non- FDA medications like topiramate, quetiapine, and gabapentin. We have seen in this case how low dose combination therapy with topiramate and quetiapine helped this patient in maintaining remission from alcohol use along with significant reduction in symptoms of withdrawal. CONCLUSION: In this case report, we have observed how low dose topiramate along with quetiapine found to be effective in ameliorating cravings for alcohol use along with alleviation of subtle symptoms of depression and anxiety coexistent with it. This patient failed to maintain abstinence from alcohol use while on naltrexone and acamprosate at different times. The combined psychotherapeutic intervention enabled us to highlight alternate treatment modality in resistant cases of alcohol dependence.

Dual Cases: The Emergence of Substance Use Disorders Following Bariatric Weight Loss Surgery

Poster Presenter: Sameerah F. Akhtar, M.D.
Co-Author: Asghar Hossain, M.D.

SUMMARY:

We report two cases of female patients who developed substance use disorders within three years after bariatric surgery. One case of a 41 year old African American female who presented to the emergency room seeking treatment for alcohol and opioid abuse, as well as depressive symptoms. Patient reported she socially drank alcohol prior to her Bariatric surgery two years ago. After the surgery she was given opioid pain medication for post surgery pain. She developed opioid dependence and also start consuming alcohol daily which she attributed to her decreased appetite. The second case was a 37 year old Caucasian female who presented to the emergency room seeking treatment for alcohol, cocaine, and opiate abuse. She had bariatric surgery five years prior to presentation and also reports daily alcohol consumption only after the surgery. This patient was

also prescribed opioid pain medication and developed an addiction which several years later lead to intravenous heroin abuse. Cocaine was also used in increased amounts post surgery. In these cases both females claimed their daily substance use occurred post-bariatric surgery. Bariatric surgery, also referred to as weight loss surgery (WLS), is the most effective weight loss treatment for clinically severe or morbid obesity and has been gaining popularity (1). Physiological changes resulting from gastric bypass surgery may help to explain heightened postoperative alcohol sensitivity. Specifically, the portion of the stomach that secretes alcohol dehydrogenase, an enzyme that plays a significant role in alcohol metabolism, is circumvented following the procedure (2), and rapid emptying of the gastric pouch, particularly for liquids, facilitates quick absorption of alcohol into the jejunum (3). Opioids may be attractive to WLS patients because of their effects on the gastrointestinal tract, which counter those induced by WLS. In particular, opioids decrease gastric motility and increase transit time (4), which could conceivably mitigate adverse effects associated with post-WLS "dumping syndrome" (a condition characterized by dizziness, nausea, cramps, bloating, diarrhea, fatigue, shakiness, chills, and hot flashes, particularly following consumption of sweet foods).With this evidence it has been suggested the providers address these issues with patients prior to and following bariatric surgery to reduce the rates of substance use post surgical procedure.

Addressing the "Culture of Death": How Popular Media Has Glamorized Suicide Leading to Increased Suicide Attempts Among Teens

Poster Presenter: Sameerah F. Akhtar, M.D.
Co-Author: Asghar Hossain, M.D.

SUMMARY:

Suicide is the third leading cause of death among adolescents, accounting for a greater number of deaths than the next seven leading causes of death combined for 15- to 24-year-olds (1). Almost 1 in 12 adolescents in high school made a suicide attempt, and 17% of adolescents seriously considered making a suicide attempt, in the calendar year 2005 (2). In the United States, suicide rates doubled in the 15- to 19-year age group and tripled in the 10- to 14-year age group between the 1960s and the 1990s (3). Although the exact precipitant of these increased rates is uncertain it is largely believed that some of the contributing factors may be drug and alcohol abuse, unstable home environments, and lack of mental health treatment. More recently suicide has been glamorized in the media. A recent film "13 Reasons Why" depicts a teen who commits suicide after harassment and mistreatment by peers. Other examples include the more recent "Blue Whale Challenge" which is an online game centered around a curator that instructs individuals to perform stepwise tasks and ultimately leads to the final task of suicide. Social media outlets have also promoted "Killfies" which are photographs that encourage individuals to pose in risky and life threatening poses. Much concern has been posed on the impact of this form of media portrayal and how it will affect the rates of suicide in the teenage population. CONCLUSION: It is highly debated whether internet use and social media content plays an influential role on population suicide rates. Although limited, several preliminary studies have begun to address this topic. For example, Shah conducted a cross-national study that examined the association between general population suicide rates and the prevalence of Internet users, using data from the World Health Organization's and the United Nations Development Program's Web sites. Shah showed that the prevalence of Internet users was positively correlated with general population suicide rates (4). Another concern is the media contagion effect. (5-6). The media's influence on suicidal behavior, especially suicide methods used, has been well documented, and social media may possibly increase the risk of the media contagion effect, especially among young people. (7-8). A recent study by Dunlop, specifically examined possible contagion effects on suicidal behavior via the Internet and social media. Of 719 individuals aged 14 to 24 years, 79% reported being exposed to suicide-related content through family, friends, and traditional news media such as newspapers, and 59% found such content through Internet sources.(9) Younger people seem to be most vulnerable to the influence of the medi

The Role of Suboxone as a Treatmelnt Modality for Borderline Personality Disorder

Poster Presenter: Sameerah F. Akhtar, M.D.
Co-Authors: Ali Raza, Zohaib Majid, Asghar Hossain, M.D.

SUMMARY:

BACKGROUND Borderline personality disorder is characterized by dysregulation of emotion processing that manifest as affective lability and impulsive behaviors including aggression and self-harm. (3)The disorder is common in both the general population and in clinical settings. According to statistics in the point prevalence of borderline personality disorder in the United States is 1.6 percent in the general population and the lifetime prevalence is 5.9 percent (1) Psychotherapy is only partially efficacious and while patients may respond to medications there is no FDA approved medication for this disorder.(2) A 2010 review by Cochrane found that no medications showed promise for the core symptoms of borderline personality disorder including chronic feelings of emptiness, identity disturbances and abandonment but some medications have been helpful for isolated symptoms exhibited in this disorder (5). OBJECTIVE: The objective of this literature review is to investigate the role of the endogenous opioid system and its association with borderline personality METHOD: Literature from Pubmed, Uptodate, and The American Journal of Psychiatry were revised. CONCLUSION The dysregulation exemplified in borderline personality is characterized by short-duration, often severe, rapidly changing mood states that are highly reactive to environmental stimuli. Patients appear to react more quickly, with greater intensity and a slower return to baseline state endogenous opioid system. (3) A study suggested that the classic borderline personality symptoms which included risky sexual behavior, attention seeking may be explained by attempts to use the rewarding effects mediated by the endogenous opioid system. Anhedonia and feelings of emptiness may be an expression of reduced activity of the endogenous opioid system. Additionally patients with borderline personality tend to abuse substances that target mu-opioid receptors. The endogenous opioid system and ?-receptors are thought to be involved in borderline personality disorder because of increases in pain thresholds and dissociative phenomena that are reversed by opioid antagonists (4).Another study suggested the classic symptoms of borderline personality including risky sexual behavior, attention seeking may be explained by attempts to use the rewarding effects mediated by the endogenous opioid system. Anhedonia and feelings of emptiness may be an expression of reduced activity of the endogenous opioid system. Additionally patients with borderline personality tend to abuse substances that target mu-opioid receptors.(6). Though promising more data is however required to say with certainty if there is a definitive link between borderline personality disorder and endogenous opioid systems.

No. 20

Estrogen Therapy as an Adjunctive Treatment Modality in Schizophrenia

Poster Presenter: Sameerah F. Akhtar, M.D.
Co-Author: Asghar Hossain, M.D.

SUMMARY:

Schizophrenia is a neuropsychiatric disorder that affects thought, emotion, and behaviour with symptomatology being classified within three main clusters: positive symptoms, negative symptoms, and cognitive deficits (1). Positive symptoms include delusions, hallucinations, and disorganized thoughts while negative symptoms include apathy, anhedonia, social isolation, blunting of affect, and poverty of speech. Presently, the primary treatment for schizophrenia is antipsychotic medications, which predominantly target the dopaminergic system (2). Though antipsychotics have proven to be effective in the treatment of positive symptoms they are less efficacious in targeting negative and cognitive symptoms in Schizophrenia. Several characteristics have been closely observed in individuals with schizophrenia including the age of onset, symptomatology, and outcome of antipsychotic treatment differences between men and women (3). The estrogen hypothesis has been proposed to account for these gender differences and suggests that estrogen provides protection from the development of schizophrenia and mitigates the severity of negative symptoms (4). OBJECTIVE: The objective of this literature review is to investigate

the role of estrogen therapy as an adjunctive treatment modality in Schizoprenia METHOD: Literature from Pubmed and The American Journal of Psychiatry were revised. CONCLUSION: Although estrogen is known to be a female hormone its is present in different degrees in both sexes. Studies suggest that estrogen has neuroprotective properties. Accumulating evidence has led to the hypothesis that recurrent hormone influxes in women serve as a protective factor in the initial development of schizophrenia (4). Thus, in recent years an increasing amount of literature has explored estrogen therapy as a potential form of treatment for schizophrenia (5). One cross-sectional study compared postmenopausal women with schizophrenia who were either users or nonusers of hormone replacement therapy. They found that the women taking hormones required a lower dose of antipsychotics and had less severe negative symptoms (6). Variations in the menstrual cycle have also indicated improvement in positive symptom during periods where estrogen levels are higher. Though promising more data is required to say with certainty if there is a definitive indication for estrogen therapy as an adjunctive treatment modality for schizophrenia.

No. 21

Challenges of Treating Children and Adolescents With Gender Dysphoria

Poster Presenter: Azka Bilal, M.D.

SUMMARY:

I describe the case of a 15 year old female with depression and gender dysphoria, who presented to my outpatient clinic, after a recent suicide attempt. She reported symptoms of depression, and revealed that she had been struggling with gender identity and wanted to be a boy. She was having a difficult time gaining the support of the Catholic mother who could not believe how her daughter wanted to be a boy. She had taken the patient to multiple therapists prior to coming to see me, complaining how the "liberal" therapists were supportive her daughter's desire to be a boy rather than focusing on why she did not want to be a girl. Working in collaborating with the mother and treating the patient's depression made this case challenging. This case highlights the challenges encountered by the psychiatrist in treatment of patients with gender dysphoria. The role of a psychiatrist as an advocate for the patient is affected by his/her countertransference that in turn depends on his/her social, political and religious beliefs. Working with the family and their belief systems is another challenge. Moreover, psychiatric comorbidities and suicide risk can further complicate the treatment of the patient. Another important question for a child and adolescent psychiatrist is when is to refer their young patients for hormone or gender reassignment surgery.

No. 22

An Analysis of Juvenile Addiction Receiving Facility (JARF) Evaluations and Utilization of Inpatient Services for Miami Dade County

Poster Presenter: Elizabeth Hoy, M.D., M.S.

SUMMARY:

Co-Authors: Bryan Ellerson MD., Giannina Salas PsyD. Background: Substance abuse, and risky health behaviors among adolescents have become more prevalent in the United States population. Previous data has evaluated Juvenile Assessment Centers in Florida, and provided an overview of the services and procedures. Citrus Health Network (CHN) is the only Juvenile Addiction Receiving Facility (JARF) in Miami-Dade, and provides insight to the complexity of mental health and substance abuse interrelation, diagnosis and treatment in minority youth. Until we obtain better epidemiological data of adolescents being admitted to JARF, we cannot know how best to utilize the system's mental health and substance abuse resources. This study analyzed the JARF evaluations to further understand substance abuse and mental health in South Florida youth, among clinical sample of patients < 19 years old. Methods: A retrospective chart review was conducted on 706 admissions under JARF at CHN Inpatient Child Unit (August 2012 to December 2016). Data including the Global Appraisal of Individual Needs –Quick (GAIN-Q) instrument used for every JARF admission as well as demographic data from medical records were obtained to analyze patient population trends, and evaluate treatment recommendations. Factors affecting readmission were explored through contingency tables and the calculation of odds ratios. Results: Among 594 unique patients, 93

(15.7%) were readmitted to JARF center, and 14 (2.4%) patients had multiple readmissions. Of these patients, 389 (65.5 %) were male, 378 (63.7 %) were between age 16- 19 years, and 304 (60.7%) were Hispanic. Lifestyle data revealed that 584 (98.7 %) adolescents used any substance in the past 90 days. It was noted that 360 (60.6 %) patients have received some mental health treatment in past 90 days. In adjusted analysis, children ages 11-14 were more likely to be readmitted that children ages 16-19 (OR=3.32; 95% CI: 1.88-5.86), and those age 15 are 3.13 times more likely to be readmitted that children ages 16-19 (OR=3.13; 95% CI: 1.79-5.50). The odds of readmission increased for patients who had been arrested in the past 90 days by 66% when adjusted for other variables (OR=1.66; 95% CI: 1.01-2.72). Conclusions: Our results showed that in a predominantly Hispanic sample, the odds of JARF readmission were associated with age and arrest in the past 90 days. Population based data on these behaviors at the state, and local levels under JARF can help to understand the need for health interventions designed to protect and promote the health of South Florida adolescents. The identification of early life risk factors for JARF admission can inform both clinical professionals about children at risk for future admission and recognition that there is a shortage of community resources to address juvenile addiction.

No. 23

Retrospective Review of Prazosin Use in Adolescent Youth

Poster Presenter: Forrestine Dickson Knowles, M.D.

SUMMARY:

Introduction: The juvenile population has higher rates of multiple experienced traumas, and is thus at increased risk of developing Post Traumatic Stress Disorder (PTSD). In the general population, estimates of experienced trauma average 25% (Costello 2002), compared to approximately 90% in incarcerated youth (Abram 2004, Ford 2012). The American Academy of Sleep Medicine has recommended Prazosin as treatment for PTSD related nightmares (Aurora 2010). The most recent VA/DoD guidelines (2017) are equivocal regarding Prazosin's use in this manner. Although frequently used in the adolescent population, the evidence is limited to only a few case reports summarized by Akinsanya (2017), and a recently released retrospective chart review of patients treated in a trauma focused clinic (Keeshin 2017). Methods: After IRB approval, we conducted a retrospective chart review of youth evaluated and treated from June 2015 to June 2017 in a weekly juvenile detention center clinic. Utilizing the local EMR, a total of 167 patients were identified, of which 24 were found to have been treated with Prazosin. We reviewed gender, ethnicity, age at onset of treatment within the clinic, comorbid diagnoses, additional treatments, initial and final treatment dose, response, tolerability, and adverse effects. Results: SPSS was used to analyze data for relevant findings between the above variables. One patient was discharged prior to reassessment, and was thus excluded. The final N=23, 19 of which were found to have an improvement in symptoms (decreased number of nightmares). Overall, an overwhelming majority of patients demonstrated an improvement in symptoms, with mean dose of 2mg. The mean age at onset of treatment was 15 years old (yo) for responders and 16yo for non-responders. Four responders had significant tolerability issues. Of these four patients, 2 experienced symptomatic hypotension, 1 patient had asymptomatic hypotension and 1 experienced excessive sedation, influencing daytime functionality. Of these, only 1 of the patients with symptomatic hypotension elected to discontinue. One non-responder was found to have worsening of nightmares (quantity) and significant hypotension, therefore Prazosin was discontinued. Of note, multiple variables were reviewed to include gender, trauma type (physical, emotional, sexual), diagnoses (PTSD, ADHD, Mood Disorder, Substance Use Disorder), but no statistically significant findings were discovered as predictors of response to Prazosin. Conclusion: Within this limited data set, no statistically significant predictors of response (decreased nightmares) to Prazosin were found. However, given the overwhelming improvement in symptoms, we advocate for routine screening and careful consideration of trauma related diagnoses in high risk youth.

No. 24

Long-Acting Injectable Dopamine Neuromodulator Use in Pediatric Psychiatric Patients

Poster Presenter: Harsimran Kaur
Co-Authors: Astik Joshi, M.D., Shawn E. McNeil, M.D., Lee Stevens, M.D.

SUMMARY:
Background: Oral antipsychotics are the treatment of choice for a number of psychiatric disorders in children and adolescents, including schizophrenia, bipolar disorder. However, LAIs antipsychotics, including fluphenazine decanoate, haloperidol decanoate, risperidone microspheres, paliperidone palmitate, and aripiprazole monohydrate have not been approved for use in youth. Clinical applicability of LAI antipsychotics remains a global cause of concern. We undertook a review of the available literature to determine what the current state of knowledge for the use of LAIs in children and adolescents. Methods: Databases such as Pub med, CINAHL, Medline were searched for articles in English (2010-2017) using key words: long-acting injectable, antipsychotic, pediatric, bipolar, schizophrenia, psychosis. All research papers, review articles and articles published during the mentioned time were read and examined. Results: The search identified a number of case reports and series between 2010 and 2017; here we include two case series, one open-label trial, and one case report on LAI use in children and adolescents. Sample sizes with a total of 31 individuals were included in the reports. The age range was 11-17.These studies reported on a variety of conditions, including bipolar spectrum disorder, schizophrenia spectrum disorders, mood disorder NOS, and schizoaffective disorder, for which LAIs were adequate. LAIs antipsychotic use was recommended in patients with the following characteristics: multiple episodes and low adherence; serious episodes and multiple oral antipsychotic users still experiencing the symptom. Side effects, including weight gain, extra pyramidal symptoms, increased appetite and galactorrhea with LAIs appear similar to reports of side effects with oral drugs in young people with psychiatric conditions. Conclusion: The case reports and series reviewed highlight the efficacy and safety of LAIs for the treatment of serious mental illnesses like schizophrenia, bipolar spectrum disorder and schizoaffective disorder in children and adolescence. LAIs were effective in preventing non-adherence and in reducing relapse.

No. 25
Anxious School Refusal/Phobia: An Understudied Field
Poster Presenter: Jack Chengjie Wang, D.O.

SUMMARY:
Problem Statement: Anxious school refusal/phobia affects 2-10% of school-aged children each year. It can generate debilitating functional and psychiatric impairment. It usually suggests significant psychiatric comorbidities, and adverse experience at home and school. Psychiatric management is usually pragmatic. For evidence-based guideline, further research is required for this understudied field. Purpose: The purpose of this study is to illustrate two inpatient adolescent cases with debilitating school phobia, and to summarize literature review on child/adolescent school refusal/phobia. Methods: Two cases from child/adolescent inpatient unit are analyzed. Symptomatology and treatment strategies are compared with similar case reports and literature review findings. Literatures are searched using common web and scholar database queries, with both general and specific descriptors. Findings are synthesized in table and concept map format. Results: Two adolescents experienced similar hospital course with satisfactory initial response to integrated pharmaco-psycho-social intervention. Both adolescents felt reassured with their recommended flexible learning formats (home bound instruction or homeschooling). Literature review yield is moderate, with small scholarly studies and no landmark/classic article. Most treatment strategies are cognitive behavioral therapy based. Most studies failed to discuss home bound/homeschooling as a treatment strategy and one considered it as contraindicated. Conclusions: Anxious school refusal/phobia can generate severe functional and psychiatric impairment. It can have a bi-directional cause-effect relationship with comorbid psychiatric disorder, mostly depression and anxiety. It often suggests insidious psychosocial trouble at home or school. Its treatment strategies are mostly pragmatic. Home bound/homeschooling as effective intervention needs validation. Overall this field is understudied.

No. 26

Delayed Onset of Serotonin Syndrome in a 16-Year-Old Female After Intentional Sertraline Overdose

Poster Presenter: Jared Mendelsohn, M.D.
Co-Authors: Gabrielle Hodgins, Judith Regan

SUMMARY:

Background: Serotonin Syndrome (SS) is a potentially life threatening complication caused by increased serotonergic activity in the central and peripheral nervous systems. It is caused by excess stimulation of post-synaptic serotonin receptors and is characterized by the clinical triad of mental status changes, neuromuscular abnormalities, and autonomic hyperactivity. Over the past two decades, there has been an exponential increase in the use of psychotropic medications in the adult and pediatric populations. Much of this increase is owed to the popularity of Selective Serotonin Reuptake Inhibitors (SSRIs) and Serotonin Norepinephrine Reuptake Inhibitors (SNRIs) due to their broad range of clinical indications, relative tolerability, safety profiles, and wide therapeutic indexes. However, as the frequency of prescribing SSRIs to children and adolescents continues to increase, providers must be aware that these medications can cause serotonin syndrome, even as a single agent. Serum serotonin levels have not been shown to correlate with serotonin syndrome and the history and clinical presentation are used to make the diagnosis. Case: Here we present a novel case of serotonin syndrome in a 16-year-old female who intentionally overdosed on Sertraline in a suicide attempt. She was medically cleared at an outside hospital and transferred overnight to our child and adolescent psychiatry unit. The patient demonstrated a remarkably delayed onset of symptoms and only first began to exhibit jitteriness, tachycardia, and mild mental status changes the following morning at approximately 18 hours after ingestion. She was transferred to the pediatric medical unit where she subsequently developed visual hallucinations, disorganized thought process, severe agitation with physical aggression, increased tachycardia, mild elevation in CPK, hyperreflexia in the lower extremities, and inducible clonus. She was treated with IV fluids, Ativan 12mg IV in split doses during her first 24 hours on the pediatric medical unit, and Ativan 12mg IV in split doses over the next 24 hours on the pediatric unit. The patient's symptoms resolved on the fourth day after overdose and she was transferred back to the psychiatric unit where no further symptoms were observed. Discussion: This case adds to the literature of serotonin syndrome caused by overdose of an SSRI as a single agent in the child and adolescent population. Moreover, it suggests the possibility of a delayed onset of clinical symptoms of serotonin syndrome and the need to observe or monitor patients for 24-48 hours after an SSRI overdose.

No. 27

Schizotypal Personality Disorder in Two Children on an Acute Inpatient Psychiatric Unit: Potential Risks, Manifestations, and Concerns

Poster Presenter: Javier Reyes, M.D.
Co-Authors: Judith Regan, Samantha B. Saltz, M.D.

SUMMARY:

Diagnoses of conduct disorder, antisocial personality disorder, and comorbid substance use with access to firearms have been frequently linked to adolescent perpetrators of mass school shootings in North America. Less frequently, Schizotypal personality disorder has been mentioned as a risk factor. Individuals with schizotypal personality disorder are described as strikingly odd and commonly exhibit magical thinking, peculiar speech, disturbed thinking, interpersonal difficulties and social isolation. A 2004 study showed that ''odd, reclusive and dramatic acting-out patterns of behavior" were suggested in a majority of adolescents who became mass murderers (Meloy et al., 2004).We believe that further investigation is needed to explore the association of schizotypal personality and mass homicide by adolescents. Methods: We present two adolescents hospitalized in an acute inpatient child and adolescent psychiatric unit with homicidal ideation. Results: Case 1 : A 14-year-old male was admitted to an acute inpatient psychiatric unit after suggesting to classmates that he was considering shooting other children at school. He told classmates to wear white in order to avoid being shot. He also threatened that he would commit suicide on social media. Projective data suggested that the patient was experiencing disorganized thinking often grounded in fantasy rather than reality. He displayed odd thought patterns and a preoccupation with horror films and fantasy. He exhibited a rigid style of

thinking regarding emotions and relationships and was found to be impulsive. Case 2: A 16-year-old male was admitted to an acute inpatient psychiatric unit after telling his father that “he was going to make Columbine look like a joke.” He admitted to watching documentaries about the Columbine school shooting and posting a note on a school website stating that he would “shoot up the school” and then kill himself. MACI was administered showing a low Desirability Scale Score (BR=35) and a Debasement Scale Score (BR=72) indicating a tendency to devalue himself. He received elevated scores on Introversive (BR= 83), Doleful (BR= 77), Inhibited (BR=74), Submissive (BR =74), and Self-Demeaning (BR= 72) scales. Projective drawings suggested insecurity and rigidity patterns with a severe sense of inadequacy, helplessness, and seeing the world as unkind. The Rorschach Inkblot test showed a propensity to lose contact with and distort reality when under perceived immense stress. Conclusions: We present two adolescents admitted to an inpatient psychiatric unit after making mass homicidal threats towards classmates followed by suicidal ideation. Both were diagnosed with schizotypal personality disorder. While other personality traits and risk factors have been more commonly linked to mass school shootings, we intend to further explore the potential risk for this behavior and possible interventions in children diagnosed with schizotypal personality disorder.

No. 28

Child Abandonment in the Psychiatric Emergency Department

Poster Presenter: Jessica Ee, M.D.
Co-Authors: Maura Hanna, Robert L. Weisman, D.O.

SUMMARY:
New York State law classifies a child as abandoned if the guardian “forego[es] his or her parental rights and obligations as manifested by his or her failure to visit the child and communicate with the child although able to do so.” Resident physicians within a university psychiatric emergency department have noticed a significant increase in child abandonment cases involving children with developmental disabilities or autism spectrum disorders. Although several of these children were connected to multiple community and government services, their complex needs failed to be met, prompting emergency department presentations for chronic behavioral issues. Behaviors not improved, and typically worsened, during inpatient admissions. Though cleared for discharge, these individuals are left for days in an acute emergency department setting without a legal status to retain them, yet lack the capacity to leave. These children require intensive staff support at an expense greater than the average $1300/emergency department visit covered by insurance. The cases are reported to Child Protective Services, but this leverages little support or incentive for families to bring their children home. This case report describes one patient abandoned in the psychiatric emergency department repeatedly and illustrates several of the legal, community and systems based issues confronting families, patients and emergency department services as well as highlights changes that need to be made in future to care for children with developmental disorders.

No. 29

Treatment Challenges and Risks of Polypharmacy Among Adolescent With Mental Disorder in Juvenile System: A Case Report

Poster Presenter: Jin Cai, D.O.
Co-Author: Garima Singh, M.D.

SUMMARY:
Abstract This is a case of a 17 year old male with a diagnosis of Autism Spectrum Disorder, Psychosis Disorder Unspecified, Intermittent Explosive disorder, and Intellectual Disability who was in juvenile system and seen through telehealth. At the initial visit, patient was prescribed three antipsychotics, one mood stabilizer, and a medication for insomnia: 3 mg Risperidone BID, Chlorpromazine 50mg BID, Quetiapine 100mg QHS, Depakote 500mg TID, and Trazodone 50mg QHS. Patient presented somnolent on these medications and was unable to complete his daily activities. Due to the concerns for the safety, long term side effects, risk of polypharmacy (i.e. three antipsychotics) and the fact that the patient was having issues completing daily activities due to somnolence was planned to taper down to two antipsychotics. When the patient was tapered down on Quetiapine, started to have increased auditory hallucinations the patient was sent to inpatient facility for further

evaluation and stabilization. Risperdal was tapered off while increasing in Divalproex Sodium, Chlorpromazine, and Quetiapine. Also, the patient was cross tapered off trazadone and started on Prazosin and Citalopram. Patient tolerated the change well and showed improvement in cognitive state throughout hospitalization. The patient was discharge back to the juvenile system with much improvement in behavior, minimized auditory hallucinations, and day time somnolence. Patient was stabilized on Divalproex Sodium 475mg TID, Chlorpromazine 25mg BID & Chlorpromazine 100mg QHS, Quetiapine 300mg BID, Citalopram 15mg Daily, and Prazosin 2mg QHS. The problems encountered in this case include psychosis, unstable living situation, Autism Spectrum Disorder, and aggressive behavioral concerns. In conclusion, there continues to be a minimal amount of literature about the prescription drug use and the rates of polypharmacy in the treatment of children/adolescent in the Juvenile system. Few studies have shown that adolescents in the juvenile system are at higher risk for polypharmacy, up to ~50%. Clinician needs to be more aware when treating those in the juvenile system because these patients usually require lifelong treatment and are at higher risk of extrapyramidal symptoms, akathisia, sedation, weight gain, and/or metabolic syndrome due to polypharmacy. Prescribers and caregivers should be encouraged to weigh the benefits and risks associated with pharmacological treatment. Case management should include good coordination of care with primary care provider, therapist, and social services for the efficacious and successful management of the adolescent patient.

No. 30

Parenting Style and Mental Disorders in a Nationally Representative Sample of U.S. Adolescents

Poster Presenter: John Eun

SUMMARY:

Purpose: We examined associations between parenting style and past-year mental disorders in a nationally representative sample of U.S. adolescents and whether the associations differed by adolescent demographic characteristics. Methods: The sample included 6,483 adolescents aged 13 to 18 years who were interviewed for a full range of DSM-IV mental disorders. Parenting style was assessed by adolescent-reported maternal and paternal care and control using items from the Parental Bonding Instrument. We controlled for socio-demographics, parental history of mental disorders, stressful life events, sexual violence, inter-parental conflict, and household composition. We also tested for two-way interactions between parental care and control and adolescent age, sex, and race/ethnicity. Results: In adjusted models, high maternal care was associated with lower odds of depressive, eating, and behavioral disorders, and high maternal control was associated with greater odds of depressive, anxiety, eating, and behavioral disorders. High paternal care was associated with lower odds of social phobia and alcohol abuse/dependence. High paternal control was associated with greater odds of agoraphobia and alcohol abuse/dependence but with lower odds of attention-deficit/hyperactivity disorder. Associations of maternal and paternal control with anxiety disorders and substance abuse/dependence differed by sex. High paternal care was associated with lower odds of anxiety disorders only among Hispanics and non-Hispanic blacks. Conclusions: Parental care and control were associated with adolescent mental disorders after controlling for multiple potential confounders. Differential patterns of association were found according to adolescent sex and race/ethnicity. Findings have implications for prevention and intervention programs that incorporate familial contextual factors.

No. 31

The Trend Toward the Prescription Drug Misuse: A Case of Xanax Addiction in Child

Poster Presenter: Ketan A. Hirapara, M.B.B.S.
Co-Authors: Bimla Rai, M.D., Rashi Aggarwal, M.D.

SUMMARY:

Introduction: Knowing the fact that their own child has been misusing prescribed drugs is always devastating for any parents. Sedatives including Xanax (Alprazolam) are widely used for treatment of insomnia and anxiety by physicians but they have high misuse and abuse potential. This not only concern for addiction or misuse potential in adults but also in children. According to Forbes, estimated 50 million prescriptions of Xanax was prescribed in

2013. Xanax is the number one prescribed psychiatric medication in the United States. According to SAMSHA, in 2015 an estimated 1.5 million (6.6%) children aged 12-17 misused Xanax of total 1.6% who misused tranquilizers. According to National Institute on Drug Abuse, 1.70% 8th graders, 4.10% 9th graders and 4.90% 10th graders misused tranquilizers including Xanax. Survey by teen treatment Center showed that 9% of highschool children in the US reported abusing Xanax at some point in their life. There hasn't been any case reported despite increasing incidence of Xanax misuse or abuse. Case Report: A 11 year old girl was referred to emergency room for her school for an evaluation for drowsiness. While individual interview with patient, patient reported that past few weeks she has been using Xanax on and off. She was getting Xanax pills from her friend who was getting it from his mom's medicine cabinet. Friend himself was misusing it. When asked about the reason, she reports that she was stressed out, resulting in first time use when offered by her friend. First experience of high feeling lead patient to get more Xanax from friend. On the day of ED visit, she reported one pill resulting in no high effects so she use one after another 3 more doses and she became drowsy. When informed parents about her Xanax use, they were shocked as reported being aware of whole scenario. Discussion: Despite, well known fact of prescribed Xanax misuse in children, very few has been published about it. Not just awareness among parents to identify Xanax abuse symptoms in their children such as mood swings, neglecting school and other responsibilities, extreme tiredness, changes in friends, stealing money from family and friends, suspicious behavior but also risk stratification by prescribing physicians by discussing associate misuse in kids while prescribing are important elements and they have never been addressed so far, justifying further awareness to optimize alternative treatment, patient risk assessment, establishing a treatment plan and limiting dose & early refills. More concerning is subtle effects on motor skills, cognition, memory as children's' brain are not fully developed. Data showed that 53.7% of children get the drug from family & relatives, 34% get from doctor or stole from health care providers. As a parent if suspected avoid false sense of security and "TALK TO YOUR CHILD."

No. 32

Stirring the Melting Pot: Introduction of Practice-Based Module to the Cultural Competency Training for Psychiatry Residents

Poster Presenter: Alaa Elnajjar, M.B.B.Ch.
Co-Authors: Hameed Azeb Shahul, M.B.B.S., Alexander C. L. Lerman, M.D.

SUMMARY:

The role of culture in the assessment and care of psychiatric patients has been written about at length, is often emphasized in principle, and yet overlooked in clinical practice. Considerable evidence supports the idea that sociocultural differences between patients and physicians can influence communication and clinical decision-making. A literature review suggests that, residency training to deliver effective care to people of various sociocultural backgrounds lags behind other clinical/technical areas. Studies on implementation and resident preparedness indicate that much of the experience acquired by resident's stem from the understanding/skills they develop on their own from clinical experience, as opposed to be the result of formal training. In a National survey of 2047 resident, 96% agreed upon the significance of addressing the cultural dimension of health care. A large percentage indicated that they were not well prepared to care for patients with health beliefs at odds with Western medicine (25%). We plan to explore the significance of practice-based learning as part of the cultural competency curriculum. Videotaped culturally challenging scenarios of standardized patients will be created. The residents in the program will be asked to build a cultural formulation after the interview. These videos are designed to improve the trainee's ability to carry out a culturally competent interview, with special focus on the components of resident preparedness – namely, knowledge acquisition, skills training and development of the right attitude. These videos will also touch upon various elements of a profound culturally relevant clinical evaluation, such as the implications of linguistic barrier, patient's perception of illness, his/her reaction and adjustment to illness, body language and demeanor, motivation for treatment/compliance, and other perceived idiosyncrasies during an interview. It will also

explore the physician's potential biases during an evaluation of someone from a different culture. Assessment of the learning experience will be done through a special rating scale tool, which is designed to evaluate the interviewer's cultural competency; his/her capacity to be empathic and establish rapport; the use of advanced interview techniques such as confrontation and formula-driven interviewing, and the awareness of one's own emotional response or countertransference.

No. 33

Characteristics of Patients With Frequent Readmission to Child and Adolescent Inpatient Units: Predictors for Better Quality of Care

Poster Presenter: Alaa Elnajjar, M.B.B.Ch.
Co-Authors: Ifeoluwa Osewa, M.D., M.P.H., Shanila Taha, Steven G. Dickstein, M.D.

SUMMARY:
Readmission is defined as patients being readmitted to any psychiatric inpatient setting within 30 days of discharge from an inpatient psychiatric setting. Previous studies showed Child and Adolescent re-hospitalization rates range between 19%-28% within six months (Arnold et al., 2003), 38% within one year (Fontanella, 2008), and 43% within 2.5 years after discharge (James et al., 2010). At Westchester Medical Center (WMC), a tertiary care academic hospital in Westchester, New York, readmission rate for child and adolescent units over an 18-month period (Jan. 2016- June 2017) was 31.8%. Literature reviews have identified various characteristics that are more common among people who utilize heavier use of inpatient psychiatric services. In our clinical practice, we have observed several factors possibly contributing to readmissions, including: medication adherence, patient/caregiver education, transitional care planning, discharge disposition, and recurrent suicidal/self-injurious behavior. This study was designed to determine and quantify these factors, which will allow the identification of targeted approaches to reduce frequent readmissions. The research is phase one of a quality improvement project, performed by the Behavioral Health Readmission Reduction Committee at WMC, in collaboration with the Westchester County Office of Mental Health (OMH).Methodology: The study is an observational chart review at WMC. Data were retrospectively reviewed from January 2016 to June 2017. A total of 106 cases who had re-hospitalizations within 30 days of their last discharges were eligible for the study. A set of clinically relevant predictors was generated based on a literature review. Data Abstraction: The selection of target population and data was extracted from: The electronic medical records of WMC and Behavioral Health Center (BHC), Clinical Record Interactive Search (CRIS), Net Access, and PSYCHES for Medicaid patients. Variables were identified utilizing the emergency department review of charts and post-discharge services. These variables include but are not limited to socio-demographic factors, medication upon admission and discharge, prior hospitalization, length of stay, diagnosis, substance abuse, history of suicidal attempts, history of violence, living situation, post-discharge communication, and insurance status. It is hoped that by analyzing the available data, specific variables will be identified to allow clinicians to predict which patients are at higher risk for readmission. In phase two, we will address the provider and system factors and design interventions to evaluate and improve readmission rates. Results: Currently pending Institutional Review Board (IRB) review, data will be ready by the time of the poster presentation.

No. 34

Current Trends in Cognitive Enhancement Therapies of Schizophrenia

Poster Presenter: Jaskirat Singh Sidhu, M.D.
Co-Authors: Fei Cao, M.D., Ph.D., Javeria Sahib Din, Ambika Kattula, M.B.B.S.

SUMMARY:
Background: Schizophrenia is characterized by broad cognitive decline, including impairments in memory, attention, executive functioning, vocabulary, visuospatial skills and learning. Unfortunately, all antipsychotics available at present provide little help in cognitive impairment associated with Schizophrenia (CIAS). As a result, new treatments are needed to better control CIAS. Briefly, current strategies targeting cognitive deficits broadly consist of pharmacologic agents and cognitive re-training. Pharmacologic agents: TC-5619 (?7 nAChR Agonist), had effectively improved executive functions and

negative symptoms in the clinical trials; both Tandospirone (5HT-1A rec agonist) (given alone or in combination with antipsychotic blonanserin) and Positive allosteric modulators (M4 mAChR agonists) had demonstrated efficacy in treating cognitive deficits in the animal models; Modafinil also improved cognition in sleep-deprived patients in the clinical trials; Inhibition of phosphodiesterase 10A (PDE10A) activates dopamine D1, and were currently under study to improve cognition in Schizophrenia; Estrogen based therapies were also beneficial. Non-pharmacologic therapies/CET: Verbal learning had proven benefits in restoring cognition; Targeted cognitive training of auditory processing was associated with better executive functions but not verbal memory; Aerobic exercise induced increased neuroplasticity improved the functioning and cognition; Cognitive remediation and concurrent psychosocial therapies had been noted to help improve functioning and cognition in schizophrenics; Cognitive enhancement therapies had also shown to increase the neural activity in the brain confirmed by MRI studies and had been effective in improving negative symptoms and executive function; Increased social interaction of the patients in the group homes had enhanced effectiveness of cognitive enhancement therapy (CET); Transcranial stimulation was another common option but more evidence is required to prove its efficacy. Method: The objective of this review is to highlight current trends in targeting CIAS. Journal articles from PubMed and Cochrane from the past five years regarding advancements to improve cognition in schizophrenic patients are systematically analyzed. All these new interventions will be discussed in terms of their efficacy. Conclusion: The pathophysiology of all domains of Schizophrenia is divergent. As a result, the exact causes and etiologies of cognitive decline in schizophrenia is still an area of intensive research. Pharmacological and non-pharmacological methods targeting specific connections among these different domains can be interesting and unexplored starting points.

No. 35

Residency Characteristics That Matter Most to Psychiatry Residents: A Multi-Institutional Canadian Survey

Poster Presenter: Jennifer Wong, M.D.

SUMMARY:

Background Residency is a critical period for the psychiatric trainee. It is important for residency teaching programs to understand what characteristics influence the prospective resident to further advance residency education. The richness of the residency experience is often tied to resident satisfaction. Resident satisfaction is not only an indicator of the quality of clinical education but frequently impacts a resident's overall wellbeing. Objective: To investigate what factors correlate with a psychiatric resident's satisfaction in determining a successful residency experience. Methods: An online, anonymous cross-sectional survey was developed and sent to all psychiatry residents in Canada, approximately 750 residents, through the Coordinators of Psychiatric Education (COPE) at each program to be distributed at their discretion. Survey responses were linked to their respective institutions (N=6). The survey included resident and residency demographics, as well as subcategories focusing on research, education, call duty, teaching opportunities, faculty, and residency culture. Satisfaction of the residency program was rated on a 7-point Likert scale. Statistical significance was determined using multiple response analysis in SPSS. Results: One hundred and forty two psychiatry residents responded to the survey. Overall, 83.8% (118/142) residents reported being 'very satisfied' (57.0%) or 'moderately satisfied' (26.8%) with their program. In comparison, 4.2% reported they were 'moderately dissatisfied'; 10.6% reported being 'slightly dissatisfied', 'slightly satisfied' or 'neutral'. Conclusion: Our study adds to the existing body of literature offering insight into factors that contribute to the quality of psychiatry residency programs.

No. 36

See One, Do One, Document One: Improving Resident Physician Clinical Documentation Skills Through Education and Example

Poster Presenter: Lauren Marie Pengrin, D.O.

SUMMARY:

Clinical documentation is an essential component of patient care, especially in psychiatry. Psychiatrists, more so that many other specialties, rely on medical records to capture the nuances of patient

interactions. It is one of the key ways in which we communicate our findings and intentions with other health care professionals. Resident physicians are responsible for a large percentage of the documentation in hospitals across the country. This presentation will discuss the importance of proper education for psychiatric resident physicians in the art and science of utilizing electronic medical records to provide the best patient care and outcomes. It will outline current documentation curricula and expected competencies as defined by the ACGME. Additionally, this presentation will propose improved curricula and education modules designed to more fully prepare psychiatric resident physicians for the rigors of documentation in the electronic medical record era. The aim of these revamped modules is to ensure accurate and thorough charting and billing, while avoiding the potential pitfalls of "check list" documentation. Finally, this presentation will also explore the role of supervising and teaching physicians in resident education and suggest ways to best impart the necessity of precise documentation through example.

No. 37

An Evaluation of Empathy Within a Psychiatry Residency Training Program

Poster Presenter: Luciana Giambarberi, M.D.
Co-Author: James N. Kimball, M.D.

SUMMARY:

Background: Despite evidence for the centrality of doctor–patient relationships in effective psychiatric treatment, the current research paradigm of psychiatry has paid limited attention to the role of empathetic human understanding in routine psychiatric treatment. Psychiatry has faced significant criticism for excessive dependence upon the Diagnostic and Statistical Manual of Mental Disorders (DSM) and medications while disregarding empathetic, humanistic interventions. Helping those with mental illness involves the use of empathetic skills throughout practice. However, there is little discourse on how empathy can be effectively incorporated into daily practice. The Helpful Responses Questionnaire (HRQ) is designed to measure the development of reflective listening and empathy skills. These skills are central to the implementation of motivational interviewing in mental health, addiction and social service settings. The HRQ has also shown promise in the clinical years of medical training. This instrument demonstrates strong potential for use as a tool that measures effectiveness of motivational interviewing in a longitudinal curriculum, addressing client and patient behavior change across multiple healthcare settings. While other validated empathy questionnaires exist, the HRQ is unique in that the respondent is required to provide free form answers, as opposed to answering on a Likert scale. There are limited studies using the HRQ, particularly in psychiatry residents. This study is designed to evaluate empathy in psychiatry residents at an academic medical center in the Southern United States. One hypothesis is that empathy is dependent on level of training. **Methods:** Psychiatry residents and fellows at Wake Forest Baptist Medical Center were surveyed via email. They were provided with the HRQ and explanation that their responses could lead potential future research projects. Scores were assessed using a 5-point ordinal scale of depth of reflection (5 being the highest empathy rating, 1 being the lowest) and cross-referencing "Thomas Gordon's Twelve Roadblocks." **Results:** 24 out of 32 residents responded. A brief summary is shown below: PGY-1 PGY-2 PGY-3 PGY-4 PGY-5 Avg. HRQ Scores: 1.5 1.7 1.6 1.9 3.9 **Conclusion:** There is a correlation between higher HRQ empathy scores and increasing years of training. However, overall, especially within the first 4 years of training, scores are low. PGY-5 fellows had notably increased empathy scores. Continued research and analysis is warranted in order to further elucidate significance among training levels. Subsequent stages of this research will include: expansion of the HRQ survey to include all psychiatry residents in the U.S., empathy training at Wake Forest to assess for potential improvements in empathy scores and surveying residents in all departments at Wake Forest to assess for variations among specialties.

No. 38

Teaching Neurobiology in Psychiatry

Poster Presenter: Lujain Alhajji, M.D.

SUMMARY:

The relationship between psychiatry and neuroscience has constantly evolved since the

conception of our field. The past two decades have witnessed a steep rise in research related to neurobiology in psychiatry. Advances in neuroscience have led psychiatry residency programs to steer towards a neuroscience based approach instead of the traditional focus. Despite increased interest and advances in neuroscience and psychiatry, residency programs are not required to integrate neurobiology in psychiatry. There are several difficulties residency programs face when attempting to teach this subject area, including the availability of knowledgeable faculty, knowing what to teach, and how to deliver the information. Psychiatrists across all levels of training are enthusiastic about learning neuroscience. With the current advances in biological psychiatry, neurobiology needs to be integrated into the training and teaching of psychiatry residents. The approach of integration has to be transdiagnostic, clinically relevant and applicable to both trainees and psychiatry educators. We will discuss the importance of teaching neurobiology in psychiatry residency programs, outline specific areas we recommend teaching, and propose teaching strategies that may enhance learning by psychiatry residents. The neurobiology topics we recommend for psychiatry programs to teach their residents include: neuroscience literacy, neuroanatomy, neuroimaging, neuropathology, neural circuits and neurotransmitters, neuroendocrinology, psychoneuroimmunology, neurophysiology, genetics and epigenetics, and neuropsychological testing. There are different strategies to teach residents that enhance adult learning, which include formal discussions, clinical case presentations, journal clubs, specialized neuroscience rotations, neuroanatomy modules, grand rounds and classes discussing topics at the interface of neuroscience and psychiatry in the media.

Suicide Conduct Among Students: The Biggest Challenge in College

Poster Presenter: María Morel
Co-Author: Moises Zouain

SUMMARY:

Background: Mental illnesses, mainly depression and alcohol consumption disorder, substance abuse, violence, feelings of loss and diverse cultural and social environments are important risk factors of suicide. This study determined the prevalence and factors associated with suicidal behavior in university students. **Methods:** A cross - sectional descriptive study of primary source was carried out, where the population investigated were 412 undergraduate students of the Pontificia Universidad Católica Madre y Maestra (PUCMM), Santiago, Dominican Republic, during the second trimester of the 2016–2017 academic year. The questionnaire consisted of 59 questions, conducted by the researchers. The data collection instrument includes the Beck Despair Scale, the Plutchik Suicide Risk Scale and the Family Apgar, as well as questions about sex, academic career, alcohol and tobacco use, sexual abuse, sexual preferences, among others. **Results:** Plutchik's suicide scale revealed that 22% (IC95%=17.9%–25.8%) of the participants was at high risk of committing suicide. At the same time, Beck's scale of hopelessness showed that 26% (IC95%=21.7% - 30.2%) of the students had suicide conduct. There was a statistically significant relationship between the college career, sexual identity, career change and family dysfunctionality with suicidal behavior according to the Beck Despair Scale. **Conclusion:** There is a high prevalence of suicidal behavior in university students. Sexual identity, visits to the counseling department and different reasons, and family dysfunction are related to suicidal thoughts or behavior. **Keywords:** Suicide, Collegue Students, Suicidal Behavior, Psychiatric Disorders

Using I-PASS in Psychiatry Transitions of Care

Poster Presenter: Michael Reid Bowes, D.O.
Co-Author: Landon S. Frost

SUMMARY:

Limitations placed on resident duty hours in recent years were instituted primarily to improve patient safety; however this has also inadvertently created a new opportunity for adverse outcomes through an increased number of handoffs. I-PASS (illness severity, patient summary, action list, situational awareness with contingency planning, and synthesis by the receiver) is a handoff system that has been used in multiple specialties with significant success.

There is very little research about handoff tools in the psychiatric field specifically, and this article describes how our medical center has instituted this new protocol with a lot of success in three diverse psychiatric settings. In this article we discuss the format of I-PASS, and how it can be incorporated into a residency program to help fulfill residency requirements as well as provide a superior education for future psychiatrists.

No. 41

The Effect of Administering a Boundary Course to Third Year Medical Students During Their Psychiatry Clerkship

Poster Presenter: Michael Hidalgo
Co-Authors: Sindhura Kunaparaju, M.D., Karim W. Ghobrial-Sedky, M.D., M.Sc.

SUMMARY:
Due to their lack of experience, third year medical students (MS3) are most vulnerable to boundary violations. Investigators aimed to increase awareness regarding boundary issues among MS3s and to assess the effect of videotaped scenarios followed by case based discussion on medical students' comfort in managing boundary issues with patients.A nine question pre-course survey was administered to all MS3s enrolled at Cooper Medical School of Rowan University that asked students to rate their comfort in managing various boundary challenges. MS3s viewed seven pre-recorded simulated boundary-related cases followed by a 10-15 minute discussion of each case that was facilitated by the clerkship director. A post-course survey included three additional questions to the pre-course nine questions to assess students' satisfaction with the course. Pre- and post-course scores were analyzed using Paired t-Tests and effect sizes (ES) were reported. There was a statistically significant difference between the pre-and post-course scores for seven of the nine survey questions, with large ESs (above 0.8) observed for those questions. There was no statistical difference in offering handshakes or giving money to patients. Overall, these findings indicate that students were more comfortable managing the selected boundary issues following the course. In addition, the course was perceived favorably by MS3s. Medical students perceived the course to be beneficial and reported that it increased their awareness to boundary related issues. A boundary course at the beginning of the Psychiatry clerkship improves MS3s comfort in managing boundary challenges with better focus on safety, confidentiality, and building a therapeutic alliance with their patients.

No. 42

Psychiatric Manifestations of Arnold Chiari Malformation

Poster Presenter: Hector Cardiel Sam, M.D.
Lead Author: Aamani Chava, M.D.
Co-Authors: Asghar Hossain, M.D., Javeria Sahib Din, Zohaib Majid

SUMMARY:
The purpose of this case presentation is to illuminate a link between Arnold Chiari malformation, its treatment and psychiatric sequelae. We relay the case of CK a child who was born with Arnold Chiari malformation who recently underwent surgical treatment, after which she began to display behavioral disturbances most consistent with bipolar one disorder. We seek to establish the link between Arnold Chiari malformation and psychiatric manifestations along with the residual effects of surgery. Through a literature review we conclude that there is indeed a link between ACM and psychiatric illness that must be studied further.

No. 43

Factitious Disorder in Medical Professionals

Poster Presenter: Hector Cardiel Sam, M.D.
Lead Author: Sheema Imran, M.D.
Co-Authors: Asghar Hossain, M.D., Javeria Sahib Din, Zohaib Majid, Muhammad Navaid Iqbal, M.D.

SUMMARY:
This case report seeks to examine the nature of factitious disorder in medical professionals and subsequent comorbidity. We relay the case of GA a former internal medicine resident who lost his career do to self prescribing medication for an undiagnosed case of ADHD and later began to experience insidious neurological symptoms which after multiple costly medical work ups did not yield a definitive diagnosis. Through literature review we elucidate the most common presentations of factitious disorder and the most common

comorbidities amongst those in and near the medical profession.

No. 44

Personality Disorders and Early-Life Trauma

Poster Presenter: Hector Cardiel Sam, M.D.

Co-Authors: Asghar Hossain, M.D., Aamani Chava, M.D., Naveed Butt

SUMMARY:

Personality of a specific individual can be defined as a set of individual differences that is, long term tendencies to think, feel, and act in a particular way. In the following case series we explore the genetic, neonatal, and environmental factors in early life that lead to the development of personality disorders. We explore the cases of several patients who suffered neonatal insults and early childhood trauma who later developed personality disorders. Through literature review we seek to establish potential causes of the development of personality disorder and seek to formulate further research directions to explore the development of personality disorders.

No. 45

Early Life Insults and Later-Life Psychiatric Manifestations

Poster Presenter: Hector Cardiel Sam, M.D.

Co-Authors: Asghar Hossain, M.D., Aamani Chava, M.D., Naveed Butt

SUMMARY:

In this case study we seek to establish the link between neonatal insults/early childhood insults and the development of psychiatric illness later on in life. We relay the case of a child DO who suffered multiple developmental insults in her childhood. In the neonatal period she suffered through persistent substance abuse. In her childhood she suffered through neglect and multiple traumatic experiences with DYFUS removing her from her birth mother twice. In her adolescence she has received a diagnosis of ODD and has multiple inpatient psychiatric admissions do to aggressive and assaultive behavior towards her mother. Through literature review we conclude that early life insults lead to a variety of psychiatric manifestations later in life.

No. 46

Pseudocyesis Versus Delusional Pregnancy: The Gendering of Psychosis

Poster Presenter: Hector Cardiel Sam, M.D.

Lead Author: Sheema Imran, M.D.

Co-Authors: Asghar Hossain, M.D., Javeria Sahib Din, Muhammad Navaid Iqbal, M.D., Nirali Dave

SUMMARY:

This case report seeks to establish the causes of pseudocyesis in the context of socioeconomic stressors and maternal loss. We relay the case of ML, a 25 YO F with a significant past psychiatric history who five months prior delivered and lost custody of him. Since that time the patient has been insistent that she is pregnant despite multiple negative HCG tests. The patient continues to claim she is lactating and that she is still 'showing'. Through extensive literature review we also seek uncover gender biases and cultural norms that skew psychiatric delusions towards the feminine. We establish a causal link between maternal loss and pseudocyesis.

No. 47

Can Pharmacogenetic Testing Lead to a False Sense of Security in Clinical Decision-Making? A Case of Nortriptyline-Induced Brugada Syndrome

Poster Presenter: Aaron Wolfgang, M.D.

Co-Authors: Sean Lowell Wilkes, M.D., M.Sc., Iqbal Ahmed, M.D.

SUMMARY:

Introduction: The landscape of psychiatry has taken an important step forward towards personalized medicine with the advent of pharmacogenetic testing. Although pharmacogenetic testing for CYP450 enzymes has been FDA-approved since 2004, its utility in clinical practice and in improving patient outcomes continues to be debated. Though pharmacogenetic testing may bring added value in guiding clinical decisions, it also brings the added potential for unforeseen pitfalls that may ultimately lead to patient harm. Case: "Jane" is a 17-year-old female with a history of treatment-refractory major depressive disorder and chronic migraines. Due to being found that she was an ultrarapid metabolizer of 2D6 on pharmacogenetic testing, her nortriptyline – a major 2D6 substrate – was increased from 75 mg

daily (serum concentration of 53 ng/mL) up to a total daily dose of 225 mg, titrated to a therapeutic level of 101 ng/mL. Over the next 6 months, Jane was also started on bupropion XL 150 mg daily – a strong 2D6 inhibitor – amongst a number of other non-contributory medications. Her bupropion was later increased to 300 mg daily. There was no further therapeutic drug monitoring of her nortriptyline levels as these additional medications had been added to her regimen. One week after the increase in her bupropion dosage, Jane had a 30-second episode of loss of consciousness and tonic-clonic activity which was later determined to be an aborted sudden cardiac death. She was then admitted whereupon her EKG was found to be indicative of Brugada Syndrome – a rare sodium channelopathy that can be induced by tricyclic antidepressant toxicity among a host of other etiologies and which often leads to ventricular arrhythmias and sudden cardiac death. During her inpatient stay, her nortriptyline was reduced from a total daily dose of 225 mg to 75 mg while maintaining her other home medications. Three days later, she was admitted to her home hospital for observation due to her EKG still showing a Brugada pattern. Her nortriptyline levels were drawn which were found to be at a supratherapeutic level of 189 ng/mL while having been on 75 mg for the past three days which would presuppose that her levels were significantly higher while on a total daily dose of 225 mg. She was titrated off her nortriptyline with eventual normalization of her EKG. Conclusion: It is important not only to be cognizant of how to properly use pharmacogenetic data within established guidelines but also to be cognizant of the false sense of security and potential complications that can arise from use of such data. As pharmacogenetic testing trends towards ubiquity, systemic safeguards need to be put in place that minimize patient harm from the clinical use of pharmacogenetic data.

No. 48

Anxiety Preventing Weaning From Artificial Ventilation: Three Clinical Cases and a Proposed Protocol

Poster Presenter: Aaron Winkler
Co-Author: Michael Stephen Peroski, D.O.

SUMMARY:

Consultation-liaison psychiatrists are often consulted to assist with difficult weaning from artificial ventilation, which can be challenging and is often complicated by significant anxiety experienced during the process. This is often exacerbated by medical comorbidities which can include delirium, infection, poor sleep, the use of analgesic medications, pain, physical discomfort associated with presence of the endotracheal tube itself, and other medical conditions. Weaning from ventilation is a psychologically complex experience for patients, in that the perception that one cannot effectively oxygenate is both a symptom and cause of anxiety and fear. Consulting teams may not have expertise dealing with the affective component of this process. Their difficulty is further compounded by a paucity of literature on the topic. Of the available studies, some discuss the use of therapeutic techniques including CBT and meditation, while others point to the use of medications to assist in ventilator weaning, including antipsychotics, benzodiazepines, and dexmedetomidine. We will critically review the literature on this topic, present a series of three complex clinical cases of difficult weaning from mechanical ventilation complicated by anxiety, and will propose a symptom-focused protocol for ventilator weaning.

No. 49

Underrecognition of Catatonia in Psychiatric Patients After Recent Cerebrovascular Accidents

Poster Presenter: Abigail Yoonah Jo Hahn, M.D.
Co-Authors: Josie Pokorny, M.D., Stephen Hahn, M.D.

SUMMARY:

Mrs. C is a 59-year-old female with a history of major depressive disorder with psychotic features and recent left thalamic stroke. She was admitted to medicine for failure to thrive, stupor, and somnolence. Psychiatry was consulted for possible underlying uncontrolled depression driving these symptoms as medical evaluation was largely unremarkable. The patient's recent history included an admission to Neurology three weeks prior, where she was found to have a left thalamic stroke. Then she was briefly transferred to inpatient psychiatry for depression and suicidal thoughts. After discharge to home, she was noted by family members to have difficulty performing activities of daily living,

decreased oral intake, and progressive weakness which led to a subsequent admission. The medicine team narrowed the differential diagnosis to major depressive disorder, esophagitis and post stroke deficits. Evaluation was challenging as the patient was a poor historian with minimal engagement on interview. The patient's condition initially improved with fluids, but she continued to lack oral intake and suffered from physical debilitation which led to worsening acute renal injury, nasogastric tube insertion, and consideration of a percutaneous endoscopic gastrostomy tube. The patient's presentation was concerning for catatonia given her withdrawal, stupor, and mutism. On initial evaluation, her Bush-Francis Catatonia Rating Scale score was 12. Following a 30-minute lorazepam challenge, the patient demonstrated a profound change in affect with resolution of stupor and engagement in oral intake and spontaneous conversation. Patient also had an improved Bush-Francis Catatonia Rating Scale score of 0. In this poster, we discuss the challenges in recognizing catatonia and the importance of having a low threshold for the utility of lorazepam challenge in hospitalized patients with medical conditions and catatonia symptoms to prevent further unwarranted interventions and medical complications.

No. 50

Clozapine-Induced Eosinophilia: Severe Effects From an Often-Underutilized Lab Value

Poster Presenter: Adam M. Berns, M.D.

SUMMARY:

Introduction: Clozapine was approved by the FDA in 1990 for the treatment of schizophrenia and other psychotic disorders. It is famous for its use in treatment-resistant schizophrenia and has shown to be far superior to other antipsychotics in this regard. Clozapine is known to have many minor and major side effects, with agranulocytosis, myocarditis, pleural effusion, and paralytic ileus being among the most severe. However, there is less literature on clozapine induced eosinophilia. Many case reports have found that clozapine can cause eosinophilia, leading to some of the most life-threatening side effects, including those listed above. We present a case of clozapine induced eosinophilia and how it may result in a severe medical comorbidity. Case Report: The patient is a 69 year old man with a history of schizophrenia with command auditory hallucinations who presented medically with sepsis and hyponatremia, and was transferred to a psychiatric facility for agitated behavior. After an unsuccessful trial with olanzapine, the patient was started on clozapine, which was titrated to 100mg. The patient's symptoms began to slowly remit. Six weeks after the initiation of clozapine, the patient was admitted to medicine for fever and leukocytosis. The patient was found to have a pleural effusion with 96% eosinophils and required a chest tube. On his CBC, the patient was found to have an elevated eosinophil count of 1.09 (normal 0.0-0.5) with a 19.4% differential count (normal 0-6.0%). An extensive medical workup, coordinated among multiple medical departments, including workups for malignancy, Churg-Strauss syndrome, and parasites, was negative. The difficult decision was made to taper and discontinue clozapine to prevent further end organ damage. The patient's eosinophil count downtrended, which correlated with the tapering of clozapine. The patient was discharged back to the original psychiatric facility. He was started on ECT and risperidone with some improvement in symptoms. The patient was eventually discharged with no lab abnormalities. Discussion: This case presentation adds to the literature that clozapine induced eosinophilia is not simply a benign lab finding, but rather a marker that may be associated with other potential life threatening medical complications. We strongly urge that eosinophilia and other medical side effects be monitored when starting a patient on clozapine. Although clozapine may improve a patient's symptoms drastically, these benefits must be weighed against the increased risks associated with an elevated eosinophil count in conjunction with end organ damage. The severity of these complications warrant the development of a clear management protocol in order to help clinicians decide how to manage clozapine.

Catatonic Patient With May-Thurner Syndrome, Factor V Leiden Mutation That Develops Deep Venous Thrombosis: A Case Report

Poster Presenter: Darmant Bhullar, M.D.
Co-Authors: Felix Oscar Priamo Matos, M.D., Richard S. Arenson, M.D., Luisa S. Gonzalez, M.D.

SUMMARY:

Catatonia is the state of abnormal movements and behaviors which can occur due to both psychiatric and medical conditions. Literature review revealed that incidence of DVT (deep venous thrombosis) in catatonic patients is 25.3%, when compared to restrained patients without catatonia;(1) additionally, those with Factor V Leiden mutations have a baseline increased risk of DVT approximately 7 times that of non-carriers.(2) Therefore, these patients have a significantly higher risk of fatal pulmonary embolisms Catatonic state can lead to an increase in catecholamine and cortisol levels, which causes endothelial damage, thus propagating thrombus formation.(3) Adequate medical treatment can be challenging to enforce in decompensated psychiatric patients as their impaired mental state can lead to higher non-compliance rates. We present a case of a treatment noncompliant schizoaffective patient who was brought to the psychiatric emergency department due to disorganized behavior, developing sudden unresponsiveness and mutism. During her inpatient admission, patient developed left lower extremity pain and edema extending throughout the extremity. She was diagnosed with extensive DVT secondary to episodes of catatonic stupor. Further medical workup indicated that patient had May-Thurner Syndrome, heterozygous Factor V Leiden mutation, and Protein C deficiency. May-Thurner syndrome (MTS) occurs when the venous supply is compressed by the arterial system against bony structures in the iliocaval territory, the most common variant described as the compression of the left iliac vein between the overlying right common iliac artery and the fifth lumbar vertebrae. The extrinsic compression leads to venous outflow obstruction, subsequently causing venous hypertension, which overtime can lead to and present as DVT.(4) Thus far, a specific protocol for DVT prevention and treatment has not been established in psychiatry.(5) This case aims to outline possible pharmacological and behavioral management of DVTs in non-compliant psychiatric patients, especially during the inpatient hospitalization.

A Case of Persistent Altered Mental Status: Is It Mental Illness, Medication, or Malignancy?

Poster Presenter: Darya Terekhova
Co-Authors: Leonid Kapulsky, M.D., Janna S. Gordon-Elliott, M.D.

SUMMARY:

Altered mental status (AMS) is a common condition that has many treatable causes. In presence of a known psychiatric disorder, questions about a primary psychiatric process, medication effects, and sometimes stigma related to mental illness can complicate the diagnosis and management of AMS. We present a case of severe persistent AMS that illustrates this challenge. A 63-year-old man with bipolar disorder was admitted to the hospital with AMS that had developed over several weeks. Three months prior to the presentation he was hospitalized for a manic episode in the setting of lithium nonadherence, for which he was treated with reinitiation of lithium to high therapeutic levels (1.2-1.5 mEq/L), fluphenazine and valproate. His mania improved but following discharge he became acutely confused and was subsequently medically hospitalized, during which time he was taken off lithium and fluphenazine and his valproate dose was increased to 1 g bid. The patient's mental status deteriorated further and his family transferred him to our hospital. On presentation, the patient was restless, without any apparent awareness of his surroundings and nonverbal. The psychiatric consultation-liaison (C-L) team was called to assess for management of his bipolar disorder and a full medical workup was recommended. The evaluation revealed mild hypernatremia (149 mmol/L) and excluded common toxic, metabolic and infectious etiologies. Generalized parenchymal volume loss was seen on brain MRI and EEG revealed mild diffuse cerebral dysfunction and intermittent diffuse delta sharp waves. His CSF had normal parameters and was negative for testable infectious agents; a sample was sent for paraneoplastic antibody testing. With these nonspecific findings, focus remained on whether this presentation could represent an episode of the patient's bipolar illness. The C-L team followed to help manage his behavior. Valproate was adjusted to a therapeutic range (73.0 mg/L) and quetiapine was initiated at 25 mg qHS and increased to 25 mg at noon and 75 mg qHS. The diagnosis of

lithium neurotoxicity resulting from the combination of lithium and fluphenazine was considered (1, 2). However, it did not provide a specific prognosis since lithium neurotoxicity can be both reversible or irreversible with unclear predisposing factors (1, 2). During the third week, the paraneoplastic panel results returned positive for anti-voltage gated potassium channel antibodies, a malignancy workup was ordered and intravenous immunoglobulin therapy was started. The case illustrates the complexity of assessment and management of a patient with psychiatric illness who presents with persistently altered mental status. The evaluation may be skewed towards presuming the symptoms are due primarily to the mental illness or medications. With thoughtful collaboration between consulting teams, including the psychiatric service, a careful evaluation can be done, leading to appropriate treatment and good patient care.

"I Have Been Poisoned!": An Unusual Presentation of a Hematological Malignancy With Subsequent Complication by Steroid-Induced Psychosis

Poster Presenter: Diana V. Punko, M.D., M.S.
Co-Author: Meytal Fabrikant, M.D.

SUMMARY:

Ms. N, a 61-year-old female with history of schizoaffective disorder, presented to the ED with complaint of diffuse pain and suspicion that she had been poisoned. The patient reported a vague history and was unable to elaborate much further. In the ED, labs were significant for hemoglobin 7.0 g/dL and Coombs-positive autoimmune hemolytic anemia. Patient was admitted to medicine for management and diagnostic workup. Despite patient's insistence that she had been poisoned, toxicology workup was unremarkable. Literature review revealed limited evidence that her home medications – lithium, quetiapine, and bupropion – were implicated in her anemia, but nonetheless lithium was held due to concern about potential hematological effects. Per hematology, patient was started on prednisone and titrated to 60mg PO BID. On initial presentation, patient was found to be oddly-related with this apparent poisoning delusion but was otherwise calm, organized, and did not appear to be internally preoccupied. During the hospital course she became paranoid, pacing the hallways in the evening, at times talking to herself. Patient's hemoglobin responded well to medical management, and she was discharged on prednisone with hematology follow up. The discharge was coordinated with patient's Assertive Community Treatment (ACT) team, an intensive outpatient treatment service for individuals that have been diagnosed with a severe and persistent mental illness. Despite the close follow up and support of the ACT team, four days later patient was admitted to the psychiatry service as she complained of auditory hallucinations and demonstrated increasing paranoia and disorganization. These symptoms were attributed to steroid-induced psychosis/exacerbation of her underlying schizoaffective disorder in the setting of recent diagnosis of a serious and potentially life-threatening illness. Additionally, patient had been non-adherent to prednisone secondary to paranoia, and her hemoglobin reached a nadir of 4.8 g/dL. Patient was followed by hematology and ultimately diagnosed with small lymphocytic leukemia. Prednisone was tapered, and ibrutinib was started with good response. Patient returned to her psychiatric baseline and was discharged again to care of the ACT team. In this poster we discuss how this case illustrates a number of challenges faced by patients with both severe mental illness and co-morbid medical illness. We highlight patients who require treatment with medications that may exacerbate their underlying psychiatric disorder, who have paranoia about medications and resultant issues with adherence, and who risk decompensation triggered by the stress of being diagnosed with a serious medical illness. We propose mechanisms to mitigate these challenges through close collaboration between medical and psychiatry services, educating both the patient and family about the potential for medications to cause psychiatric side effects, and engaging the close support of the ACT team.

When Benzos Don't Work: The Role of ECT and Adjunctive Medications in the Treatment of Catatonia

Poster Presenter: Ehren I. Ekhause, M.D.
Co-Authors: Michelle Tuyet To, M.D., Naalla D.

Schreiber, M.D.

SUMMARY:

Mrs. T, a middle-aged eastern European woman with a past psychiatric history of schizoaffective disorder-bipolar type, tardive dyskinesia, and major neurocognitive disorder presented to the psychiatric consult service with malignant catatonia that had not improved on IV lorazepam administered at an outside medical hospital. The patient had originally been transferred from a psychiatric hospital to this outside hospital after she became catatonic during the treatment of a manic episode. A full neurological work up including EEG and MRI were unrevealing. Upon transfer to our hospital, the patient was mute, stuporous, bedbound, and rigid in all 4 extremities. She required a feeding tube. IV lorazepam was further titrated up with little effect on symptomatology. Memantine was prescribed, but the patient remained catatonic. ECT was initiated. After 5 rounds of ECT, Mrs. T was notably less rigid and was intermittently able to follow simple commands. However, she was, for the most part, unresponsive. Haloperidol was restarted to treat her psychotic illness, which we suspected was the most likely cause of her catatonia. Pt had thrice weekly ECT with progressively increasing dosages, and by the 10th round of ECT, she was more alert and could sit up in bed and make some purposeful movements. ECT was discontinued after 14 rounds when her improvement plateaued. Lorazepam was tapered off gradually due to concerns for oversedation. Following her final round of ECT, she began taking food by mouth but remained incontinent and bedbound. Her haloperidol was further titrated to manage suspected psychotic illness. She gradually regained her baseline functioning and was fully ambulating, toileting, and taking food by mouth about 3 weeks following the last round of ECT. Her haloperidol was discontinued during that time due to QTc prolongation and concern for EPS. Olanzapine was initiated and titrated up to manage continued psychotic and manic symptoms which became evident as the patient's functional status improved. In this poster, we plan to discuss the challenges of treating catatonia refractory to benzodiazepines. We will identify the various factors which negatively impact the treatment of catatonia. We will review the literature on catatonia to highlight alternative pharmacologic treatments. We hope to educate psychiatrists on the importance of aggressively treating refractory catatonia given its significant morbidity. We intend to present a treatment algorithm that lays out the role of sequential medication trials and parameters to maximize ECT response.

No. 55

Psychiatric Sequelae of Anti-DPPX Encephalitis: Case Report and Review of the Current Literature

Poster Presenter: Erin A. Dean, M.D.
Co-Authors: Swapnil Khurana, M.D., Christopher Sola

SUMMARY:

Psychiatrists are often asked to help manage patients experiencing psychiatric symptoms resulting from an underlying neurologic process. Dipeptidyl-peptidase-like protein-6 (DPPX) is a subunit of the voltage-gated A-type Kv4.2 potassium channel complex and is the channel responsible for transient, inhibitory currents in the central and peripheral nervous systems. Antibodies against DPPX can lead to encephalitis characterized by prodromal gastrointestinal symptoms, CNS hyperexcitability and cognitive deficits. More recent literature has highlighted psychiatric sequelae as well. We present a 54-year-old man evaluated for diarrhea leading to significant weight loss, followed by new-onset cognitive deficits. Extensive evaluation revealed DPPX antibodies in his CSF, and PET scan showed basal ganglia and cortical hypometabolism, suggestive of encephalitis. He was admitted, underwent plasmapheresis treatments for antibody removal, and was discharged home. Although psychiatry was not involved during admission, he was started on mirtazapine to assist with sleep, appetite and depressed mood. He initially did well after his plasmapheresis treatments, describing increased energy and denying lingering depression. However, his cognitive deficits continued to worsen. Two months after admission, family members noted new psychiatric symptoms including agitation and behavioral changes. He became increasingly confused and began expressing overt paranoia. His mood symptoms worsening, he reportedly composed a suicide note to his family. His neurologist stopped his mirtazapine, replacing it with low-dose quetiapine, which did not prove

beneficial. An even-tempered, non-violent man at baseline, he revealed a plan to kill his family. He was readmitted to a medical ward where psychiatry was consulted for management of his fluctuant mood, personality changes and delusions and erratic behaviors. On evaluation, he was calm and cooperative but was exhibiting delusional paranoia. His dose of quetiapine was increased to improve mood and psychotic symptoms. He underwent more plasmapheresis treatments followed by initiation of rituximab to manage his active B cell-mediated encephalitis. Throughout hospitalization, he demonstrated mood lability, poor sleep and impulsivity. Low dose divalproex was added for these symptoms. He was discharged on divalproex and quetiapine, with a plan to continue rituximab as an outpatient. Two months after hospitalization, he described improvement in his cognitive ability and gastrointestinal symptoms and resolution of his paranoia with cessation of odd behaviors. This case provides an opportunity to discuss anti-DPPX encephalitis, a condition rarely reported in current literature. We will review the pathophysiology of this illness and discuss illness progression, with an emphasis on potential psychiatric symptoms. We will also review the recommended treatments for neurological and psychiatric symptoms associated with this form of encephalitis.

No. 56

An Unusual Example of Neuropsychiatric Phenomena: Case Report and Literature Review

Poster Presenter: Kelli Marie Ruby, D.O.
Co-Authors: Walter Kilpatrick, Steven V. Fischel, M.D., Ph.D.

SUMMARY:

Purpose: The potential relationship between epilepsy and psychiatric symptoms has been evidenced in the scientific literature for the past 100 years, with potential behavioral disturbances described as occurring across the spectrum of ictal, postictal, and interictal periods. Specifically during the postictal period, aggression, panic, and psychosis are the most common neuropsychiatric symptoms seen. Manic symptoms are much less common, but do occur in a subset of epilepsy patients. This poster describes a case of new-onset partial complex seizures with postictal mania and reviews the literature regarding manic symptoms and epilepsy. We offer a case report which describes the clinical, electroencephalographic, and neuroimaging findings in a 59 year old man with history of CVA, who presented with new-onset complex partial seizure disorder complicated by postictal mania. This is a rare condition that is most commonly associated with complex partial seizures arising from a temporal focus. However, electroencephalography determined that our patient had primarily frontal epileptogenic foci. Treatment was complicated in this patient in terms of continued breakthrough seizures and behavioral management. Methods: We collaborated with the Baystate Medical Center Neurology Department and Electroencephalographic laboratory. We utilized Medline and Pubmed for literature review. Results: Our patient presented with postictal mania in the setting of new seizure disorder. His complex partial seizures were found to have multiple foci; however the most prominent focus was frontolateral in nature. This is an uncommon presentation of an already rare condition. Treatment was complicated, with some improvement being seen with control of seizures using valproic acid, phenytoin, and gabapentin. To manage behavior, olanzapine proved to be a better agent than risperidone for this patient. Conclusions: Consultation-liaison psychiatrists are often called to help manage behavior of patients in the hospital setting, especially when evaluation reveals presence of manic symptoms. However, seizures can produce symptoms similar to psychiatric conditions in the ictal, interictal, and postictal periods. Therefore, it is important to be able to identify postictal mania syndromes and apply this diagnosis to guide treatment decisions.

No. 57

Hepatotoxicity and Pancreatitis Secondary to Valproic Acid Treatment in a Patient With Manic Psychosis: A Case Report

Poster Presenter: Krishen Persaud
Co-Authors: Guitelle St.Victor, M.D., Michael Esang, MB.Ch.B., M.P.H., Fatemeh Parsian

SUMMARY:

A 20-year-old male admitted to medicine with a past psychiatric history of bipolar disorder, synthetic cannabinoid and phencyclidine use, presented with

abdominal pain, jaundice, and transaminitis. An abdominal ultrasound showed ill-defined patchy areas of hyperechogenicity in the posterior right hepatic lobe, favoring focal fatty infiltration. Psychiatry was consulted for psychosis and disorganized behavior. He was previously prescribed VPA titrated to 1500 mg daily for six weeks which was discontinued due to acute jaundice. The consultation team recommended lorazepam 3-6 mg and lithium carbonate 600 mg daily. He remained floridly psychotic and was admitted to inpatient psychiatry. He was started on paliperidone 3 mg, while lithium carbonate and lorazepam were further titrated. After 72 hours, he developed nausea, vomiting, and epigastric pain radiating to the back. Lab results showed serum lipase of 3648 and WBC of 16.21. This clinical picture raised a strong suspicion of acute pancreatitis. Patient was returned to medicine where he was treated with IV fluid hydration and nil per os diet. A week later he was medically cleared and readmitted to the psychiatry inpatient unit for further stabilization. Discussion: Valproic acid mediated hepatotoxicity is thought to be caused by inhibition of the mitochondrial ?-oxidation pathway leading to mitochondrial toxicity and microvesicular steatosis. The most common hepatic adverse reaction of VPA are mild elevations of aminotransferases.(3) The proposed mechanism of VPA-mediated pancreatitis involves the depletion of enzymes that act as free-radical scavengers.(2) This leads to accumulation of free oxygen radicals which damage cells by membrane lipid peroxidation, protein modification, and DNA damage, ultimately leading to tissue damage.(1) Literature review reveals that VPA-induced pancreatitis is not dependent on VPA serum level and commonly occurs within a year of commencement of therapy.(2) Conclusion: This case illustrates the need for physicians to educate patients treated with VPA about the side effects of pancreatitis and hepatotoxicity that may require prompt medical evaluation. We recommend close observation and diligent reporting of adverse effects.

No. 58

Off-Label Usage of Atezolizumab Inducing Encephalitis in Hepatocellular Carcinoma

Poster Presenter: Matthew Alexander Petrilli, M.D.
Co-Author: Philip R. Muskin, M.D., M.A.

SUMMARY:

Atezolizumab, a programmed death ligand 1 (PD-L1) inhibitor is currently FDA approved for the treatment of urothelial carcinoma and non-small cell lung cancer (NSCLC). It has been shown to have a variety of autoimmune side-effects. To date, there have been only 2 accounts of autoimmune encephalitis in the literature; a published case report and one mention in a phase 2 open label trial. This case is of a 70-year-old man with no formal past psychiatric history and a medical history notable for hepatitis C, complicated by hepatocellular carcinoma. He presented with frequent falls, worsening paranoia, thought disorganization and intricate visual hallucinations. Collateral from family revealed that the patient was cognitively intact and fully functional up until 12 weeks prior to the admission. He was enrolled in a phase 1 trial of atezolizumab for treatment of hepatocellular carcinoma. Brain imaging, along with lumbar puncture, paraneoplastic panel, and viral serology were all unremarkable. Laboratory work was notable for a cortisol level of 1.00 ug/dL and an ACTH level of 9 pg/mL with normal LH, FSH, prolactin and aldosterone. The patient was diagnosed with secondary adrenal insufficiency, a known side-effect of atezolizumab, started on IV steroids, and transitioned to oral steroids with dramatic resolution of his symptoms in an 8 day period. Although adrenal insufficiency can cause psychiatric manifestations, florid psychosis occurs less commonly and the quick resolution with steroids is more suggestive of autoimmune encephalitis. As immunotherapies are rapidly emerging as an option to treat malignancy, we can expect to see previously unknown side effects. Neuropsychiatric sequelae pose a significant complication to immunomodulating therapies such as atezolizumab and further case descriptions and research is required to advance the understanding of these medications.

No. 59

Caught in the Middle: Challenges in Transferring "Patients Not Wanted on Any Wards"

Poster Presenter: Michael Esang, MB.Ch.B., M.P.H.
Co-Authors: Guitelle St.Victor, M.D., Krishen Persaud

SUMMARY:

A small study published in 2008 by Christodoulou et al has revealed characteristics common to patients transferred to inpatient Psychiatry. These include living alone, belonging to a lower socioeconomic class, presenting with a disturbed and disruptive behavior, having a recent suicide attempt with persistent suicidal ideation, and the presence of a personality, neurodevelopmental, or neurocognitive disorder. We present two challenging cases that illustrate the above. The first is the case of Ms. A., a 64-year-old White female who had a past history of schizoaffective disorder, bipolar type, normal pressure hydrocephalus status post ventriculoperitoneal shunt placement, obstructive sleep apnea, obesity hypoventilation syndrome, and bronchial asthma, admitted to medicine after a mechanical fall at home. C-L Psychiatry was consulted for mania and psychosis. She was managed in the medical ICU for MRSA pneumonia with hypoxia. She was then transferred to medicine where she was medically cleared for admission to inpatient Psychiatry. She was not accepted by the inpatient Psychiatry team on account of the specialized care required for her medical comorbidities. After two weeks of intervention from the hospital's administration she was transferred. Within nine days, she became severely hypoxic and returned to medicine. On medicine she was stabilized, and with significant struggle, was re-admitted to inpatient psychiatry briefly, only to return to medicine for hypoxia where she expired. The second case involves a 28-year-old White male diagnosed with chronic schizophrenia and Cluster B personality disorder, who was admitted to the medical ICU following a suicide attempt via ingestion of a mixture of sodium hydroxide solution and liquid drain cleaner. He had also ingested about 50 pills of naproxen and ibuprofen. He developed fungemia from total parenteral nutrition, and required a jejunostomy for feeding. After successful medical treatment, he was medically cleared for transfer to inpatient Psychiatry. As he was uncooperative, a court order for Treatment Over Objection was obtained. Deemed too medically compromised by the inpatient Psychiatry team, intervention from the hospital's administration was necessary for his eventual transfer to inpatient Psychiatry. These cases illustrate the challenges faced by C-L Psychiatrists in transferring significantly compromised patients from non-psychiatric wards to inpatient Psychiatry. Although C-L Psychiatry traditionally operates at the intersection of Psychiatry and other medical specialties, the successful management of these patients taxed every discernible skill and expertise provided by the consulting psychiatrists. Both cases bring into sharp relief the complexity of situations where a psychiatric illness hinders adequate care of medical comorbidities and vice versa. In presenting these sophisticated cases, we hope to explore the difficulties in finding a balance between liaising and consulting.

No. 60

Investigations in the Early Aftermath of Trauma: An Analysis of Several Medications and Vital Sign Changes Implicated in the Development of PTSD

Poster Presenter: Stanley Lyndon, M.D.
Co-Authors: Samantha Chesney, Samantha Durbin, Joshua Hunt, Terri deRoon-Cassini

SUMMARY:
Background: Post-traumatic stress disorder (PTSD) has a lifetime prevalence of approximately 9% in the United States. 20-30% of patients admitted to trauma centers after an acute trauma meet criteria for PTSD in six months. (1) The point at which a traumatic event occurs represents the first opportunity to disrupt the acquisition and consolidation of the memory. Among the most robust are data suggesting that modulation of the endogenous opioid system may inhibit fear consolidation. (2) Medications such as morphine and propranolol, vital signs as well as loss of consciousness have been implicated in this modulation. (3) As these were discrete reports, a comprehensive analysis of all implicated factors in a single group of patients was attempted to rule out potential confounders. Methods: 158 patients who were admitted to the inpatient trauma service following an acute trauma were included. Exclusion criteria were age less than 18, GCS less than 13, and moderate-severe TBI. The patients completed PCL-5 at presentation, and CAPS-5 and PCL-5 at 1-month and 6-month follow-up. Data was collected from hospital records as well as ambulance field records. Variables collected included type of opioids, beta-blockers, benzodiazepines, and corticosteroids used,

their route of administration, time of administration and total dose. Heart rate, respiratory rate, blood pressure, and pain scores at various time points were also collected and analyzed. Results: Out of an N of 158, 114 were male, 44 were female. 80 were Caucasian, 62 were African-American, and 14 were Hispanic. Age ranged from 18 to 89, with an average of 41. 39 patients met CAPS-5 criteria for PTSD at 1 month post injury, and 30 met CAPS-5 criteria for PTSD at 6 months. Higher opioid use was related to lower arousal symptoms at both time-points (p=0.03). Benzodiazepine use was associated with higher avoidance and arousal symptoms at six-months (p=0.03). No significant associations were found with beta-blockers and corticosteroids. Lower systolic blood pressure in the field, ER, and discharge (p=0.04), lower initial heart rate (p=0.03), and higher pain scores at discharge (p=0.02) were all associated with PTSD at both time-points. Respiratory rate was not related to the development of PTSD at either time-point. Conclusion: While benzodiazepine use was associated with higher arousal and avoidance symptoms, opioid use was associated with lower arousal symptoms. Also, as higher discharge pain scores were associated with significant PTSD symptoms at both 1 month and 6 months after trauma, it may be prudent to treat posttraumatic pain adequately with opioids to lower PTSD symptom severity, although prospective studies have to be conducted to explicate the protective effect.

No. 61

Effectiveness and Tolerability of Aripiprazole in the Treatment of Delirium in Long QT Syndrome

Poster Presenter: Stanley Lyndon, M.D.
Co-Authors: Christopher Robert Takala, D.O., Rosa K. Kim, M.D.

SUMMARY:

Background: While there is growing literature on the use of aripiprazole in delirium(1) and the use of aripiprazole in children(2), there are no published studies evaluating aripiprazole as a treatment of delirium in children. We describe the treatment of hyperactive delirium with aripiprazole in an adolescent with congenital long QT syndrome and pre-B-cell acute lymphoblastic leukemia. Methods: 15-year-old with congenital long QT syndrome was admitted to the hospital after developing colonic perforation and E. coli sepsis following chemotherapy for a recent diagnosis of acute lymphoblastic leukemia. She underwent hemicolectomy with diverting ileostomy, and developed delirium following the procedure. Deliriogenic agents including benzodiazepines and opiates were minimized, and non-pharmacological methods to restore the patient's sense of time and familiarity were optimized. Initial pharmacological interventions included the use of melatonin and trazodone to help the patient reestablish her sleep-wake cycle. None of these interventions improved the patient's hyperactive delirium and repeated episodes of severe agitation. The use of dexmedetomidine was limited by the patient's bradycardic response, the use of valproic acid was limited by low platelets, and the risk of torsades precluded the use of the antipsychotics commonly used in the treatment of delirium. Aripiprazole was then started at a low dose of 2 mg daily after consultation with cardiologists. Given its relatively low propensity to cause QTc prolongation compared to the other antipsychotics, the potential benefits outweighed the risks. Results: The patient's sensorium and affect drastically improved over the next few days, and delirium resolved completely within a week, as assessed by CAM-ICU and NuDESC delirium rating scales. While QTc increased from 436 to 460 ms over the treatment duration, this was well within the safe limits for this patient, especially as multiple serial EKGs and telemetry did not show any evidence of arrhythmia. Aripiprazole was eventually discontinued safely with no relapse of delirium. Conclusion: Our patient tolerated aripiprazole well, experienced minimal adverse effects, and demonstrated improvement of delirium within a few days. Aripiprazole is an underutilized but useful medication in the treatment of agitation and confusion in children suffering from delirium, particularly in cases where risk factors preclude the use of other treatment options.

No. 62

The Value of Distress Screening and the Efficacy of Psychosocial Interventions in Psycho-Oncology: An Analysis of Observational Data

Poster Presenter: Stanley Lyndon, M.D.
Co-Authors: Sarah Elizabeth Slocum, M.D., Jennifer

Knight

SUMMARY:
Background: The diagnosis and treatment of cancer can lead to high levels of psychological distress and significantly impair quality of life.(1) Timely detection of these is essential for offering appropriate care and preventing comorbid psychopathology.(2) The National Comprehensive Cancer Network recommends using a single-item Distress Thermometer (DT) for screening. These scales have been extensively validated and have a cutoff score of >=4.(3) Evidence suggests that simply screening patients is not enough. Designing evidence-based psychosocial interventions and referral to appropriately trained professionals are recommended for further management. However, while specific psycho-oncology interventions are described in the literature, baseline distress characteristics of patients presenting to a psycho-oncology clinic, as well as the distress-reducing effect of standard clinic visits are under-described. Here we evaluate baseline distress levels of patients receiving psycho-oncology services at four cancer clinics and the change in distress scores after a 1-2 session psycho-oncology intervention. Methods: Patients completed DT at the beginning of their first and second visits and repeated the DT at the end of both visits. The visits comprised of a combination of pharmacotherapy and psychotherapy, and lasted up to an hour. Results: The analysis included 146 patients at first visit and 38 patients returning for a second visit. Age ranged from 19 to 79 years, with an average age of 47. 110 of the 146 were female, and 130 out of 146 were Caucasians. The average distress score was 5.71 at the beginning of first visit (PRE1), 3.86 at the end of first visit (POST1), 4.71 at the beginning of second visit (PRE2), and 2.82 at the end of second visit (POST2). Wilcoxon-Signed Rank Test was used to assess the paired difference between the visits. Difference between POST1 and PRE1 had a two-tailed Z value of -8.938 (p=0.000), significantly larger than the ±1.96 critical value required for a 95% confidence interval, suggesting a significant decrease in distress scores from a single hour-long intervention. There was a significant improvement in distress scores from PRE2 to POST2 (Z = -4.618, p=0.000). Distress scores were not significantly different between the end of the first visit and the beginning of the second (Z = 1.050, p=0.307), suggesting a persistence of the effect of the first intervention on the distress score. The average duration between the two visits was 17 days. Friedman test was done to substantiate the above findings (p=0.000). Conclusion: In adult cancer patients, a one-hour psycho-oncology intervention administered over one to two sessions significantly reduced patients' distress. This effect persists beyond the initial intervention. To our knowledge, this is the largest study to date describing distress among patients presenting to a psycho-oncology clinic and the impact of a psycho-oncology intervention to reduce distress scores.

No. 63

QTc Prolongation by Psychotropic Drugs and the Risk of Torsade De Pointes

Poster Presenter: Mousa Botros, M.D.
Co-Author: Krystal Leigh Nicht, M.D.

SUMMARY:
Clinical Case: This is a 48-year-old African American female with past psychiatric history of paranoid schizophrenia, anxiety and PTSD and past medical history of GERD, Migraine headaches, DMII, HLD, OSA, history of Pseudotumor cerebri who presented voluntarily to the emergency room due to anxiety. Patient referred to progressive course of debilitating paranoid thoughts fearing for her safety describing people are watching her and trying to hurt her. She intermittently eluded to poor appetite due to concerns the food is poisoned. She referred to unintentional recent weight loss of about 15 lbs over 2 months. Reported over 2 months before her presentation she has not been compliant with her home regimen Seroquel 300mg PO Daily and 600mg PO at bedtime. Upon examination, patient was not in acute physical distress. Patient's vital signs were essentially within normal limits. Laboratory investigations were suggestive of dehydration with elevated glucose levels (163mg/dl), elevated creatinine (1.8mg/dL) (n. 0.66-1.25 mg/dL) and urea nitrogen (37mg/dL) (n. 9-20 mg/dL), low estimated GFR (Glomerular Filtration Rate) (36mL/min/1.73m2). A picture of mild microcytic hypochromic anemia as well as mild leukocytosis (11.7wbc/hpf) was noted. Serum electrolytes revealed hypokalemia (3.4mEq/L). The urine

toxicology screen was presumed positive for benzodiazepines and cannabinoids. Patient received intravenous fluids in the medical emergency room. Patient was deemed medically cleared to be admitted to a psychiatry inpatient unit for stabilization. The patient received Seroquel 300mg PO one time at 14:49. Approximately one hour later, at the nursing station counter, the patient slowly slumped down towards the floor from a standing position with loss of consciousness. The patient remained unconscious for a short time. Vital signs showed BP 80/40 with HR 86. Finger Sticks Glucose were in the range of 96 – 134 mg/dL. Hospital Course: A code was called and the medical physician on duty evaluated the case to further investigate possible ACS vs arrhythmia vs hypovolemia. A 12-lead EKG was noted negative for ischemia but with prolonged QTc of 589msec. Patient was transferred to the CCU under telemetry. A 1:1 sitter was ordered for safety. Antihypertensive agents were discontinued. Intravenous fluids (3L of normal saline) were initiated. Repeat labs showed serum creatinine of 1.2mg/dL, low normal serum magnesium level of 1.7mEq/L (n. 1.7-2.2mg/dL) and a series of 3 negative serum troponins. An echocardiography was done showing an ejection fraction that was within normal limits with no significant valve abnormalities. After 48 hours, patient was stabilized. A series of repeat 12-lead EKGs were used to monitor the QTc, finally trending down to 460msec. Patient was followed up closely by the psychiatry consultation liaison service. She was prescribed Olanzapine 2.5mg PO at bedtime for psychosis. Patient was medically and psychiatrically stable and was discharged to self.

No. 64

Self-Induced Abscesses and Repeated Septicemia: Care at What Cost?

Poster Presenter: Tia Mansouri, M.D.

SUMMARY:

Self-induced infections are frequently thought to be a form of factitious disorder, associated with case reports in literature of patients creating a disease state by injecting themselves with contaminated substances to produce cutaneous infections, bacteremia, skin graft failures, and wound healing disorders. A case is reported of a 40-year-old female with a medical history of diabetes mellitus type 1, and a past psychiatric history of depression, anxiety, intravenous drug abuse, as well as chronic pain, who presents after a series of admissions for abscesses on her outer thighs requiring recurrent incision and drainage. Factitious disorder was suspected and psychiatric consultation evaluation was requested. She underwent incision and drainage of multiple bilateral abscesses of the thighs, while receiving broad-spectrum antibiotics and being monitored for septicemia and elevated blood glucose levels. The patient reported developing abscesses approximately once monthly and emphasized that she had not seen a psychiatrist in a “long time” because of a number of reasons such as insurance changes, multiple hospitalizations, and receiving refills of her medications (Paxil, Klonopin, Trazodone) from the hospital when she is discharged. She reported injecting herself at least 5 times a day with insulin, and only developing infections where she injects herself (flank, arm, etc), though she reported using clean equipment. However, when the patient was placed on continuous monitoring for self-harm behaviors, both on prior admissions and during recent encounters, she threatened to leave against medical advice, and in some instances, was successful in doing so. Prior evaluation notes that she was found to be self-injecting with contaminated materials, presenting a challenge for providers. In this poster presentation, the current criteria for factitious disorder and malingering in the Diagnostic and Statistical Manual of Mental Disorders 5th edition are reviewed, as motivating and incentive factors play a key role in distinguishing the two. The notion of how these relate to extreme poverty, chronic pain and opioid abuse, and under-treatment of psychiatric conditions will be explored. Other topics to be discussed will include capacity to refuse treatment and to leave against medical advice, as well as the challenges of creating a therapeutic alliance with such patients. Lastly, the poster will discuss suggestions for multi-disciplinary care coordination between providers in surgery, medicine, and psychiatry.

No. 65

The Evil Eye and Its Remedies: Reflections on Witchcraft, Hypnosis, and Psychosomatic Medicine

Poster Presenter: Viki Katsetos

SUMMARY:

The evil eye, the belief that looking upon someone with envy or jealousy can bring about bodily symptoms, stems from antiquity and is found in multiple cultures. Despite this ubiquity, the evil eye for many may conjure up images of the Old World, of ill-held superstitions long since negated by science. However, belief in the evil eye persists. The poster would elaborate on the history and traditions of the evil eye and its impact on modern day life and medicine. Areas of focus include the relationship between the evil eye and witchcraft fears in Europe. In particular, the poster would explore how "overlooking" was thought to be a way evil witches brought about physical harm to victims while the "spells" or remedies of good witches could undo this harm. With time, alternative scientific explanations and treatments were sought other than witchcraft to explain the bizarre physical symptoms predominantly women would experience. Coincidentally, these newer treatments, which included animal mesmerism and hypnosis, have parallels with evil eye remedies. The poster also aspires to describe how the concept of the evil eye continues to have an impact on the modern day health visit. Openness towards better understanding these beliefs not only allows for increased cultural awareness but can also provide information about the psychosocial stressors a patient is facing. After all, at its most basic core, the evil eye is a belief that interpersonal and intrapersonal strife can indeed manifest as somatic symptoms.

No. 66

Medical Incapacity Hold Policies Reduce Inappropriate Use of Involuntary Psychiatric Holds and Protect Patients From Harm

Poster Presenter: Michael Francis Zito, M.D.
Co-Author: Jonathan Pascal Heldt, M.D.

SUMMARY:

Background: Hospital inpatients with altered mental status often lack capacity to make healthcare decisions and are at risk of harm or death if they leave the hospital against medical advice. Despite this, most states do not have statutes for detaining patients who lack capacity as the result of a medical illness. Instead, the only available form of detainment in most jurisdictions is an involuntary psychiatric hold (IPH), also known as civil commitment, which is intended only for patients with a mental disorder as legally defined by the state. Nevertheless, clinical situations frequently arise in which detainment is necessary even in the absence of a clearly defined mental disorder, leading to inappropriate utilization of IPH statutes. Use of IPHs to detain patients lacking capacity may provide an unambiguous resolution to an acute crisis and mitigate the risk of patient harm. However, it also deprives the patient's civil liberties, risks provider liability for violation of mental health law, and obstructs appropriate disposition by implying the need for psychiatric treatment where it does not exist. Medical incapacity hold (MIH) policies, which permit the detainment of patients who lack capacity but do not meet criteria for an IPH, provide a potential solution. However, the effects of MIH policies have not been formally evaluated. Methods: A retrospective chart review was conducted on all adult medical/surgical inpatients placed on either an IPH or an MIH over the 1-year periods directly before and after implementation of an MIH policy at an academic medical center. The primary outcome was the frequency of IPH utilization in patients without evidence of a mental disorder as determined by two independent physician reviewers. A Cohen's kappa was calculated to determine the level of agreement between the two reviewers. Results: The Cohen's kappa score was 0.72 indicating substantial agreement between reviewers. Prior to MIH implementation, 17.6% (32/182) of all IPHs were placed on patients without a mental disorder. This decreased to 3.9% (6/152) following MIH implementation. A total of 70 MIHs were placed during the study period, with a mean duration of 4.3 days (range 0.0-17.7 days). Psychiatry and ethics were consulted in 78.6% and 18.6% of MIH cases, respectively. No instances of patient harm or litigation for malpractice, provider negligence, and/or false imprisonment were found in either study period. Conclusion: MIH policies represent a potential option for healthcare systems seeking to protect patients lacking capacity from harm while avoiding inappropriate use of IPH law. Further study of the effects of MIH policies in other healthcare systems is needed to validate these initial findings. Should the evidence continue to support the

appropriateness and efficacy of MIH policies, changes to relevant laws could be proposed to offer formal legal protection to providers attempting to act in the interests of their patients.

No. 67

The "e5150": Benefits of an Electronic Medical Record-Based Workflow for Initiating and Managing Involuntary Psychiatric Holds

Poster Presenter: Jonathan Pascal Heldt, M.D.

SUMMARY:

Background: Involuntary psychiatric holds (IPHs) are used across the United States to detain a patient considered to be a danger to self, a danger to others, and/or gravely disabled for the purpose of psychiatric hospitalization. The process of applying for an IPH varies between states but generally involves the submission of an affidavit (known as a "5150" in California) certifying the conditions of detainment. Even as many healthcare institutions transition to an electronic medical record, the process of submitting and managing the affidavit for an IPH often remains paper-based. This traditional workflow has several potential faults, including missing, incomplete, or illegible paperwork as well as staff and time inefficiencies. We report on our institution's experience after implementing an electronic version of an IPH known as the "electronic 5150" ("e5150"). Methods: Implementation of our institutional e5150 involved creating a visually similar electronic legal document, developing a new workflow in the electronic medical record (Epic Systems), obtaining approval from the Los Angeles County Department of Mental Health, and conducting staff education on writing and accessing the legal documents. A retrospective review was conducted on all e5150s written for patients presenting to the emergency department of an academic institution over a two-week period after implementation (6/5/17-6/19/17) and compared to all paper 5150s written over a two-week period prior to implementation (6/5/16-6/19/16). The primary endpoint was the time until availability (TUA) between IPH initiation (the start time of writing the legal document) and availability in the electronic medical record. Statistical analysis was conducted using a two-tailed Student's t-test in Microsoft Excel version 14.5. A secondary analysis was conducted using in vivo time analysis comparing psychiatry residents' workflow between e5150s and paper 5150s (study and analysis in process). Results: A total of 1771 e5150s were submitted over a one-year period following implementation of the e5150. Over the selected two-week study periods, the mean TUA for the e5150 was 1.9 hours (n=73, range 0.0-16.8) compared to 3.8 hours (n=49, range 0.2-19.7) for the paper 5150 ($p<0.01$). The results of the secondary in vivo analysis are still pending (estimated date of completion December 2017). Conclusion: Our results demonstrate that the creation of an electronic workflow for initiating an IPH results in significant time savings for provider workflow. End-user feedback on the e5150 system has also highlighted additional benefits to both healthcare providers and the institution, including enhanced legibility and reduced chances of error. Based upon our institution's experience, creation of an electronic workflow for IPH initiation improves provider and institutional workflow. Further study is warranted to directly assess the effects on patient care and to replicate these findings in other settings.

No. 68

Influence of the Major Coping Strategy on the Treatment Adherence and the Severity of Comorbid Conditions in Hemodialysis Patients

Poster Presenter: Hyunchan Hwang, M.D.
Co-Authors: Hyeri Kim, M.D., Doug Hyun Han, Sun Mi Kim, M.D., Ph.D., Jeong Ha Park, M.D., Ph.D., Ji Sun Hong, M.D., M.A.

SUMMARY:

Introduction Coping is defined as a cognitive behavioral effort to control stress made by various conflicts. Coping strategies are related to fitness and many studies have been published about the differences in the coping strategies of patients with cancer, multiple sclerosis, Parkinson's disease, etc. We aimed to investigate the influence of coping strategies on the treatment adherence and the severity of comorbid conditions in hemodialysis (HD) patients. Method Among 83 patients receiving HD at the artificial kidney room of the Chung-Ang University hospital, 51 HD patients were recruited. 2 were excluded because of Alzheimer's disease and 49 patients were enrolled. To measure treatment non-adherence, pre-dialysis serum phosphate levels

(SPL) and the 8-item Morisky medication adherence scale (MMAS-8), were collected. Age-adjusted Charlson's comorbidity index (CCI) was also calculated. Stress coping strategies were assessed using the Korean version of ways of coping questionnaire (K-WCQ) and divided the participants into 4 groups, problem-focused (PF) group, support-seeking (SS) group, hopeful-thinking (HT) group and emotion-focused (EF) group. Result The mean age of the 49 HD participants was 66 years, mean duration of chronic kidney disease (CKD) was 104.3±11.0 months, mean duration of HD was 73.3±9.8 months. 7 participants reported to mainly use PF coping strategy and 12 participants reported to mainly use SS coping strategy. Also, 30 participants reported HT as their main coping strategy. None reported mainly using EF coping strategy. There were no significant differences in age, sex, years of education, etiology of CKD, or duration of CKD among coping groups. Duration of HD was longer in SS group (117.0±99.1 months) than PF group (42.7±40.9) and HT group (64.6±53.5; F(2,46)=3.540, p=.037). Mean MMAS-8 score was higher in PF group (7.2±0.5) than HT group (5.2±2.0; F(2,46)=4.045, p=.024). Mean age-adjusted CCI score was lower in PF group (5.0±1.8) than HT group (7.2±2.1; F(2,46)=4.440, p=.017). There were no significant differences in the number of participants with non-adherence defined by SPL>5.5mmol/l. Discussion CKD requires a lot of social resources when compared to other chronic diseases. SS coping strategy is defined as asking for the support of others to cope with stress. As the HD period lengthens, each participant is thought to change their personal main coping strategy to SS strategy to cope with the need for social resources made by the disease. PF strategy is an active coping strategy that overcomes stress by confronting the problem itself, as opposed to the HT strategy, a passive coping strategy that overcomes stress by keeping distance between the problems and wishing a different situation. Due to the differences between these stress coping strategies, the PF group is thought to more actively participate in treatment than the HT group, and therefore has better treatment adherence and less severe comorbidities.

No. 69

Serious Game for Patients With Obsessive-Compulsive Disorder

Poster Presenter: Doug Hyun Han
Co-Authors: Hyunchan Hwang, M.D., Hyeri Kim, M.D., Sun Mi Kim, M.D., Ph.D., Jeong Ha Park, M.D., Ph.D., Ji Sun Hong, M.D., M.A.

SUMMARY:
Introduction The exposure and response prevention (ERP) is thought to be one of first-line treatments independently or combined with other treatment options for obsessive compulsive disorder (OCD). We hypothesized that serious game, Hit the chicken would improve the clinical symptoms in patients with OCD. In addition, the symptom improvement in patients with OCD would be associated with increased functional connectivity between dorsal anterior cingulate cortex (dACC) and dorsolateral prefrontal cortex (DLPFC) as well as decreased functional connectivity between dACC and basal ganglia in response to game play. Methods Fifteen patients with OCD and age and sex matched healthy control subjects were recruited. At baseline and 3 week follow up, all patients with OCD were asked to complete questionnaires of demographic data, Yale-Brown Obsessive Compulsive Scale (Y-BOCS), Beck Depressive Inventory, and Beck Anxiety Inventory. In addition, all patients were asked to be scanned for assessing functional connectivity of brain using resting state functional magnetic resonance imaging (rs-fMRI) at baseline and 3 week follow up. Patient with OCD were asked to play Hit the chicken at least 30minutes/day and five days/week for 3 weeks. Results At baseline, OCD group showed increased left dACC seed connectivity with right cingulate gyrus, compared to healthy comparison subjects (p[uncorrect]<0.001) as well as increased right dACC seed connectivity with right cingulate gyrus and left superior occipital gyrus (p[uncorrect]<0.001). In addition, OCD group showed decreased right dACC seed connectivity with left superior frontal gyrus (p[uncorrect]<0.001). During 3 week game play, brain connectivity from left dACC seed to right frontal precentral gyrus as well as right dACC seed to left inferior frontal gyrus and right middle frontal gyrus have been increased in OCD group (p[uncorrect]<0.001). In a comparison of changes in brain connectivity during 3 week game play, OCD patients with symptoms improvement showed increased brain connectivity from left dACC seed to right superior frontal gyrus, compared to OCD

patients without symptom improvement (p[uncorrect]<0.001). In addition, OCD patients with symptoms improvement showed decreased brain connectivity from right dACC seed to left lentiform nucleus, compared to OCD patients without symptom improvement (p[uncorrect]<0.001). Controlling BDI and BAI scores, the mean ? values of the right superior frontal gyrus were negatively correlated with the changes of Y-BOCS scores in OCD patients (r=-0.76, p<0.01). Discussion To the best knowledge, current research is first study to assess the clinical symptom and brain change in response to serious game in patients with OCD. Current results suggested that serious game for OCD could improve clinical symptoms including OCD, depressive and anxiety symptoms as well as brain connectivity from dACC to DLPFC and basal ganglia.

Haloperidol-Induced Priapism

Poster Presenter: Sumana Goddu, M.D., M.P.H.
Co-Authors: Deepa Anand, Caesa Nagpal, M.D.

SUMMARY:

Background: Priapism can be a side effect of several psychotropic medications. While Trazodone is well known for it, priapism has been described with several typical & atypical antipsychotics, antidepressants, antihypertensives, alcohol and drug use, anticoagulants and rarely with anxiolytics. Various drugs have been implicated in low flow ischemic priapism characterized by abnormalities in the veno-occlusive mechanism. Whereas, high flow priapism typically occurs after trauma to the genitals. Impotence can be a complication due to resulting ischemia. We report a case of a 28 year old male who developed priapism following intramuscular injection of haloperidol. Method (Case Report): Mr. R was a 28 year old Hispanic Male with past psychiatric h/o Bipolar disorder who presented with depression and suicidal ideation with plan by suicide by cop, with concurrent use of Marijuana & Kush. At the psychiatric ER, patient received Seroquel, Depakote & Ativan, before being transferred to the inpatient psychiatric hospital (Harris County Psychiatric Center). He was seen during the night and started on Abilify 15 mg qam & Depakote 500 mg qam & 1000 qhs due to good response during prior admission. Early morning next day, patient got very agitated displaying threatening behavior towards staff. He was emergently medicated with IM Haldol 5 mg + Ativan 2 mg + Benadryl 50 mg at 07:45. He had not yet received any scheduled medications. At 15:42 house officer paged as patient had developed non-ischemic priapism since last 8 hours. Patient was immediately sent out to the ER and received treatment (aspiration of the corpora cavernosa + phenylephrine) Discussion: Priapism can occur soon after starting patients on atypical antipsychotic medication, or in patients who have been on stable doses of psychotropic medication for long periods of time, or after a change in dose or with the addition of another medication, or as idiosyncratic reaction that is not dependent on dose or duration (Sood et al., 2008). Drug-induced priapism results from alpha-adrenergic blockade combined with anticholinergic activity. Alpha-adrenergic agonists (phenylephrine, epinephrine and ephedrine) are used to treat priapism. Andersohn et al found an association between the drug affinities for the alpha-1 receptor of different antipsychotics and their relative propensities for causing priapism. Cloazpine has the highest affinity for alpha-1 adrenergic blockade, followed by Quetiapine, Haloperidol and Loxapine (Compton and Miller, 2001). There have been several case reports of priapism caused by Clozapine, Olanzapine, Risperiodne, Abilify and Ziprasidone Conclusion: Priapism can be a idiosyncratic side effect of typical or atypical antipsychotics. Proposed mechanism is alpha-1 adrenergic blockade.

No. 71

Role of Health Information Technology (HIT) in the Treatment of Mental Illness

Poster Presenter: Sumana Goddu, M.D., M.P.H.

SUMMARY:

Background: Health Information Technology (HIT) has promising applications in Mental Health. The applications range from Electronic Health Records, psychiatry-specific Computerized Provider Order Entry, Clinical Decision Support Systems, therapeutic interventions etc. Therapeutic interventions can be delivered via electronic platforms such as Telepsychiatry, email, instant messaging, internet, blogs, forums, social networks, podcast, computer

games, virtual reality etc. e-Health is an umbrella term encompassing all of the above. Cognitive Behavioral Therapy (CBT) is amenable to be disseminated via technological media. Web-based CBT has an advantage that it is cheaper and less time/labor-intensive than traditional face-to-face CBT. HIT can also bring about primary care and mental health integration. Dr. Thomas Insel proposes some solutions to leverage HIT to advance mental health. For example Big Data analytics in psychiatry, preemptive diagnosis of depression or psychosis by collecting biomarkers like speech patterns, exploring autism biomarkers, and delivery of psychosocial therapeutic interventions via smart phones. In this study, we review the various therapeutic interventions that hold promise for mental health disorders. Method (Literature Review): We searched PubMed using search terms like Health Information Technology (OR) Health Informatics (AND) Mental Health (OR) Psychiatry (AND) treatment (OR) therapy. Our search yielded a total of 96 articles. Of them 50 were retained based on titles. We went through the 50 abstracts and finally retained 18 articles for literature review. A general search yielded 2 additional articles. Discussion: Many of the studies we found were done outside of USA. Several modes of psychotherapies (eg. CBT) can be effectively delivered via electronic platforms such as internet-based, mobile-based and social-media based interventions. The spectrum of mental illness that could benefit from such CBT are depression, anxiety, eating disorders, chronic pain etc. Mobile health (m-Health) platforms are another very useful media with several advantages. VR is another technology that has applications in areas such as PTSD, forensic psychiatry etc. Another huge benefit of HIT based interventions is that they can be disseminated in large scale, at a cheaper price, and can improve accessibility to hard-to-reach populations such as homosexuals, remote areas etc. Telepsychiatry improves access to remote areas and ensures compliance, regularity and continuity of care. Computer Games specifically designed as mental health interventions are successful in cases such as adolescents with behavioral issues and elderly with cognitive issues. Conclusion: Promising HIT solutions (e-health) for mental health include web-based CBT, mobile Health, VR, computer games etc. Till now we have only sought biological and behavioral solutions for mental health disorders. It is time to look at technology as a solution as well.

No. 72

Evaluation of Schizophrenia Patients' Delusional Contents in Associations Between Gender Differences and Life Events

Poster Presenter: Meltem Tasdemir Erinç
Co-Authors: Pinar Cetinay Aydin, Güliz Özgen

SUMMARY:
Background: Gender differences and life events in schizophrenia are one of the most consistently reported issues of the disease. Moreover research suggests that the contents of delusions in schizophrenia are influenced by culture and social environment. Objectives: Examination of a link between content of delusions and gender differences, life events in patients with schizophrenia and detail the background of delusional contents that existing in our society based on our sample group. Methods: A hundred patients diagnosed with schizophrenia according to Diagnostic and Statistical Manual of Mental Disorders (DSM-IV-TR) criteria were included in this study. The content of delusions were compared following the classification system developed by Huber and Gross. Additionally assessment performed via socio-demographic and clinical data collection form, life events scale (B form), brief psychiatric rating scale (BPRS), positive and negative syndrome scale (PANSS). Results: We observed that patients presenting delusions with persecutory content were the most frequent type followed by delusion of reference, delusion of grandiose and delusion of religious respectively. 'Physical/mental injury' was the most frequent persecution and the frequencies of persecutors were family, non-specific person and neighbors respectively. The male patient group had significantly higher number of events correlated with crime and forensic cases than female patient group meanwhile female patient group had higher number of events correlated with family-health. The number of life events, distress and adaptation scores were higher in patients that presenting delusions with reference content. Similarly we reported a significant positive relation between thought broadcasting and distress score mean furthermore negative relation between

religious delusions and distress score mean. Limitations: We have examined limited number of samples with the lack of control group while assessing the life events and we did not use the diagnosis scale. Conclusions: Cultural and socio-demographic factors seem to have a marked influence on the content of delusions in schizophrenia. Correlations between life events and content of delusions provide a valuable clue about defense function and psychodynamics of delusions to cope with stress.

No. 73

Charles-Bonnet Syndrome Complicated by Alcohol Withdrawal in the Setting of Delerium Tremens

Poster Presenter: Milin Balsara

SUMMARY:

Mr D. S. is a 41 yo African American male with a history of alcohol use of about "a gallon of vodka a day" who presented to the emergency room because he was ready to quit drinking "cold turkey." D.S. had, over the past several years, been visiting an ophthalmology specialist at a top US hospital in another state where he had previously resided and been diagnosed with retinitis pigmentosa. He had a central visual field sparing, however his peripheral vision was markedly compromised to the point of being rendered legally blind and was walking with a cane. The visual deterioration occurred within the last decade and only been recently been diagnosed by a top specialist. Mr S. reluctantly admitted that he had been experiencing visual hallucinations, and was admitted to the medical-psychiatric integrative care unit from the emergency room. He reluctantly admitted that over the course of his visual deterioration, he had been seeing snakes. Normally, these snakes were "disgusting" however they had a surreal appearance to them that, upon further investigation, was almost cartoonish in nature. Mr. S. presented to the Med-Psych unit in great distress. He was sweeping and swatting at his legs and chest. The once garish snakes were now not only more real, but tactile. He could feel the snakes crawling on his legs. Mr S. began to aggressively pace the hallways with his cane. He went from nurse to nurse begging for a broom, and habitually stomped his feet and swatted at his legs. In the setting of alcohol withdrawal his baseline hallucinations had taken on a hyper-realistic presentation. It appears that, in the past, Mr S. had never explicated upon these serpentine hallucinations as they were not distressing to him. It was at this time that the treatment team began to investigate the history behind these symptoms and placed a working diagnosis of Charles Bonnet Syndrome. The curious presentation which prompted the patient's seeking help only occurred in the setting of acute alcohol withdrawal in which the visual symptoms became exacerbated, with emergence of tactile hallucinations representing two distinct etiological phenomena namely CB and DT. The patient left AMA and relapsed into habitual alcohol use, however the diagnosis was similarly confirmed in subsequent visits. The patient is still actively seeking ETOH treatment, and continues to attempt, unsuccessfully, to enter into and stay in chemical dependency treatment. The presentation of hallucination exacerbation in the setting of withdrawal continues, and remains a barrier to the patient's continued success in sobriety, and remains refractory to treatment.

No. 74

Longstanding Somatization as a Suspected Prodrome for Late-Onset Schizophrenia

Poster Presenter: Sandy Chan

Co-Authors: Ivan Chik, Barbara Wilson, M.D.

SUMMARY:

Mrs. A, a 58 year old Asian woman with prior medical training and no past psychiatric history presented to the emergency room with persecutory delusions, ideas of reference, paranoia and multiple vague somatic complaints. A review of her past records revealed she had seen several outpatient providers over the last 8 years for ambiguous somatic symptoms which gradually increased in frequency and were similar in theme to her physical complaints when she ultimately presented to the emergency room in acute psychosis. Her visits with multiple providers were complicated by her prior medical training which may have added feasibility and credibility for her symptoms throughout the years. Although some providers had suspected an underlying psychiatric illness, she was never officially diagnosed with a psychiatric disorder or started on neuroleptics since her symptoms had not affected

her personal life. At the ED visit, she believed government spies were trying to poison her through radiation and also thought people she met online were trying to attack her. She attributed these paranoid thoughts as the reason why she was experiencing muscle aches, abdominal pain and frequent headaches. The patient had no history of psychotic symptoms, substance abuse, family history of mental illness, or past psychiatric hospitalizations and was relatively active in her day-to-day activities until her presentation. She was admitted to the psychiatric unit and initial work-up including tests for HIV, TSH, B12, syphilis, drug screen, and head imaging were non-contributory. Given her workup continued to be negative, a primary psychiatric disorder was considered. A differential including schizophrenia, delusional disorder, and dementia was considered. Her presentation was atypical given her age, lack of negative symptoms, and relatively high level of functioning prior to admission. After psychiatric admission, she was stabilized on olanzapine and discharged with outpatient follow-up. The goal of this poster is to provide insight into how late-onset schizophrenia may differ clinically compared to a younger age group – especially among high functioning patients such as this one. We will also highlight key points in ruling out more common causes of psychosis in late adulthood.

No. 75

Celecoxib as Adjunctive Therapy for Schizophrenia in Setting of Elevated C-Reactive Protein

Poster Presenter: Sarah A. Hamilton, M.D.
Co-Author: Hossam Guirgis, M.D.

SUMMARY:

Mr. Z. is a 30-year-old Caucasian male with no known medical history and a past psychiatric history of schizophrenia, stimulant use disorder, cannabis use disorder, and alcohol use disorder. He has a history of lengthy inpatient psychiatric hospitalizations in context of repeated medication noncompliance, substance abuse, and violation of his conditional release from a not guilty by reason of insanity verdict. Previous medication trials have involved dual antipsychotic use with long-acting injectable formulations, mood stabilizing agents, and two incomplete trials of clozapine. Most recently, he was admitted involuntarily for inpatient psychiatric hospitalization due to decompensation as evidenced by severe psychosis, disorganized speech, and bizarre behavior. He was treated with olanzapine and lithium, but due to an overall lack of treatment response, a re-trial of clozapine was considered. A baseline C-reactive protein (CRP) level was collected and found to be elevated without clear symptoms of infection to the best of our knowledge. Due to hypothesized contributory effects of inflammatory markers in the psychopathology of mental illness, celecoxib, a selective COX-2 inhibitor, was started while treatment with olanzapine and lithium continued. With this medication regimen, treatment team observed marked improvement in psychosis, disorganization, and degree of insight. CRP was decreased from 65.40 mg/L to 6.70 mg/L. PANSS score, initially 129 with prominent symptoms in all three scales, was decreased to 10. While caution is advised when attempting to draw direct conclusions from this treatment approach, it is certainly worthwhile to consider alternative adjunctive therapies in treatment-refractory populations due to the debilitating implications of this disorder. This poster will review emerging literature on the role of inflammation in schizophrenia, and discuss the potential of anti-inflammatory augmentation strategies.

No. 76

Patterns of Violence and Aggression at Presentation in Patients With First-Episode Psychosis: Is There a Change Over Time?

Poster Presenter: Sarah Keane, M.D.
Co-Authors: Attila Szigeti, Felicity Fanning, Mary Clarke

SUMMARY:

Background: Research suggests that the prevalence of violent behaviour in the first episode of psychosis (FEP) is greater than during the later stages of the illness. Objectives: To assess the prevalence and clinical correlates of aggression and violence in individuals presenting with FEP to an early intervention psychosis service. To evaluate whether this prevalence has increased in recent years when compared to a similar previous study. Methods: Retrospective cross-sectional study of clinical case notes and database records using a keyword search of a sample of patients with FEP aged between 18

and 65 years presenting from a geographically defined catchment area to a secondary referral psychiatric service over a 4-year period (2010-2013 inclusive). Use of the Modified Overt Aggression Scale to retrospectively assess aggression and violence recorded as occurring in the week prior to, and the week following each patient's presentation with FEP. Results: The overall proportion of individuals in our first episode sample found to be aggressive and violent was similar to the study fifteen years previous. However, a higher percentage of our sample (22%) was violent in the week prior to presentation compared to the prior study (13%). Aggression was independently associated with involuntary admission status (OR=11.31 CI 4.09-31.32) and high activation (OR=4.48 CI 1.81-11.1). Violence was associated with involuntary status and high activation both in the week prior to, and the week following presentation (OR=9.11 CI 3.47-23.86, OR=12.54 CI 2.37-66.41)(OR=2.75 CI 1.06-7.13, OR=25.71, CI 2.93-225.13). Conclusions: Aggression and violence rates in FEP appear relatively stable over time. Keywords: Violence, Aggression, Schizophrenia, First episode psychosis.

No. 77

Development of Schizophrenia in a Patient With Juvenile-Onset OCD

Poster Presenter: Shabber Agha Abbas
Lead Author: Sheema Imran, M.D.
Co-Authors: Avi Siwatch, Asghar Hossain, M.D.

SUMMARY:

Introduction: In a subset of obsessive-compulsive disorder (OCD) patients, schizophrenia co-occurs with the OCD commonly predating the onset of schizophrenia. The implications of comorbid OCD and schizophrenia on long-term treatment management and prognosis are substantial. Objective: The objective of this case report is to report a case of comorbid juvenile-onset OCD and schizophrenia in a 20-year-old patient. Methods: A retrospective chart review was used to study behavioral and cognitive manifestations of a single patient with juvenile-onset OCD with subsequent development of schizophrenia. ? Case: The patient was a 20-year-old Asian male carrying multiple past psychiatric diagnoses including impulse control disorder (ICD), oppositional defiant disorder (ODD), and OCD who was single, unemployed, and living with his mother. Police brought him to Bergen Regional Medical Center for psychiatric evaluation in response to complaints of agitated, aggressive, destructive, and psychotic behavior. He had a history of multiple inpatient psychiatric admissions and a high rate of readmission. The mother reported he caused destruction of property at home, was pacing about the house, was impossible to redirect, and was demonstrating religiously preoccupied behavior. Due to his psychotic behavior and demonstrable threat posed to others he was admitted involuntarily to our short-term care facility unit. No specific trigger was identified for his latest behavior. He denied suicidal and homicidal ideation; denied auditory or visual hallucinations; and denied use of any controlled substances. The patient had been noncompliant with his prior prescribed treatment regimens and this had been well documented during prior hospitalizations. Family history was positive for non-specific anxiety disorder on the side of his biological father. Social history indicated a socially withdrawn individual having poor school grades who was raised by a single mother. Mental status exam was congruent with the clinical presentation. He was superficially cooperative upon interview but guarded and evasive at times. He was diagnosed with schizophrenia, paranoid type, continuous, with history of OCD, ODD, and ICD. In the emergency department he was prescribed risperidone 1 mg QAM, risperidone 2 mg QHS, and risperidone long-acting injectable. During hospitalization we added divalproex sodium 1000 mg QD. He was discharged following stabilization. Discussion and Conclusions: The diagnosis and management of juvenile-onset OCD cases that develop schizophrenia offer unique challenges. Clinicians must be cognizant of the need to treat both conditions aggressively as patient compliance and presence of psychosis may exacerbate treatment success. We suggest that evidence-based guidelines should be developed to provide therapeutic options including combination of pharmacologic and behavioral therapies that solicit family participation and provide adequate symptom resolution.

No. 78

An Atypical Antipsychotic and Benzodiazepine Used to Treat Haloperidol Induced Catatonia: A Case

Study

Poster Presenter: Stephen L. Mecham, D.O.

SUMMARY:

Introduction: Catatonia, a syndrome characterized by abnormal movements, behaviors, and withdrawal, is a condition that is most often seen in mood disorders, but can be also seen in psychotic, medical, neurologic, and other disorders. Most episodes of catatonia can be classified as excited, retarded, or malignant. Symptoms can vary, and recognition and treatment of catatonia can play an important part in both psychiatric and medical treatment as it inhibits treatment, confuses diagnoses, and be potentially fatal if untreated. This case presents a patient who initially presented psychotic, became catatonic after treatment with neuroleptics, with recovery using an atypical neuroleptic and benzodiazepines. Case: ST is a 43 year old male with schizophrenia who presented to the hospital with worsening psychosis and aggression toward his caregivers, his parents. On the medical floor patient was disorganized and agitated with floridly psychotic behavior. Patient had been off of his psychiatric medications, lithium and clozapine. He was restarted on his lithium dose and clozapine was restarted at an initial dose due to being off of it for greater than 3 days. Haloperidol 5 MG IV TID was added for psychosis and agitation. The day after treatment was initiated, patient showed some improvement in agitation and was less psychotic, though there was concern for catatonia. A 2 mg IV ativan challenge was given and the patient became sedated, this was thought to be a failed challenge. That night patient became unresponsive. Psychiatric medications were held for 1 day and patient worsened with waxy flexibility, mutism, posturability, and mitgehen. A 2 mg IV ativan challenge was given and patient responded after 10 minutes. Patient continued to receive ativan and was transferred to inpatient psychiatry. As the dose was increased patient became more interactive, but he was disorganized and aggressive. This was thought to be due to underlying psychosis so olanzapine added at 5 mg BID. While this improved his aggression, it worsened his catatonia. Eventually patient was on 6 mg of ativan TID and 10 mg of olanzapine BID that he began to take consistently orally. He had significant improvement on this dose consistently. He was almost discharged on this dose but had recurrence of his psychotic symptoms. His HS dose of olanzapine was increased to 15 mg. On a week of this dosing patient took pills PO, eat food, perform hygiene tasks, and interactivity with interviewers improved. Discussion: The onset of catatonia in response to haloperidol, the difficulty in treating a patient who is both catatonic and psychotic, and the eventual treatment used draw attention to this case. ECT may have been an option for this patient, possibly with earlier resolution of symptoms, however guardian did not consent for the procedure. A pharmalogic course for treatment remained as an available option, and resolution of catatonia and psychosis with an atypical neuroleptic and benzodiazepines.

No. 79

Factors Contributing to Subjectively Reported Side Effects of Clozapine in Treatment-Resistant Schizophrenia

Poster Presenter: Su Mi Park

Lead Author: Yong Sik Kim

Co-Authors: Hee Yeon Jung, Tak Youn, In Won Chung

SUMMARY:

Background and Aims Clozapine (CZP) has been considered the most effective medication in treatment-resistant schizophrenia, yet reported to produce adverse effects. Subjective experiences of antipsychotic drugs are significantly associated with a number of clinical variables, making it difficult to pin down the direct effects. However, only a few studies focused on subjective side-effects related to CZP treatment. This study aimed to clarify the factors that contribute to subjective side-effects of CZP, including the association between CZP plasma concentrations and subjective side-effects in patients with schizophrenia. Methods Sixty-four schizophrenia patients (DSM-IV) treated with CZP (mean duration; 5.8±4.8 years) were included. The Korean version of Liverpool University Neuroleptic Side Effects Scale (LUNSERS) for patient-reported side-effects and Positive and Negative Syndrome Scale (PANSS) for clinician assessed psychopathology were applied. We investigated the relationship between PANSS factor scores and LUNSERS side-effects —the total score (total-s) for the subjective neuroleptic effects and the red herring score (RH-s)

for items unrelated to neuroleptic effects— using correlation and multiple regression analyses, as well as Haye's mediation model. Results According to multiple regression model, among duration of CZP, the RH-s of LUNSERS, the positive symptom (P-S) of PANSS and the anxiety/depression symptom (A/D-S) of PANSS, only the RH-s of LUNSERS and the A/D-S of PANSS appeared to be significant factors predicting the total-s of LUNSERS. We tested Hayes' mediation and moderated-mediation models to see how psychopathological symptoms, CZP treatment and the degree of over-reporting bias influence the total-s of LUNSERS. Firstly, the P-S of PANSS in the model was put as independent variable and the total-s of LUNSERS as an output variable. A series of mediators was put into model as following order: CZP dose, plasma level of CZP, the A/D-S of PANSS, the RH-s of LUNSERS. As a result, a direct effect of the P-S on LUNSERS did not reach a significant level. Only the indirect effect of the P-S via the RH-s of LUNSERS was found to be significant. Secondly, we tested the model for the effect of the A/D of PANSS on the total-s of LUNSERS using moderated-mediation model. The RH-s of LUSERS was put into the model as a mediator and duration of CZP as moderated-mediator in the way of the A/D-S of PANSS to the RH-s of LUNSERS. As a result, the effect of the A/D-S on the RH upon duration of CZP was significant. But the indirect effect of the A/D-S on the total-s of LUNSERS via the moderated RH-s of LUNSERS was not significant. Rather, the A/D-S has direct effects on the total-s of LUNSERS. Conclusion The A/D-S and over-generalized reporting tendency were found to be key factors associated with subjective side-effects of CZP, independently of the actual CZP concentration level in patients with schizophrenia.

Atypical Bridging of Oral Risperidone to Once Monthly Paliperidone Injection in Adolescent With Schizophrenia: A Case Report

Poster Presenter: Suchitra Joshi

SUMMARY:

R.J. is a 15 year old bi-lingual male, who presented to the psychiatric emergency department after running around the streets naked. The patient has a past psychiatric history of schizophrenia with three hospital inpatient admissions this year. Upon admission, RJ was disorganized, paranoid, responding to internal stimuli, tangentially praying in Spanish, and had limited insight. The patient rated a score of six on the clinical global impression severity (CGI-S) on admission. During his previous admissions, potential medical and substance induced causes of psychosis were ruled out. His home medication regimen consisted of risperidone 4mg per day, but severe noncompliance was reported by the patient and parent. He was previously on olanzapine 10mg which was discontinued due to excessive weight gain. Upon this admission, the patient spent seven days on the unit where his risperidone was restarted and optimized to 6mg per day with diphenhydramine 50mg daily. Due to the patient's medication non-compliance issue and failure of two antipsychotics, the team discussed the possibility of initiating the patient on a long-acting antipsychotic. Currently, there are no FDA approved long-acting antipsychotics for the treatment of schizophrenia below 18 years of age. Pope and colleagues reported six case reports of successful transition of adolescents 14 to 17 years old to paliperidone palmitate once monthly (PP1M), however there is limited guidance on bridging and tapering off oral antipsychotic when transitioning to a long-acting in the adolescent population. In collaboration with the outpatient pharmacy, a prior authorization was initiated for PP1M 234mg and 156mg to assess for medication coverage and ensure continuity of care at discharge. At discharge, the patient had markedly improved symptomatology with CGI-S of two and he was able to assist in coordinating his follow-up outpatient care. As an outpatient, RJ received the first dose of PP1M 234mg on day one and oral medications were tapered to risperidone 2mg with diphenhydramine 50mg at bedtime. The second dose of PP1M 156 mg was given on day twelve and oral taper continued with risperidone 1mg and diphenhydramine 50mg daily. The patient returned on day nineteen for follow-up, at which risperidone and diphenhydramine were discontinued. The patient reported mild sedation and no incidence of extrapyramidal symptoms. This case was a successful bridging to PP1M with oral risperidone in an adolescent patient with schizophrenia. The patient continues to do well one month after treatment. He

denies any symptoms of psychosis, and has tolerated the medication with minimal side effects.

No. 81

Dup and Prognosis in Paranoid Schizophrenia

Poster Presenter: Maria teresa Gonzalez-Salvador
Co-Authors: Rosario Gutierrez-Labrador, Pilar Rojano

SUMMARY:

Objective: The aim of the present study is to analyze the relationship between DUP (duration of untreated psychosis) and prognosis in paranoid schizophrenia Methods: It is an analytical observational cross-sectional study. The sample was composed of 52 patients with DSM IV diagnosis of paranoid schizophrenia who were attended at two Outpatient Mental Health Centers of the Community of Madrid. Data collection was conducted through an interview, during whicha sociodemographic questionnaire was applied to the patient, DUP was registered and outcome was measured using the Strauss and Carpenter Prognostic Scale. Lastly, a quantitative statistical analysis was performed between DUP and prognosis. Results: We found no significant differences regarding prognosis between the groups divided into short and long DUP (t=0,97; p=0,369>0,05). Since no criteria has been established to classify DUP into short and long, and in consonance with the latest studies, we established new cut-off to divide DUP: DUP 12 months, without finding any significant differences ((p=0,518>0,05). The correlation between DUP and prognosis was found to be negative (r=-0,173) but non-significant (p=0,254>0,05), being therefore unable to prove any association between them. Conclusion: Our study did not find any association between DUP and prognosis in paranoid schizophrenia.

No. 82

Cannabis Use, Functionality, and Prognosis in Paranoid Schizophrenia

Poster Presenter: Maria teresa Gonzalez-Salvador
Co-Authors: Pilar Rojano, Rosario Gutierrez-Labrador

SUMMARY:

Background: It is unclear if research findings support clinical opinion that cannabis use leads to worse functionality and prognosis in people with paranoid schizophrenia. Our purpose is to test the hypothesis that any regular consume of cannabis before or after the onset of schizophrenia, might deteriorate the functionality and the prognosis in a short-medium amount of time in this illness. Objectives: This study has as a principal objective to analyze the influence of cannabis consume in the functionality and prognosis in a short-medium amount of time in a group of patients with paranoid schizophrenia. As a secondary objetive it has proposed to describe the sociodemografic and clinics variables of the sample. Material and methods: : It is an analytical observational cross-sectional study. A sample of 52 patients with DSM- IVTR diagnosis of paranoid schizophrenia was obtained from consecutively attended at two Outpatient Mental Health Centers of the Community of Madrid. Data collection was conducted through an interview, in which it was applied to the patient a sociodemographic and clinical questionnaires, the PSP scale (Personal Scale and Social Functioning) and Strauss and Carpenter prognostic scale, used in order to measure the Outlook. Lastly, a quantitative and qualitative analysis of the collected statistical variables was performed. Results: patients who did not use cannabis after the first episode of psychosis had PSP scale scores significantly higher (p = 0.042). There was no relationship statistically significant between cannabis use and prognosis. Conclusion: Implementing measures focused on reducing cannabis use and promote early detection systems to avoid cannabis use after the first episode of psychosis could be useful measures to achieve functional recovery in paranoid schizophrenia. Limitations: The main limitation of the study was the relatively small sample size.

Insight as Predictor of Functionality in Paranoid Schizophrenia

Poster Presenter: Maria teresa Gonzalez-Salvador
Co-Authors: Pilar Rojano, Rosario Gutierrez-Labrador

SUMMARY:

Insight in schizophrenia patients could be a factor influencing functionality. OBJECTIVES: 1.- To evaluate the functionality of the paranoid schizophrenia in a sample of 52 patients, subsequently treated at three Mental Health Centres from Madrid (Spain).2.- To evaluate insight as a

secondary variable that might intervene as a relevant factor in relation with the functionality of the illness. Material and methods: A cross-sectional design was employed, using validated scales, PSP, to evaluate functionality, SUMD, to evaluate insight, and a clinical and sociodemographic questionnaire. METHOD: Inclusion criteria were: age 18 to 65 years; paranoid schizophrenia DSMIV diagnostic criteria; two to ten years of illness evolution. Exclusion criteria were: to be incapacitated; any impediment that could interfere in the execution of the study. Written informed consent was a necessary requirement to participate. Results: No significant statistical relation between insight and functionality is shown. Conclusion: In order to evaluate the potential of the therapeutic work related to the insight role in the functionality of schizophrenia patients, the sample used should be extended.

Paliperidone Palmitate Every Three Months (PP3M) Treatment Compliance and Satisfaction Compared With PP1M in People With Severe Schizophrenia

Poster Presenter: Juan J. Fernandez-Miranda
Co-Author: Sylvia Díaz

SUMMARY:

Background Paliperidone palmitate every three months (PP3M) requires injections only 4 times a year and this is expected to facilitate patient's treatment compliance and satisfaction. This study compares PP3M treatment compliance and satisfaction with PP1M in patients with severe schizophrenia previously stabilized with PP1M for at least 2 years. The effectiveness and tolerability were also measured. Methods 12-month prospective, observational, open-label study of patients with severe schizophrenia (GCI-S>=5 at the beginning of PP1M treatment) treated with PP3M after at least 2 years of stabilization with PP1M (N=42). Treatment satisfaction with PP3M vs PP1M was assessed with the Treatment Satisfaction Questionnaire for Medication (TSQM) and with a visual analogue scale (VAS, 0-10). Effectiveness was measured with number of hospitalization admissions due to psychiatric decompensation and CGI-S. Tolerability assessments included extrapyramidal symptoms, laboratory tests (haematology, biochemistry and prolactin levels), weight, adverse effects reported and injection-site pain or reaction every three months. Other psychiatric medications and also reasons for treatment discontinuation were recorded. Results CGI-S at baseline was 3.9 (0.5), with no significantly changes after 12 months. No patients discontinued PP3M treatment or were referred to hospital psychiatric ward due to decompensation. There were neither significant changes in weight or prolactin levels nor biological parameters alterations, and lower incidence of sedation and orthostatic hypotension was reported. There was an increase in TSQM (from 'satisfied' to 'very satisfied'; $p<0.05$) and VAS (from 7.7(0.9) to 8.6 (0.7); $p<0.01$) between 1M and 3M PP treatment. Reasons reported for higher satisfaction were less injections/year, less sedation and lower feeling of being medicated/ill. No differences were found related to doses (Range: 350-1050 mg/3M). Conclusions Apart from similar effectiveness and somewhat better tolerability, patients with severe schizophrenia lengthy treated with PP1M showed more satisfaction with PP3M. This formulation allows patients not only to improve treatment adherence but also to feel more satisfied with it.

High Doses of Second-Generation Long-Acting Antipsychotics in the Treatment of Patients With Severe Resistant Schizophrenia: A 24-Month Follow-Up

Poster Presenter: Juan J. Fernandez-Miranda
Co-Author: Sylvia Díaz

SUMMARY:

Background People with severe schizophrenia treatment compliance is important to reach clinical and rehabilitation goals; and antipsychotics good tolerability at any doses is required for that. The aim of this study is to evaluate treatment retention, effectiveness and tolerability of high doses of second-generation antipsychotic long-acting injectable (LAI) formulations in the treatment of patients with severe (CGI-S of 5 and over) resistant schizophrenia. Methods 24-Mont prospective, observational study of patients with resistant schizophrenia who underwent treatment with 75 mg and over of risperidone long-acting injectable (RLAI) (N=60), 175 mg and over of monthly paliperidone palmitate (PP)(N=30) and 600 mg and over of

aripiprazole once-monthly (AM)(N=10). All of them were previously treated with at least two different antipsychotics with poor outcomes. Assessment included the Clinical Global Impression-Severity (CGI-S), the WHO Disability Assessment Schedule (WHO-DAS) and the Camberwell Assessment of Need (CAN) at the beginning and after three, 12 and 24 months. And also laboratory tests (haematology, biochemistry and prolactin levels), weight , adverse effects reported, other psychopharmacological treatments and reasons for treatment discontinuation. Hospital admissions in the previous two years and during the follow-up were recorded. Results The average doses were: RLAI= 111.2 (9.1) mg/14 days; PP = 228.7 (11.9) mg-eq/28 days; and AM =720 (110) mg/28 days. For all LAIs tolerability was good, decreasing side effects reported and biological parameters alterations compared with previous treatments, in special in AM group. There were no discharges due to side effects with AM, one with PP and three with RLAI.; and three with RLAI and one with PP due to lack of effectiveness. Weight and prolactin levels decrease, but not significantly except for AM. After two years, CGI-S ($p<0.01$), CAN ($p<0.01$) and WHO-DAS in the four areas (self-care $p<0.005$; occupational $p<0.01$; family $p<0.01$; social impairment $p<0.05$) decreased with all injectables. Moreover, there were significantly less hospital admissions than during the previous 24 months: 1.3(1.1) vs. 0.3(0.2) ($p<0.001$), with no differences among injectables. And less antiparkinsonian treatments ($p<0.01$ for PP and AM). Retention in treatment after 24 months was 90% with RLAI, 93,3% with PP and 100% with AM. Conclusions Tolerability of high doses of second generation long acting antipsychotics (RLAI, and in especial for PP and AM) was very good, being useful in improving treatment adherence in patients with severe resistant schizophrenia, and helping this way to get clinical stabilization and better functioning. Low discontinuation rates also support good patient acceptance of an injectable antipsychotic formulation. These patients were clozapine candidates in routine clinical practice, so high doses of second generation LAIs could be a more comfortable and tolerable

No. 86

D-Cycloserine: A Novel Antidepressant to Be Explored?

Poster Presenter: Navjot Kaur Brainch, M.B.B.S.
Co-Author: Sanya Virani, M.D., M.P.H.

SUMMARY:

Navjot Brainch, MBBS; Sanya Virani, MBBS, MPH Background: The shortcomings of existing antidepressants used in patients with treatment resistant depression have evoked much interest in exploring alternate novel yet cost-effective drugs that target N-Methyl D-Aspartate receptors (NMDARs). In addition to ketamine, evidence for the effectiveness of the antituberculosis drug, D-cycloserine (DCS) in this realm has also been steadily accumulating. Observations with DCS have been overlooked in the past in favor of monoamine oxidase inhibitors. DCS acts as a partial agonist at the NMDAR-associated glycine site at low doses and as an antagonist at higher doses. In this review, we present the limited but convincing evidence to suggest the promising antidepressant properties of DCS when administered independently at high dose or as an adjuvant in controlled settings has promising antidepressant properties. Methods: Systematic searches of PubMed, Cochrane, Medline and other sources were conducted to identify trials focusing on the antidepressant effects of DCS. Searches were also conducted for relevant background material regarding its pharmacological function. Results: Results from four double-blinded trials and two open-label studies comprising a total of 84 subjects that had received DCS to date are summarized. Findings from a large double-blinded trial (22 patients) and an open label-pilot study (5 patients), which administered 250mg/day (1) and 100mg of DCS prior to Transcranial Direct Magnetic Stimulation (2) respectively did not reveal statistically significant improvement in the Hamilton Depression Rating Scale (HAMD) and Montgomery-Åsberg Depression Rating Scale (MADRS) scores. A follow-up study (26 patients) to the above trial, administered high doses of DCS (3), gradually titrated to a maximum of 1000mg/day, and showed a significant reduction in depressive symptoms and HAMD and Beck Depression Inventory (BDI) scores in the majority. Another open-label trial that administered intravenous ketamine followed by 8 weeks of adjunctive therapy with pyridoxine and DCS at 1,000 mg/day showed a 60% remission rate in

7 subjects. (4) Additional randomized, doubled-blind, placebo-controlled trials on patients with Obsessive Compulsive Disorder reported that those with comorbid depression showed an improvement in symptoms in favor of DCS post-treatment. (5, 6) Conclusion: All the above studies reported that DCS was safe and well-tolerated and four of them showed a reduction in depressive symptoms without psychomimetic and dissociative effects. In sum, DCS is a cost-effective novel therapy whose antidepressant properties need larger trials to add to the cumulative evidence on its efficacy as an independent drug or an adjuvant. Through this review, we will attempt to tabulate the details of study design, patient population, methods and results of the above-mentioned studies and make recommendations for exploring avenues for research in this area.

No. 87

Is the Concept of Pseudo Neurotic Schizophrenia Still Valid? Case Series

Poster Presenter: Navjot Kaur Brainch, M.B.B.S.
Co-Authors: Yassir Osama Mahgoub, M.D., Penchaya Atiwannapat, M.D., Sanya Virani, M.D., M.P.H.

SUMMARY:

Introduction: Pseudo neurotic schizophrenia was the term coined by Paul Hoch and Philip Polatin in 1940 to describe a subgroup of schizophrenic patient who presented with (disorders of: thinking and association; emotional regulation; sensorimotor and autonomic function) and secondary symptoms (pan-anxiety; pan neurosis; pan sexuality). The term became obsolete in 1980's, after addition of term Borderline Personality disorder in DSM III. Despite the fact that this term is no longer in use, some data argues about its existence and the response to antipsychotic. We present 2 recent cases that matches the diagnosis of pseudo neurotic schizophrenia. Objectives: To increase the awareness of a subgroup of schizophrenic patient who can mistakenly diagnosed with depression, anxiety or personality disorder and highlight the need for careful assessment to overcome challenges in diagnosis and treatment due to symptoms overlap. Methods: PubMed and Google Scholar search using the keywords, "pseudo neurotic schizophrenia" in addition to a summary to 2 recent cases. Case 1: 29-year-old male with history of major depressive disorder, generalized anxiety disorder, borderline personality disorder, and history of multiple suicidal attempts, presented with vague anxiety, and suicidal ideation. He was oddly related, occasionally disconnected with noticeable thought block. He exhibited ambivalence in making decisions and reported confusion about his sexual orientation and preference. History suggested a decline in functioning over the last 11 years. Historically, he was diagnosed with borderline personality disorder with poor response to several antidepressants. He was managed with Quetiapine 300 mg with improvement of anxiety, depression, and suicidal ideation, thought process and socialization skills. Case 2: 39-year old female with previous history of depression and anxiety with no previous hospitalizations, was admitted management of reported paranoia, auditory and visual hallucinations. She appeared anxious and perplexed, her speech was tangential with circumlocution. She provided vague stories related to her life that suggested poor boundaries with strangers, inability to maintain relationship with family of friend's and difficulties keeping jobs. She vaguely reported having suicidal ideation. Personality disorder was initially suspected. Collaterals from family suggested that she was suspicious, paranoid, and odd with poor interpersonal and social functioning. A diagnosis of schizophrenia was formulated and she responded to risperidone 6 mg with improvement in her symptoms. Conclusion: Some schizophrenic patient can present with pan anxiety symptoms that tend to overlap with depression, anxiety disorders and borderline personality. Careful and detailed assessment is key for appropriate diagnosis and treatment as patient might respond favorably to antipsychotics and poorly to antidepressants.

No. 88

Attitude and Preference Toward Treatments of Depression Among General Public in Non-Western Country

Poster Presenter: Ahmad N. Alhadi, M.D.
Co-Authors: Abdulrahman Alkaff, Abdullah Aljumaiah, Faisal Aljabrain, Mohammed Alsubaie, Abdulrahman Alarfaj

SUMMARY:

Background Patients' treatment preference has received a growing interest in the last decade. American Psychiatric Association (APA) has considered the involvement of patients' preference in decision-making as an important part of clinical practice. Objective We aim to assess the preference and attitude toward different types of depression management in Saudi Arabia. Method The study is quantitative observational cross–sectional with a convenient sample who included people who were 18 years old or above in Saudi Arabia and not seeking treatment for depression. The participants read a detailed description of one of the five treatments for depression randomly: (psychotherapy, antidepressants, guided self-help, bibliotherapy, or Internet-based self-help) then were asked to read brief descriptions of all five treatments. Result The total number who completed the questionnaire was 2342 participants. Psychotherapy was the most preferred treatment option 49.2% (N=1154) followed by guided self-help, 16% (N=374). In contrast, antidepressant, and Internet-based self-help were found to be the least preferred types of treatment. These results are similar to a study was done in United Kingdom. Also, females preferred psychotherapy and self-help modalities where males preferred medications. Other socioeconomic factors will be discussed. Conclusion In the future, we recommend conducting a randomized clinical trial study to assess the effect of choosing the preferred type of treatment among the five types of depressant treatments on the depression outcome and why people preferred psychotherapy rather than other types of treatment.

No. 89

Obese Patients With Mood Symptoms Show Greater Food Addiction but Lower BMI: A Mexican Sample of Patients From an Obesity and Weight Control Clinic

Poster Presenter: Alfredo Bernardo Cuellar-Barboza
Co-Authors: Sarai González, Antonio J. Lopez, Dionicio Galarza

SUMMARY:
Background: The association between mood disorders and obesity has been widely examined. Clinical phenomena such as food addiction (FA) may be a link between obesity and mood disorders, as current research suggests. Here we aimed to assess the prevalence of mood disorders and FA in obese and overweight patients; to compare the clinical presentation of patients with mood disorder symptoms (MDS) vs. patients with no mood disorder symptomatology (NMDS). Methods: Participants of a weight loosing program (June to October 2015) from an Obesity and Weight Control Clinic of a University Hospital in Monterrey, Mexico; were assessed using the Patient Health Questionnaire (PHQ-9), the Yale Food Addiction Scale (YFAS), and the Generalized Anxiety Disorder Assessment (GAD-7). Those with positive PHQ-9 scores were further consulted to establish a diagnosis of depression or bipolar disorder using the Mini-international Neuropsychiatric Interview (MINI). Other clinical and demographic variables were assessed in an interview by a senior clinician. Results: 89 patients were included in this study (MDS= 43, NMDS= 45), most of them were female (66.3%), with a mean age of 41.5 (SD = 13.04) and mean BMI of 36.3 (7.5 SD). 48.3% of patients had at least symptoms of mild depression and 41.6% of patients had at least mild symptoms of anxiety; of these, 18% had a major depression diagnosis, 4.5% a bipolar disorder diagnosis and 3.3% had suicide risk by MINI. 34.8% rated positive for FA. MDS patients were significantly more females than the NMDS group (67.4% vs. 65.2%, p=0.049), had significantly lower BMI (34.1 SD 6.3 vs. 38.4 SD 8, p=0.005%). They also showed significantly more food addiction rates (94.7% vs. 5.3%, p=0.000), regular tobacco (94.1% vs. 5.9% p=0.001) and alcohol use (76.2% vs. 23.8% p=0.047). Conclusions: The prevalence of FA, MDS and depression found in this sample is similar to that reported in the literature. However, we found an intriguing lower BMI but higher FA rate in MDS patients vs. NMDs. Limited by sample size, clinical measurements and transversal design, this study contributes to the definition of finer obesity phenotypes related -as biological studies suggest- to lower self control, abnormal reward sensitivity and negative affects, thus exhibiting FA and MDS. Moreover, it helps to distinguish specific treatments for patients suffering from different forms of obesity.

No. 90

Wellness Initiatives in Psychiatry Residency Training: A Four-Program Perspective

Poster Presenter: Pallavi Joshi, D.O., M.A.
Co-Authors: Robert Rymowicz, D.O., Karen Thuy Duong, D.O., Katherine Alexis Jong, M.D.

SUMMARY:
Residency represents a challenging stage of medical training, and concern for the wellbeing of residents and fellows has received significant attention in recent years following a series of widely publicized tragedies. Resident physicians are at high risk for depression and burnout and physicians have an elevated risk of suicide. The National Wellness Institute defines wellness as an active process through which people become aware of, and make choices toward, a more successful existence. Recognizing that wellness is critical to the success of physicians in training, the ACGME and GME committees are implementing personal wellness programs during residency. Generally, such programs combine active and passive initiatives targeting physical, mental, social, and intellectual wellness. To ensure the greatest effect in reducing burnout, training programs and institutions should create wellness programs that intervene at both the individual and organizational levels. While psychiatry residencies have mobilized efforts to implement wellness programs, there is great diversity in their approaches.The authors provide an overview of wellness initiatives in 4 distinct residency programs in 4 states. The goal of this collaborative review is to identify approaches to wellness based on specific training program characteristics and to promote the exchange of ideas regarding wellness initiatives. Northwell Health - Staten Island University Hospital (Staten Island, NY) offers yearly residents' retreat, biweekly class specific support groups, regular interdepartmental social activities, and psychiatric assessment and treatment for residents from all departments. Psychiatry residents participate in SMART-R training and run Balint groups. Online resources include free wellness education modules and questionnaires. Rutgers New Jersey Medical School - (Newark, NJ) offers regular didactics on wellness, spring and winter retreats, and weekly sessions chaired by the resident wellness committee. Available to all residents are catered watercolor and yoga sessions, monthly interdepartmental social activities, free access to state of the art athletic facilities, and free unlimited counseling, substance use treatment, and pharmacotherapy. University of Washington (Seattle, WA) has a resident wellness committee to organize events, including a yearly retreat and weekly business lunch meetings for residents from all classes. The program also offers discounted cost psychotherapy with community providers, and a residency-year specific weekly "T-group". University of Texas Southwestern Medical Center (Dallas, TX) has a resident wellness coordinator and launched a wellness app to easily schedule medical and dental appointments and childcare. The program offers discounted cost psychotherapy for residents, weekly outdoor activities, and residents therapy group. A task force is developing an effective process to help residents and their team debrief after a bad patient outcomes

Development of Premenstrual Dysphoric Disorder (PMDD) in a Patient With Unreported History of Sexual Assault

Poster Presenter: Lauren Rae Iandoli, M.D.
Co-Authors: Zohaib Majid, Shabber Agha Abbas, Asghar Hossain, M.D.

SUMMARY:
Introduction: Adverse effects of sexually traumatic experiences on psychological, physical, and social well-being are not fully recognized and understood yet. There have been many studies that suggest an association between sexual violence and Premenstrual Dysphoric Disorder (PMDD). Our case report emphasizes the need to probe patients presenting with PMDD for any past history of sexual assault, which may alter treatment regimen decisions. Objective: The objective of this article is to report a case of PMDD that was triggered by a prior sexual assault and unreported by the patient until recently, despite numerous psychiatric hospitalizations for major depressive episodes. Case: This is a 28-year-old Indian female, with a history of multiple psychiatric hospitalizations for Major Depressive Disorder with Psychotic Features, who was brought to Bergen Regional Medical Center by EMS accompanied by her mother for evaluation of worsening anxiety and depressive symptoms in the

context of medication noncompliance. After the patient's previous discharge, she returned to her baseline functional status. However, beginning one month ago, the patient began decompensating and was reportedly feeling increasingly withdrawn, selectively nonverbal, sleeping less, and missing activities of daily living. Two days prior to presentation, she reported onset of her monthly menses that made her nervous, agitated, and restless to the point that she demanded medication to calm herself. According to the mother, the patient's symptoms, specifically her anxiety, menstrual cramping, and dysphoria coinciding with the onset of menses, were reminiscent of symptoms she had endorsed following a traumatic rape by an ex-boyfriend; that assault caused an unwanted pregnancy that had to be terminated. The patient denied any history of post-traumatic stress disorder (PTSD) symptoms or substance abuse. While in the hospital, she was started on Aripiprazole 10 mg PO QD and Paroxetine 10 mg PO QHS. The patient was stabilized and discharged home. Discussion: Review of literature indicates that an unreported history of sexual abuse may be prevalent in some patients presenting with PMDD. In our patient, this indeed was the case. Although the possible etiologies of PMDD are mostly medical, no formal screening mechanism has been devised as of yet to elicit relevant past trauma in patients presenting with new-onset PMDD. Currently, Sertraline, Fluoxetine, and Escitalopram are the first-line treatment choices for PMDD; however, there may be a role of anti-depressive anti-psychotics, such as Aripiprazole, as well as other serotonergic drugs, in select patients presenting with related psychiatric symptomotology. Conclusion: We have observed that eliciting past sexual abuse histories is crucial for the management of PMDD. In our observation, continuing previous psychiatric medications, in patients with new-onset PMDD symptoms, may be beneficial in the context of their comorbid psychiatric symptoms.

Poverty as a Cause and Consequence of Mental Health

Poster Presenter: Lawrence Takungo
Lead Author: Rosemarie Caskey, M.D.

SUMMARY:

A 48 years old Caucasian male with a past psychiatric history of recurrent, severe, Major Depressive Disorder was admitted to a state psychiatric facility for suicidal ideation with a plan to blow off his head with a gun. According to the patient, he lives with his mother and is unable to pay his huge financial debts or for his child support. Patient previously was the Director of Operations for a reputed company but, he spent his money carelessly, went into financial crisis, started drinking alcohol, and was terminated from his job six months ago because of his excessive drinking. Financial difficulties could lead to Depression, Generalized Anxiety Disorder (GAD), Substance Abuse, and Hypertension (HTN). Patients who have mental illness could experience financial distress as a result of their condition. In such situations, it might be beneficial if patients could get financial management counseling as counselors could detect patients at the edge of their financial breakdown and refer them to a psychiatrist. This case study addresses the impact caused by personal unsecured debt, job loss or retirement, and financial loss during the recession on mental health.

No. 94

The Invisible Risk of Psychotropic Medications

Poster Presenter: Sureshkumar H. Bhatt, M.D.

SUMMARY:

Understanding the relevance of the QTc interval on the Electrocardiogram (EKG) is an essential part of good psychiatric practice. The Rotterdam Study found that prolongation of the heart-rate corrected QT (QTc) interval increased the risk of sudden cardiac death (SCD) in adult patients by 60%, independent of other known risk factors (Straus et al). QTc prolongation is usually asymptomatic, so treating physicians must be vigilant to monitor EKGs of patients treated with drugs known to cause QTc prolongation. Since many psychotropic medications prolong the QTc, psychiatrists must carefully monitor the EKGs of patients before and during drug therapy. This study examined the EKGs of 107 patients in order to determine the baseline QTc. The EKGs of 107 patients were analyzed, aged 17 to 67 years, chosen at random from our clinic population. 85.04% of the patients were male, and 14.95% were female. EKGs that were reviewed had been performed during non-psychiatry related visits. No

patients were on psychotropic medications when the EKG test was conducted. The QTc interval differs somewhat in men and women. 85.04% of the patients were male, and 14.95% were female. 50.54% of the male patients (n = 46) had a normal QTc interval (less than 430 ms), 50% of the female patients (n = 8) had a normal QTc (less than 450 ms). 18.68% of the male patients (n = 17) had a borderline QTc (431-450 ms), while 37.5% of females had a borderline QTc prolongation (451-470 ms). 30.76% of the male patients (n = 28) had a significantly prolonged QTc (> 450 ms), while 12.5% (n=2) of females demonstrated significant QTc prolongation (> 470 ms in females). This analysis shows that about half of all patients had QTc intervals outside of "normal". The majority of psychiatric medications have a tendency to prolong the QTc. This may also result when psychotropic medications are used in combination with other drugs. Polytherapy is common in psychiatric practice and, if not carefully monitored, can result in an increased risk of sudden death due to QTc prolongation and cardiac dysrhythmia. All patients who are receiving antipsychotics with a high risk of QTc prolongation should be screened for baseline QTc prolongation before initiating therapy. If the QTc prolongation is not correctable, psychiatrists should: 1) select medications with the least effect on the QTc interval; 2) avoid polytherapy if possible; and 3) monitor patient's EKGs closely while they are on therapy.

No. 95

Role of Ketamine in the Modern Era

Poster Presenter: Amindeep Lail, M.D.
Co-Author: Maheen Abbasi, M.D.

SUMMARY:

Suicide is one of the preventable cause of mortality in the United States. Approximately, around one million people worldwide commit suicide annually. Many risk factors could lead to suicide but, the highest prevalence is in the people suffering from mental illnesses like anxiety, depression, psychosis, etc. Recently, the use of ketamine has been an emerging trend in reducing the suicidality. Ketamine is a NMDA receptor antagonist used to induce anesthesia. Currently, it is also used in treating refractory depression and in alleviating suicidality acutely. Randomized control trials have proved that it takes 40 to 120 minutes for the ketamine to show response and the effect last for 10 to 14 days. Though ketamine is effective in reducing suicidality in patients, no clinical test is available to monitor the response. Moreover, there is limited research regarding the standard and maintenance dose of ketamine infusion. Another concern is, as ketamine is an anesthetic, it could be addictive to the patients. With the emergence of ketamine clinics in the United States, we want to express our views regarding the advantages and disadvantages of using ketamine in a clinical setting.

No. 96

Vitamin D Supplementation and Depression: A Systematic Review and Meta-Analysis

Poster Presenter: Marissa A. Flaherty, M.D.
Co-Author: Elliott Gauer, D.O.

SUMMARY:

Context: There has been an association between low vitamin D levels and depression, but it is not well established whether vitamin D supplementation improves depression symptoms. Objective: Perform a systematic review and meta-analysis of randomized controlled clinical trials to determine the effect that vitamin D supplementation has on depressive symptoms in adult patients measured by the Beck Depression Inventory and Hamilton Depression Rating Scale. Data Sources: Electronic databases (PubMed, PsycINFO) were searched in October 2016 for randomized controlled clinical trials with adult samples. Search terms included vitamin D, vitamin D2, vitamin D3, ergocalciferol, cholecalciferol, vitamin D deficiency, vitamin D insufficiency, depression, depressive disorder, and major depressive disorder. Study Selection: Eligible studies were randomized controlled clinical trials of adults that evaluated the effect that vitamin D supplementation had on depressive symptoms measured by the change in standardized depression scales. Studies including children, adolescents or pregnant patients were excluded. Multiple reviewers and consensus strategies were implemented to ensure correct application of the inclusion and exclusion criteria. Five of the fifty-six articles met selection criteria and were included in the quantitative meta-analysis. Data Extraction: Two

reviewers independently extracted data and assessed quality by investigating for sources of bias. Effect sizes were calculated and represented by standardized mean differences. Results: The quantitative meta-analysis showed that vitamin D supplementation improved depressive symptoms measured by standardized depression scales. The overall effect size was medium with an overall standardized mean difference of 0.495 (95% confidence interval 0.190–0.801; p=0.001). There was heterogeneity (?2=21.90; d.f.=6; p=0.001) likely due to the Dean et al. study with a standardized mean difference of -0.152 (95% confidence interval -0.499–0.195).1 Conclusions: This systematic review and meta-analysis shows vitamin D supplementation improves depressive symptoms and may be an important consideration in patients suffering from depression.

No. 97

Untangling Disruptive Mood Dysregulation Disorder From Bipolar Disorder, ADHD and ODD: A Systematic Review

Poster Presenter: Miky Kaushal, M.D.
Co-Authors: Lee Stevens, M.D., Shawn E. McNeil, M.D., Astik Joshi, M.D., Anuj Shukla, M.D., Punyapriya Gopal

SUMMARY:

Objective: Disruptive mood dysregulation disorder (DMDD) is sometimes misdiagnosed as Bipolar disorder, yet the two are clearly distinct. DMDD is a new disorder in the Depressive disorders in the DSM 5. Two key symptoms of DMDD include: frequent, severe, recurrent temper outbursts and a chronic irritable and/or angry mood. Both symptoms must be present for at least one year and cannot be accounted for by other mood disorders. While Bipolar disorder and DMDD are mutually exclusive, research suggests Oppositional Defiant Disorder (ODD) and Attention Deficit Hyperactivity Disorder (ADHD) can each be present with DMDD. The objectives of this review were to clarify the role of ODD and ADHD as symptoms or comorbidity with DMDD, understand behavioral symptoms of children with DMDD who also have either ADHD or ODD and present any new findings that compare DMDD and Bipolar disorder that are not currently in the DSM 5. Method: Articles were searched during July 2017 using PubMed, Medline and PsychINFO databases. The search yielded a total of 53 articles after duplicates were removed. Three articles were excluded (2 case studies and 1 review), thus leaving 51 studies to be screened. These articles were reviewed and considered eligible if they contained “Bipolar, “ADHD”, “ODD” within the abstract. After screening abstracts, 32 papers were found to be potentially relevant, and full article scans revealed 18 papers to meet the objectives of this study. Results: Papers on ADHD and DMDD could be identified into two clusters- those that investigated it as a comorbidity and those that investigated the associated symptoms between the two disorders. New but limited findings found that children with ADHD and DMDD demonstrated lack of self-control and increased bullying behaviors than children with ADHD without DMDD. Overall, findings suggest that DMDD is highly comorbid with ADHD. Majority of studies on ODD could be identified as patients having symptoms that overlap with DMDD. Specifically, studies report low percentages (eg., 3%) of children with psychological problems other than ODD that had DMDD symptoms. The present review also revealed findings that showed distinct history and prognosis patterns between DMDD and Bipolar disorder. DMDD may be associated with parental depression whereas Bipolar disorder correlated with the same illness from parents. Discussion: Behavioral symptoms that result with the interaction of DMDD and ADHD are limited and warrant further investigation. The DSM-5 identifies DMDD with Depressive Disorders, but ODD as a Disruptive, Impulse-Control, and Conduct Disorders. However, the literature shows overlap and lack of clear distinction between the two disorders. Authors from these studies have called for clearer criteria to distinguish the two disorders. Finally, emerging findings continue to further separate DMDD with Bipolar disorder with history and prognosis patterns.

No. 98

Results of Psychopharmacological Treatment of Depression in Patients With Intellectual Disabilities

Poster Presenter: Nicolaas Hendricus Bouman, M.D.

SUMMARY:

Background Evidence for the effectiveness of psychopharmacological drugs in people with

intellectual disabilities is scarce. Several studies showed that the use of these drugs in this population is nonetheless very high1, 2. As a consulting psychiatrist in an institution for people with intellectual disabilities the author is frequently consulted for questions concerning psychopharmacology. Experience after 5 years in this field learned that these questions are complex and that regular psychiatric guidelines are often of limited value. Purpose To assess the results of psychopharmacological treatment of depression in a population of patients with intellectual disabilities. Methods A retrospective chart review of all patients referred for psychiatric consultation between July 2012 and July 2016 was performed. Variables on demographics, level of intellectual functioning, psychiatric diagnoses, present psychopharmacological treatment, and advice of the consultations were gathered. Outcome was determined by the investigator based on the clinical impression during follow-up interviews by the author and rated as Good, Fair, Variable, Unchanged, or Worse. Results In total 615 patients were seen in consultation. Of these,118 patients were diagnosed with depression according to DSM-IV-TR criteria3. Age of depressed patients varied between 11.2 and 73.1 years. Level of intellectual disability varied from serious intellectual disability to average cognitive functioning with 83% in the mild and borderline range (IQ 50-85). Living arrangements were as follows: 45% own home, 24% assisted living facility, 10% long stay ward, 14% open inpatient treatment facility, and 7% crisis unit. 56% of patients had one or more comorbid psychiatric disorders with PTSS (21%) and autism (17%) as the most frequent. At the time of consultation 62% of the patients were using one or more psychopharmacological drugs and 20% an antidepressant. In 44 of the 118 depressed patients an antidepressant was started. These patients were followed up from 2 months up to 3 years although for 11 of the 44 patients (25%) no follow-up was available. The outcome of antidepressant treatment for those patients for whom follow-up was available was as follows: Good 41%, Fair 15%, Variable 18%, Unchanged 15%, and Worse 10%. The outcome in patients without (n=15) versus with (n=12) psychiatric comorbidity was: Good 48% vs 34%, Fair 29% vs 17%, Variable 10% vs 29%, Unchanged 13% vs 9%, and Worse 0% vs 11%. Discussion Psychopharmacological treatment of depression in patients with intellectual disability referred for psychiatric consultation resulted in improvement in approximately half of the patients. These results are comparable to results in non-intellectually disabled populations4. We found that absence of psychiatric comorbidity was related to better outcome. Limitations of this study are that it was a retrospective card review of a selected population without use of standardized instruments.

Finding Meaning in the Aftermath of a Lethal Suicide Attempt

Poster Presenter: Ioana Maria Horotan-Enescu, D.O. Co-Authors: Lisa Christine Young, M.D., Maria E. Aguilar, M.D., Enoch Barrios, M.D.

SUMMARY:

Finding Meaning in the Aftermath of a Lethal Suicide Attempt Co-authors Maria Aguliar, M.D., Enoch Barrios M.D., Ioana Horotan-Enescu, D.O., Lisa Young, M.D. Mr.F, a 27 –year-old Hispanic male with a past psychiatric history of chronic suicidal ideation and one previous suicide attempt but no previous documented psychiatric diagnoses. He was admitted to the psychiatric ward following a high lethality suicidal attempt consisting of bilateral wrist laceration, jugular and femoral laceration, while intoxicated, following rejection by a female. Patient underwent comprehensive psychiatric and psychological evaluation, during a two month hospitalization, when it become apparent that patient's chronic suicidal ideations began at an early age and preceded any substance experimentation. Most significant findings during his evaluation were a long history of untreated depression, the limited insight regarding his symptoms and overall psychological components of low self worth and loneliness, with intellectualization and rationalization coping skills and nihilistic thinking related to finding meaning in his life and a specific "plan B" to end his life at age 30 if he could not find a meaningful existence. In this poster, we will discuss the longitudinal and comprehensive treatment modalities Mr.F received, from inpatient acute stabilization to outpatient, the challenges and dilemmas encountered in treating this patient

experiencing existential distress and nihilistic thinking, the difficulty in helping the patient finding meaning in his existence and proposing potential solutions while minimizing practice implications.

Differences in the Specific Region of Cerebellum Volume of Patients With Major Depressive Disorder

Poster Presenter: Ji Won Kang
Co-Authors: Min-Soo Lee, M.D., Ph.D., Byung-Joo Ham, Woo-Suk Tae, Aram Kim, Gonju Shim

SUMMARY:
Background: A growing body of evidence has been suggested that morphologic changes in cerebellum may be implicated with pathophysiology of major depressive disorder (MDD). However, there have been no studies investigating structural changes in the specific segmented regions of the cerebellum of patients with MDD. The aim of this study is to investigate a difference in the volume of the specific region of cerebellum between patients with MDD and healthy controls. Methods: A total of 48 patients with MDD and 87 healthy controls participated in this study and underwent T1-weighted structural magnetic resonance imaging. We analyzed volumes of each five cerebellum regions (cerebellum I &II, cerebellum III, cerebellum IV, cerebellum V, cerebellum VI) divided by left and right and the volume of the whole cerebellum from T1-weigted image of participants using the FreeSurfer. One-way analysis of covariance was used to investigate the volume difference of total and specific regions between two groups adjusting for age, gender, education level, HDRS-17 score, duration of illness, and total intracranial cavity volume. Results: We found that the patients with MDD had significantly greater volume in the left cerebellum III region (P = 0.003) compared to healthy controls. No significant volume difference was not observed in other sub-regions of the cerebellum. The volumes of whole cerebellum between patients with MDD and healthy controls did not differ significantly. Conclusion: We observed the region-specific volume difference in cerebellum between the patients with MDD and healthy controls. The results of our study implicate that the information about structural alterations in cerebellum might provide a stepping stone toward an innovative tool to diagnose MDD.

Protective and Risk Factors for Occupational Stress Including Temperament-Character and Coping Strategy Among Employees in Charge of Civil Affairs

Poster Presenter: Sun Mi Kim, M.D., Ph.D.
Co-Authors: Hyeri Kim, M.D., Hyunchan Hwang, M.D., Doug Hyun Han, Jeong Ha Park, M.D., Ph.D., Ji Sun Hong, M.D., M.A.

SUMMARY:
Introduction Occupational stress increases socioeconomic burden by reducing productivity and increasing medical use. Previous studies focused on non-personal factors such as type and quantity of work related to occupational stress, and research on the one's temperament, personality, and cognitive-behavioral characteristics was limited. We analyzed the risk and protective factors of occupational stress including the temperament-character and major stress coping strategy among civil servant in charge of civil affairs. Methods The participants were employees of two local public organizations in Seoul. We administered questionnaires including Korean occupational stress scale (KOSS), Temperament and Character Inventory-Revised-Short Version (TCI-RS), Korean version of ways of coping questionnaire (K-WCQ) to 1,413 civil servants. The total of 924 valid responses were divided into the data from civil affair service (CAS) group (N = 604) who met clients for handling civil affairs or the data from Non-CAS group (N = 320) who didn't meet clients themselves. We selected the participants who reports higher occupational stress (HS group: above the 25th percentile of KOSS) and lower occupational stress (LS group: below the 75th percentile of KOSS), in order to find their differences in socio-demographic and psychological characteristics including temperament-character and major coping strategy. Results CAS group was more likely than Non-CAS group to report younger age (p=0.000), married (p=0.010), lower income (p=0.000), lower job grade (p=0.000), shorter duration of work (p=0.000). CAS group was more likely than Non-CAS group to use support-seeking coping strategy (p=0.03). CAS group was more likely than Non-CAS group to report higher KOSS scores (p=0.001). HS group was more likely than LS group to show being female (p=0.028) and in a middle job grade (p=0.008). In analyses for TCI, HS group was

more likely than LS group to report higher scores on Harm Avoidance (p=0.000). LS group was more likely than HS group to report higher scores on Reward Dependence (p=0.000), Persistence (p=0.000), Self-Directedness (p=0.000), and Cooperativeness (p=0.000). In analyses for coping strategies, LS group was more likely than HS group to report higher scores on problem-focused (p=0.000) and support-seeking strategies (p=0.000). Both BDI and BAI scores were greater in HS group , compared to LS group (p=0.000). Discussion The lower-stress group was less likely to avoid risk and more likely to respond sensitively to the feelings of others, endure the same pattern of behavior, have more autonomy to control oneself, and have a sense of unity. They have tendency to use active coping strategies. We can expect the prevention of occupational stress and the improvement of mental health if the individuals who are more suitable for the civil affairs are placed in the work based on the evaluation of the individual's temperament-character and stress coping strategy.

No. 102

Character Strengths as Protective or Risk Factors for Depressive Mood and Suicidality Among Korean Male and Female Employees

Poster Presenter: Hyeri Kim, M.D.
Co-Authors: Hyunchan Hwang, M.D., Doug Hyun Han, Sun Mi Kim, M.D., Ph.D., Jeong Ha Park, M.D., Ph.D., Ji Sun Hong, M.D., M.A.

SUMMARY:
BACKGROUND In positive psychology, recognizing and developing one's signature character strengths is important to promote mental health. However, there have been few studies on the association between character strengths and depressive mood and suicidality. This study evaluated the character strengths as protective or risk factors for depressive mood and suicidality among Korean employees. Methods 267 employees participated in this study. We administered questionnaires including Beck Depression Inventory-II (BDI-II), Korean version of the Mini-International Neuropsychiatric Interview (MINI) suicidality module, 24 Character Strength Alphas VIA Survey-72. A total of 235 valid responses was divided into three groups according to the level of depressive mood: Non-D (BDI-II?13), Mild-D (13

No. 103

A Descriptive Study of Psychiatric Patients With Intellectual and Developmental Disabilities (IDD)

Poster Presenter: Makenzie Elizabeth Hatfield Kresch

SUMMARY:
The Center for Disease Control estimates that 10.8% of the US and 14.7% of the West Virginia population has a diagnosis of Intellectual Disability and Development Disorder (IDD) (1). Although this is a significant portion of the population, literature review revealed few studies examining the psychiatric comorbid diagnoses and associated behavioral disturbances of adult patients with IDD. The only comparable study found was on adults with IDD in the United Kingdom. Results from the UK study found patients with mild-moderate IDD were more likely to have mood or personality disorders compared to severe IDD patients, who were more likely to have autism spectrum disorder, organic disorders, and behavior disorders(2). This study utilized a retrospective chart review of 100 adult patients with IDD in a psychiatric clinic in Huntington, WV. We analyzed demographic and clinical variables including psychiatric comorbidities, current psychiatric symptoms, current and past psychiatric medications, and associated medication side effects, as well as medical diagnoses and social characteristics. Data for the sample was entered into SPSS and examined. The results are presented and discussed, especially as they relate and add to the current known literature.

No. 104

Gender Bias in Mentally Ill Acute Inpatients. Beyond Diagnostic Differences in Short-Stay Mental Patients Admitted in a General Hospital

Poster Presenter: Manuel Delgado, M.D.
Co-Authors: Marta Carmona-Osorio, Carlos González-Juárez, Andrés Suárez-Velázquez

SUMMARY:
Gender bias is a well-known fact in diagnosis and care of mental health disorders. Epidemiological differences are widely mentioned in scientific literature, women having a higher chance to be diagnosed from affective or anxious disorders, and men from substance abuse. Different gender

patterns of help seeking and problem disclosing have also been described. An adequate recognition of different needs and patterns, according to gender, is being suggested in recent years, in order to improve care and wellbeing, at various levels, for both men and women. We study several gender differences and characteristics in a sample including all (N= 236) mentally ill inpatients admitted in a year-period (2016) in a psychiatric ward designed for short-term, acute care. Since shifting diagnoses was one of our main concerns, we retrospectively reviewed histories from all patients in the sample, so far back as available (up to ten years in many cases), depending on duration and onset of illnesses, and date of first contact with our mental health services. Among other differences, we found an overrepresentation of women (54/46 percent; 51/49 in general population), and also a higher number of admissions for females, while mean length of stay was higher for males. The number of diagnoses recorded in history, and changes in diagnosis were also higher in females (thus probably implying a lesser diagnostic stability, which we think should deserve further study). We discuss those and other findings and search for different proposals in order to improve diagnosis, treatment, and prognosis.

No. 105

Family First: Case Study in Early Intervention for First-Episode Psychosis: Impact of Early Family Psychoeducation When Stigma Threatens to Derail Care

Poster Presenter: Mary Duah, D.O.

SUMMARY:

NP is a 19 year old African-American female with no prior formal psychiatric history who initially presented involuntarily via mental hygiene arrest after her mother observed her behavior to be bizarre. On initial presentation NP was catatonic-non verbal and would stand in one position for hours at a time. She refused all PO intake (both solids and liquids) and when symptoms were briefly alleviated by IM Ativan she exhibited signs of responding to internal stimuli and would read aloud from a Bible, uninterruptible by any environmental stimuli. Later in her care the decision was made to start Risperdal. Unfortunately, her mother objected to this approach because of her strong belief that her daughter was possessed by the devil and needed prayer. The mother pressed the patient to refuse Risperdal urging that it was a medication used in "crazy" people with schizophrenia, could result in serious debilitating side effects and even cause her daughter to develop schizophrenic symptoms. The mother however permitted her daughter to only accept Ativan. The patients' team sought an ethics consult and legal course was encouraged if the mothers' actions led to withholding psychiatric treatment necessary to protect life. Thereafter the team determined that the best course of action would be to expedite acute care rather than a lengthy legal process. To do this the team was challenged with helping the patients' mother and family reframe their perception of psychosis in way which removed stigma and made way for much needed treatment. Ultimately the approach taken by the team was to provide family psychoeducation from a basic neurobiological and psychopharmacological angle without challenging the families' religious beliefs or using words like "psychosis", "schizophrenia" or "mental illness". Upon the completion of the family meeting, the patients' family was brought to ease with a fundamental understanding of the disease process their loved one was enduring and consequently allowed treatment to proceed with Risperdal and later Zyprexa as well as continue Ativan. As treatment progressed, there was successful collaboration between the patients' family and the team. After several weeks of inpatient treatment, the patient was discharged and later enrolled in an early psychosis program called OnTrackNY. Her family continues to attend family psychoeducation programs and the patient has successfully returned to achieving her academic ambitions. This case emphasizes the importance of understanding social beliefs and stigma associated with psychotic illnesses and how implementing family psychoeducation as part of the early intervention approach to caring for patients with early episode psychosis, can improve long term outcome for the patient as well as the family.

No. 106

Abrupt Transition of Patients With Serious Mental Illness: Outcomes of Rapid Transition of SMI Patients From Training Program Environment

Poster Presenter: Michael Henri Langley-Degroot,

M.D.
Co-Authors: Lawrence Malak, M.D., Steve Hyun Koh, M.D.

SUMMARY:
Objective: The sudden closure of a county-funded outpatient psychiatric services clinic that has been treating Medicaid patients in San Diego County for over four-decades resulted in a significant interruption in continuity of care for 758 patients with SMI and Co-occurring Disorders. Patients were served by residents as part of their core PGY3 clinical experience. The closure presented an opportunity for naturalistic study on how this loss of care continuity affects patient outcomes. We will evaluate and compare outcomes in the six months pre- and post- clinic closure. Design: A retrospective study on the impact of the clinic closure. Setting: A comprehensive, outpatient psychiatric services clinic funded by the County of San Diego Behavioral Health Services and administered by UC San Diego Health's psychiatry services. Main Outcome Measures: Missed appointments, dropouts, emergency room presentations, inpatient psychiatric admissions, and suicide attempts. Results and Conclusions: To be determined pending analysis of data.

No. 107
Exploring the Role of Youtube in Delivering Psychoeducation to the Chinese-American Community
Poster Presenter: Nikki Lam

SUMMARY:
Objective: Social media is becoming an important communication tool that can bridge the gap between health care and ethnic minorities over cultural and language barriers. Our study explores the role of YouTube in delivering schizophrenia education to Chinese American immigrants. Methods: Three psychoeducational YouTube videos related to schizophrenia were uploaded. Data from each video were collected for the year of 2016 (a 12-month period), and results were analyzed using descriptive statistics. Results: The three videos recorded 4935 views with a total viewing time of 35,614 minutes. The video regarding first-episode psychosis had the most number of views and shares, and the longest total watch time and average view duration. The targeted age group (<34 years old) comprised about half of the views for each video. Viewers of the first-episode psychosis video who were between 25 and 34 years old had a longer average view duration compared to the overall average. YouTube suggested videos were the most common traffic source (81.4%) compared to YouTube search and direct links. Conclusion: YouTube is an attractive format for disseminating schizophrenia educational contents to younger Chinese-speaking immigrants. It can also be an avenue for alleviating negative stigma regarding schizophrenia and other mental health issues among Chinese immigrants.

No. 108
Assessing a Cost-Effective Approach to Increasing Discussions About Medication Adherence in an Outpatient Psychiatric Setting
Poster Presenter: Otega T. Edukuye, M.D.
Co-Author: Christopher R. Smith, M.D.

SUMMARY:
In psychiatry, poor adherence accounts for a large portion of all medication-related hospital admissions and influences disease progression, death rates, and health care costs. In light of these growing issues, the necessity for assessing patients for adherence is evident. A preliminary literature review of existing interventions and screening measures for medication adherence in outpatient mental health facilities was conducted. This review yielded studies related to interventions utilizing more automated and often costly interventions (e.g., electronic monitoring), with very few comparative studies of less costly interventions. Efforts that aim to increase the likelihood of proactive screening of patients by prescribing clinicians has significant patient safety and quality improvement implications. Studies have shown that clinician-patient alliance and communication are associated with more favorable patient adherence. Motivational interviewing is a low cost intervention for increasing therapeutic alliance. This project aims to encourage discussions about medication adherence during medication reconciliation at routine medication management appointments in a large, urban public hospital. The improvement initiative included an informative webinar on using motivational interviewing to

improve medication adherence that was made available on demand as asynchronous learning. In addition, reminder cards of helpful interview question probes were given to all prescribers in the clinic. Prescribers were invited to complete a survey to assess knowledge about adherence, comfort with engaging patients to assess adherence, and self-reported practice change. Survey results are presented with comparative analysis of providers who viewed the webinar versus those who did not. These results may be useful to other practices seeking to improve clinical outcomes by increasing medication adherence.

No. 109

Impact of the Deepwater Horizon Oil Spill on Adult Alcohol Use and Posttraumatic Stress Symptoms

Poster Presenter: Robert Marcus Fuchs
Co-Author: Joy Osofsky, Ph.D.

SUMMARY:

Background: The Deepwater Horizon Oil Spill of 2010 had a devastating impact on residents of southeastern Louisiana. Individuals affected by this technological disaster experienced challenges related to physical injury, emotional strain, and financial burden. The medical conditions acquired secondary to this disaster have been described previously, revealing that a number of acute and chronic conditions were developed by those directly or indirectly exposed to contaminated water. However, the chronic psychiatric sequelae of exposure to the Deepwater spill, such as posttraumatic stress disorder (PTSD) and increased substance use, have not been satisfactorily investigated. Existing literature indicates that PTSD and anxiety both increase following technological disaster (as in those whose lives were affected by the 1989 Exxon Valdez oil spill) one year after the exposure, but little is known about changes to substance use (Solomon et al. 2010; Palinkas et al. 1993). Based on this background, an investigation into the psychological outcomes of victims of the Deepwater Horizon Oil Spill is highly prudent to improving community treatment of psychiatric illness in the Southeastern United States. Methods: To enable study of our unique population, the Department of Psychiatry at Louisiana State University Health Sciences Center developed and administered a survey entitled the "Deepwater Horizon Event Psychosocial Needs Assessment". This survey was administered to 300 adults (at least 18 years of age) within the New Orleans metropolitan area. This method of interview provided valuable self-reported data across a wide variety of psychosocial items, including emotional burden (e.g. anger, loneliness, and financial strain), physical and psychosomatic symptoms (e.g. headache), and substance use. Critically, this survey collected information about the magnitude of exposure to the disaster, and asked participants to report changes in emotional state both before and after exposure to the oil spill. These features of our survey facilitate interpretation of how the degree of disaster exposure causes psychiatric and psychological dysfunction. Results: We will use SPSS to generate logistic and multiple regressions based on magnitude of disaster exposure. This approach will allow us to test the hypothesis that individuals highly affected by the oil spill develop higher levels of PTSD-like symptoms (e.g., anxiety) and substance use. The findings of this study will reveal how this type of technological disaster can affect regional communities, in turn providing crucial information to trauma-oriented health services and organizations about the value of long-term psychiatric follow up for disaster victims.

Refugee Health and Wellness: Sharing Our Success With Medical Student-Run Refugee Health Fairs

Poster Presenter: Sally Huang
Co-Author: Sophia Banu, M.D.

SUMMARY:

Purpose: Each year, medical students at Baylor College of Medicine (BCM) in Houston, Texas, organize a refugee health fair to promote refugee health and wellness in partnership with the Alliance for Multicultural Community Services (AMCS), a local refugee resettlement agency. Refugees face significant barriers in language acquisition, employment, transportation, and access to medical and mental health services upon arrival in their new home; previous trauma can further exacerbate the stress naturally induced by the resettlement process. These fairs empower refugees to take control of their own health by establishing a medical home as

an important part of the resettlement process. Medical students organize this student-run fair with mentorship by BCM psychiatry faculty, and we offer our experiences as a replicable model for other medical students and healthcare professionals interested in refugee or public health. Methods: A committee of medical students organized two refugee health fairs in the 2016-2017 academic year, supported by the TMAF Medical Student Community Leadership Grant and BCM. Committee tasks included recruiting volunteers and translators; communicating with students and faculty from other medical, dental, pharmacy, optometry schools, and universities in the Texas Medical Center, as well as AMCS; forming partnerships with community organizations; and coordinating logistics on the day of the event. We held two volunteer trainings before each fair, paying particular attention to issues unique to the refugee population. Results: Over 300 clients were seen at the two fairs. At each fair, more than 120 volunteers provided over 6000 free mental health, medical, dental, and ophthalmological preventative screening services; educated refugees about preventative health; and connected clients with resources in the Houston area. Case managers from AMCS and community members provided critical translation services for clients who attended. Student and faculty volunteers came from seven undergraduate and professional institutions in the Texas Medical Center. Local clinics and organizations like the Center for International Trauma Survivors, Texas Children's Hospital Mobile Vaccine Clinic, Houston Food Bank, and the Houston Area Women's Center, amongst others, were present to connect with clients and offer their services. Conclusion: These health fairs are often points of first contact between the client and mental health or medical services beyond their initial arrival health screen. Our experience demonstrates that medical students can play an important role in helping refugees establish a medical home in the often-chaotic resettlement process, and this inter-institutional approach indicates significant interest in refugee health among professional students, as the experience is both professionally enriching for us as we gain experience working with large, multinational populations, and beneficial for the clients whom we serve.

No. 111

Readmission Reduction Strategies at a Regional Academic Medical Center

Poster Presenter: Seema Sannesy, M.D.

SUMMARY:

Repeated psychiatric hospitalization, primarily for those with serious mental illness, continues to be a problem nationally. While much focus has been given to finding the balance between length of stay (LOS) and 30-day readmission rate, the factors that influence readmission rates appear to be multiple. Identifiable reasons for psychiatric readmission include, but are not limited to, history of previous admission, premature discharge, inadequate transition support services after discharge, nonadherence with aftercare and/or medications, or simply discharge plan failure. In efforts to reduce 30-day inpatient psychiatric readmissions a regional academic medical center in New York State's Hudson Valley has employed a number of strategies. Integral to this initiative has been joining the Readmissions Quality Collaborative (RQC) sponsored by the NYS Office of Mental Health, the Healthcare Association of NYS, and the Greater NY Hospital Association, along with formation of a multidisciplinary Behavioral Health Readmissions Reduction Committee within the medical center. Baseline data analysis of readmissions included the examined variables of LOS, reason for readmission, discharge referral, and whether initial aftercare appointment was kept. Quarterly analyses have been completed as various readmission reduction strategies were employed over time. These strategies thus far have included introduction of a readmission risk assessment form to be completed at the time of intake, Psychiatric Services and Clinical Knowledge Enhancement System (PSYCKES) access for clinicians, warm handoffs prior to discharge, bedside prescription delivery, a single organized folder provided to patients at the time of discharge containing discharge and aftercare instructions, an outlined readmission reduction plan as part of discharge documentation, post discharge follow-up calls to patients and outreach calls to aftercare providers, and introduction of a social worker/care manager in the psychiatric emergency department setting to facilitate short-term alternatives to

psychiatric hospitalization. These strategies are presented and evaluated with regards to their effects on quarterly data analysis of readmission rates, along with specific barriers noted.

No. 112

Mass Psychogenic Illness in a School Following an Anniversary Day of Mega Earthquake in Nepal

Poster Presenter: Hitekshya Nepal, M.D.

SUMMARY:

Background: Mass psychogenic illness (MPI) is defined as the manifestation of organic symptoms without a defined cause in a group of people who share similar beliefs about the underlying cause of the symptoms. Despite being rare, it usually gathers great attention in media and public health outputs. Also, it poses a significant health and social impact, through its association with social stigma. This study was conducted in a rural school in Nepal to investigate the symptoms of MPI following the mega-earthquake in 2015. Methods: In 2015, a mega earthquake hit Nepal. One year later, a student X (index case) fainted in class followed by 37 other students who had witnessed the index case, on the anniversary day of the earthquake. All students were followed up for 12 weeks to assess their symptomatology and study the risk factors. Results: A total of 38 female students of age groups 12-16 who showed the symptoms consistent to conversion disorder. Majority (86.5%) of students belonged to poor socioeconomic and illiterate families. Social belief about being possessed by evil spirit behind the school was proposed as cause of this abnormal behavior by the previously well children. The study also revealed earthquake related stress being the major precipitating factor due to the fact that this incident occurred following day of anniversary of mega earthquake. Almost all the girls had lost either one or more family member, house, domestic animals and other property during earthquake. Psycho-education and psychotherapy was the main stay of treatment. Intervention was done at both individual and community level. Parents, school teachers and key stakeholders of the community were educated regarding the nature, cause, symptoms and management of illness. During 6 weeks follow up, only 2 cases were reported to have symptoms of conversion disorder. Stress regarding the homework and poor school performance was identified on both girls. Intervention was done accordingly and 12 weeks follow up reveled symptoms free to all students. Conclusion: MPI is mostly prevailed in developing countries and management of this condition should be done in accordance with socio-cultural context. Our aim is to make physicians aware on the diverse presentation of MPI and make local resources available even in rural communities where such conditions are more prevalent.

No. 113

Hypothyroidism Masquerading as Psychosis: An Unusual Presentation in a 14-Year-Old Boy

Poster Presenter: Hitekshya Nepal, M.D.

SUMMARY:

It is a well known fact that thyroid hormone is essential for growth and development in children. Deficiency of the hormone produces multi systemic effects. The varied manifestation could be from global developmental abnormalities to acute metabolic derangement which vary according to age as well. Psychiatric manifestation could vary from cognitive dysfunction, mild attentional impairment to affective disorders, agitated delirium and psychosis. We present an unusual case of hypothyroidism in a 14 years old boy who presented with the complaint of hearing voices like a radio talking for three weeks. This was not heard by other people around him. He then developed sleep disturbance, inability to concentrate and progressive agitation. On exam, vital signs was temperature of 97.7°F (36.5°C), a pulse of 60 beats/min, and blood pressure of 100/76 mm Hg. Physical exam revealed short stature, dry skin, reduced pubic hair, and gynaecomastia. His heart and lung examinations were unremarkable. He had a normal-size thyroid gland. His neurologic examination was normal strength in all extremities with a significant delay in the relaxation phase of the deep tendon reflexes. He was alert and oriented but with notable auditory hallucinations during the examination. Investigation revealed markedly increase thyroid stimulating hormone (TSH) 98.4 μU/mL (reference range: 0.50–5.00 μU/mL) and thyroxine (T4) level of less than 1.0 μg/dL (reference range: 4.5–10.9 μg/dL), and total triiodothyronine (T3) level of 24 ng/dL (reference

range: 60–181 ng/dL) and positive thyroid autoantibody test. Substance use was ruled out. Thyroid replacement treatment (thyroxin) was initiated with a low dose of Risperidone. Significant improvement in symptoms including auditory hallucination was observed in 2 weeks period and he was asymptomatic in 4 weeks. The Risperidone was gradually stopped with complete resolution of hallucination. TSH was dramatically decreased over 4 weeks. Repeat thyroid function test at 8 weeks was within normal limits. The case illustrates the importance of thyroid function test as a routine part of psychiatric assessment in child and adolescent psychiatry. And to consider hypothyroidism for new onset psychosis. This could help to identify and manage such cases at the earliest. This would ultimately prevent associated morbidity and mortality.

No. 114

A Case Presentation of Late Diagnosis of Schizophrenia and Discussion of the Literature of Schizophrenia in the Older Adult Population

Poster Presenter: Albert Nguyen, D.O.
Co-Author: Shane Verhoef

SUMMARY:
With epidemiological studies showing that onset of psychotic symptoms and diagnosis occur usually during early adolescence and early adult life, a diagnosis of schizophrenia made later in life is less common. Additionally, the diagnosis may be complicated by the presenting psychotic symptoms being obscured in the older adult population due to multiple comorbidities associated with advancing age. Hence, there is a broad differential when psychotic symptoms (paranoia, hallucinations, delusions) present later in life that include delirium, psychosis related to neurodegenerative diseases, psychosis due to general or medical condition, mood disorder with psychotic features, substance induced psychosis, delusional disorder, and schizophrenia spectrum disorder. Primary work up of psychosis in the older adult population and elderly generally focuses on a comprehensive medical evaluation to rule out underlying organic pathology. This poster will present a case of a diagnosis of schizophrenia made later in life in a 60 year old high functioning older gentleman who was admitted to the geriatric inpatient psychiatry unit for bizarre behavior, auditory hallucinations, paranoia, and disorganized speech and thinking. He underwent a medical work up for acute psychotic symptoms and altered mental status that was predominantly negative. This case will help illuminate the importance of recognizing that late presentation of schizophrenia is more common and prevalent than typically believed, and should be an important differential diagnosis. This case will also help facilitate discussion and review the literature concerning epidemiology, clinical presentation, risk factors, and diagnosis in later life schizophrenia and late onset and very late onset schizophrenia.

No. 115

Maintenance rTMS in a Multiple Sclerosis Patient With Resistant Depression: A Case Report

Poster Presenter: Yamini Samy
Co-Authors: Antony Fernandez, M.D., Chinna Samy

SUMMARY:
Multiple sclerosis (MS) is a disabling neurological disorder presenting a variety of symptoms which are hard to control by actual drug regimens. Non-invasive brain stimulation techniques such as rTMS have been investigated in past years for the improvement of several neurologic and psychiatric disorders. Major depression a common co-morbid condition in MS could modify the outcome of treatment of both MS and depression. We describe the application of transcranial magnetic stimulation (rTMS) in an MS patient with resistant depression. The patient was treated with rTMS and continued on maintenance rTMS treatments on follow up. Clinical outcome measures on HAM-D, BDI and QOL at baseline and on follow up demonstrate that improvement was sustained during follow up. Neuroimaging data showing evidence of relapsing and remitting MS will be displayed. The durability of TMS' antidepressant benefit and safety and tolerability profile make it an attractive treatment option for selected patients. Although TMS is labor intensive compared with medications, its efficacy, safety, and tolerability for depression and comorbid neuropsychiatric disorders are driving additional research to refine and improve its therapeutic appeal.

No. 116

Neuropsychiatric Manifestation in a Patient With Panhypopituitarism

Poster Presenter: Oluwole Jegede, M.D.
Co-Authors: Ayodeji Jolayemi, M.D., Mario Gustave, M.D., Heela Azizi

SUMMARY:

Introduction: The pathophysiologic presentation of panhypopituitarism is well documented but there is a paucity of data on its possible associated neuropsychiatric manifestations. Cases described in literature involve psychotic presentations following panhypopituitarism from various etiologies including an ectopic posterior pituitary, Russell Viper Bite, Sheehan's syndrome, Traumatic Brain Injury (TBI), and after glucocorticoid therapy. Case Presentation: We present a case of an incidental diagnosis of panhypopituitarism in a 68-year-old African American man admitted to our psychiatric inpatient unit with symptoms diagnostic of schizophrenia. The case was unusual as a first-episode psychosis given the patient's age, in the absence of any known psychiatric history. In the course of his admission, the patient's clinical condition deteriorated culminating in a sudden altered mental status which prompted a transfer to the medical floors and further investigations. A head CT scan and a pituitary MRI revealed a near total resection of the pituitary while laboratory investigations revealed hyponatremia and a grossly low hormone profile. The progression of these events casts doubts on our admitting diagnosis as the primary cause of the patient's symptoms. The patient's clinical condition improved only when his endocrinopathy was treated with hormone replacement, fluids, and electrolyte correction in addition to antipsychotics. An inability to verify the patient's psychiatric history and a remote history of pituitary resection several decades earlier, unknown to the treating team, added to the diagnostic conundrum. We revised the diagnosis to neuropsychiatric manifestations secondary to an organic brain syndrome due to a partial pituitary resection. The patient was discharged with no symptoms of psychosis, good insight, judgment, and good reality testing. Discussion: Mechanisms for the pathogenesis of psychosis in hypopituitarism may be a result of interactions between pituitary hormones and the dominant neurotransmitters: serotonin, dopamine, GABA, and glutamate and a complex metabolic and electrolyte changes in the central nervous system resulting from a combination of hypothyroidism, hypoglycemia, and low cortisol. The etiology of psychosis in our patient is difficult to ascertain for two main reasons: one, our inability to obtain a comprehensive psychiatric and medical history on admission, and two, the relatively late onset of psychosis and his history of being symptom-free for so many years following the pituitary resection. These factors make it problematic to rule out an underlying psychotic disorder; however, it is of clinical significance that, once we added hormone supplementation to the patient's medication regimen, the patient made remarkable clinical progress.

The Psychiatrist Who Forgot Who He Was: A Case of Posttraumatic Autobiographical Memory Loss With Structurally Intact Hippocampus

Poster Presenter: Oluwole Jegede, M.D.
Co-Authors: Carol Lim, M.D., M.P.H., Olawale Ojo, M.D., Ayotomide E. Oyelakin, M.D., M.P.H., Alexa B. Kahn, Sherina Langdon, Justin Jonghyun Shin, Priya Mukhopadhyay, Devashree Parmar, Ruby Sangha, Ayodeji Jolayemi, M.D.

SUMMARY:

Introduction: The famous case of Henry Molaison has been pivotal to understanding the human brain and has provided important scientific framework for the organization and distribution of memory functions as well as theories involving memory consolidation, storage, and retrieval. Here we present a similar case observed on our inpatient unit of a patient who reported to be a psychiatrist, with similar patterns of memory loss but without any structural hippocampal changes. Case Summary: This is the case of a 44-year-old man, who claims to be a psychiatrist, the patient demonstrated anterograde and retrograde amnesia following a motor vehicle accident but his general semantic memory appears preserved. The patient also lost his personal autobiographical memory including his native language, but with a retention of his secondary language, English. Interestingly, the patient demonstrated an intact and extensive knowledge of

psychiatric principles and practice as well as a profound fund of medical knowledge. The patient's pattern of memory loss closely resembles that of the famous case of Henry Molaison, who was the basis for the Hippocampal theory of Memory storage. Henry Molaison underwent bilateral medial temporal lobe resection and had complete loss of memory of events subsequent to the surgery and a partial retrograde amnesia in the absence of changes in personality or semantic knowledge. To the best of our knowledge, this is the first reported case of a patient with the similar pattern of memory loss as Henry Molaison, yet without any history of neurosurgery or any structural or anatomical lesion on CT and MRI. Discussion: This case is unique as it demonstrates a similar pattern of memory loss as the famous case of Henry Molaison in the absence of any evidence of lobectomy of medial temporal lobes. Henry Molaison demonstrated extensive damage to the entorhinal and perirhinal cortices accompanying the severe impairment of autobiographical memory. We suggest a possible model of hippocampal neural networks, demonstrating inhibition of neurons which may account for the memory loss, even without any gross neural damage. Such a model of neural network model is based on the hippocampus acting at an integration center, during the process of learning and retrieving polymodal information of two cortical pathways coding for individual stimuli assemblages and abstract entities. This concept of inhibition has been observed in prior experiments on the dentate gyrus of the hippocampus, and may explain the patient's autobiographical memory loss while maintaining intact and impressive fund of medical knowledge.

No. 118

Activation of Symptom Dimensions in Obsessive-Compulsive Disorder During Working Memory and Sustained Attention

Poster Presenter: Ella Hong, M.D.

SUMMARY:

Obsessive–compulsive disorder (OCD) exhibits heterogeneous symptoms and are noted to have a broad range of comorbid disorders. The Dimensional Yale–Brown Obsessive–Compulsive Scale (DY-BOCS) was introduced as a clinical metric for assessing the presence and severity of six specific OC symptom dimensions that combine thematically related obsessions and compulsions. The current study aims to explore the six symptomatic dimensions of DYBOCS as predictions of fMRI estimated activation in OCD using both an n-back paradigm (for working memory) and Continuous Performance Task (for sustained attention) to assess whether activation profiles are predicted by symptom clusters.

No. 119

New-Onset Behavioral Changes and Visual Disturbance: A Case Study and Discussion

Poster Presenter: Jamon Aaron Holzhouser, M.D.

SUMMARY:

30 year old male member of the USMC with a history of a combat deployment, previous contact with behavioral health for unspecified depression and anxiety, and ongoing marital problems, who was referred to the partial hospitalization program at Walter Reed from his outpatient provider in Guantanamo Bay, Cuba for increasing suicidal and homicidal thoughts which frequently were precipitated by some benign interpersonal interaction or minor aggravation. Although he denied active suicidality, he had a persistent wish to die. His mood disturbance and suicidality were largely refractory to pharmacological and psychotherapy. After approximately two weeks, he revealed that for the preceding month, he had been experiencing diplopia intermittently, for about five minutes, which would then spontaneously resolve. He was referred to ophthalmology to evaluate his diplopia, and after confirming it, ordered an MRI. This revealed an 8 cm Left Temporal and Left Frontal lobe mass which was causing uncal and subfalcine herniation. He was admitted to the hospital immediately and eventually received a biopsy and ultimately 95% resection of what was determined to be a glioblastoma. After the resection he underwent radiation treatment. Interestingly, his neurological symptoms remained initially unchanged until ultimately his CNIV lesion began to resolve. However, his psychiatric symptoms remained unchanged. He continues to have suicidal and homicidal ideation routinely, and in response to minimal provocation. He most recently reported thoughts of murdering his wife and child before taking his own life.

Parkinson's Disease, Cognition, and Language
Poster Presenter: Maria Kralova

SUMMARY:
Cognitive disorders – mild cognitive impairment (MCI) and dementia – are of the most prevalent nonmotoric features of Parkinson's disease (PD). MCI patients with Parkinson's disease develop dementia approximately six times more often than the age-matched PD patients without MCI. The prevalence of dementia after 15-20 years duration of PD is relatively high, so the current research is focused on identification of any early markers of cognitive disturbances, which can potentially progress to dementia. We offer the first results of our research, focused on the analysis of cognitive-communication disturbances in Parkinson's disease. This poster presents the prevalence of cognitive disorders in the sample of PD patients, characteristics and profiles of cognitive disturbance in PD, the relationship between cognitive decline and verbal-language abilities and besides evaluation of so called "cold cognition" also the disturbances of social cognition in PD.

No. 122
Mediagenic Psychosis in Dementia: A Case Report
Poster Presenter: Noha Mohamed Rady Abdel Gawad, M.D.
Lead Author: Garima Arora, M.D., M.S.

SUMMARY:
We present the case of a 90 year old male patient, with Alzheimer's dementia and normal pressure hydrocephalus (NPH) who exhibited new onset delusional pseudotranssexualism in the context of mediagenic psychosis. 'Mediagenic psychosis' refers to the incorporation of emotionally laden stressful news items from the media into patients' delusional systems [1, 2]. The emergence of the patient's delusional beliefs coincided with the airing of a popular television show portraying a transsexual celebrity.Commonly reported delusional content in dementia includes paranoid delusions, delusions of persecution, theft, and infidelity [3]; and less common are delusions of erotomania [4] and delusions of pregnancy [5]. Delusional pseudotranssexualism has been reported in schizophrenia[6] but to our knowledge, it has not yet been reported in dementia. This lends further evidence to the role of concurrent sociocultural and political issues in shaping delusional thought content in psychosis.

No. 123
Serum Complement C3 Mediates Education's Effect on Cognition
Poster Presenter: Safa Rubaye, M.D.

SUMMARY:
Background: The latent variable "d" (for "dementia") appears to be uniquely responsible for the dementing aspects of cognitive impairment (Gavett el al., 2015). Age, depression, and the apolipoprotein E (APOE) e4 allele are independently associated with d (Royall et al., 2013). On the other hand, education, especially in young age, plays a role in lowering the risk of dementia including Alzheimer's Disease (AD) (Meng et al, 2012; Basu 2013). In this analysis, we combine SEM (Structural Equation Model) with longitudinal data from the Texas Alzheimer's Research and Care Consortium (TARCC) to explore Complement C3 as a possible biomarker of education's specific effect on d. Participants and Method: We employed structural equation models (SEM) to examine the mediation effect of S100b on depression's association with d in a well characterized cohort, the Texas Alzheimer's Research and Care Consortium (TARCC). Subjects included n= 3385 TARCC participants [1240 cases of Alzheimer's Disease, 688 "Mild Cognitive Impairment "(MCI) cases, and 1384 normal controls (NC)]. Serum biomarkers levels were determined at baseline by Luminex assay (Rules Based Medicine /Austin, TX). All observed measures were adjusted for depression, ethnicity, gender, Geriatric Depression Scale (GDS) scores, Hb1Ac, apoE4 and HCY. Biomarkers were additionally adjusted for batch effects. We used an ethnicity equivalent d homolog (i.e., "dEQ"). Wave 2 dEQ scores were used. Thus, the model is longitudinal and arguable causal. Furthermore, we randomly divided the cohort into 2 groups. Group A (n = 1691) was used to construct the model, while

Group B (n=1694) was used to replicate and verify the parameters of interest. Analyses were conducted in Analysis of Moment Structures (AMOS). Results: Model fit was excellent [?2 = 514.673(49), p =0.0; CFI = 0.891; RMSEA = 0.053]. Serum C3 was found to mediate 16.5% of Educations association with Wave 2 dEQ scores (p<0.001) (Table 1). The effect generalized across random subsets of TARCC's sample. Discussion: CSF C3 levels are associated with AD severity (Wang el al 2011). It has a role in phagocytosis of fibrillar amyloid B by microglia (Fu el al 2010). Education is a protective factor for developing AD. This protective role is partially mediated by C3. Complement C3 plays a role in mediating Education's independent effects on dementia severity.

No. 124

Challenges in Management of Behavioral Agitation Secondary to Probable Sporadic Creutzfeldt-Jakob Disease

Poster Presenter: Yiqin Xu

SUMMARY:

Mr H. is a 84 year old Caucasian male with no past psychiatric history and a medical history significant for parkinsonian gait and atrial fibrillation(status post pacemaker), who was admitted to the family medicine inpatient service due to a 4 week decline in his mental status beginning with expressive aphasia, babbling, confusion, suspected auditory hallucinations, progressing to displays of bizarre behaviors such as stomping barefoot in mud and threatening son with pitchfork while wearing nothing but 4 pairs of underwear. Differential diagnoses were broad including Lewy body dementia, corticobasal degeneration, subclinical seizures, prion disease, and paraneoplastic encephalitis. During the first 5 days of hospitalization Mr. H continued to exhibit violent behavior including pinching, punching family members and staff, on a daily basis that required physical restraints in addition to acute treatment with multiple antipsychotics. Concomitant use of standing Seroquel and PRN IM Haldol for acute exacerbations was successful in reducing the frequency of violent outbursts. Following the initiation of treatment, his mental status was significant for periods of lucidity and jovial affect interspersed with infrequent acute violent agitation. Latter episodes of agitation were responsive to non-pharmacologic interventions including optimization of his hearing aids and frequent reorientation. The extensive medical work up ultimately confirmed the diagnosis of prion disease (suspected sporadic Creutzfeldt-Jakob Disease). In this poster, we will discuss the challenges and successes of Seroquel and nonpharmacologic interventions in symptomatic management of rapidly progressive prion disease.

No. 125

Genetic Link and Treatment Challenges Between Schizophrenia, Marfan's Syndrome and Polycystic Kidney Disease

Poster Presenter: Modupe Ebunoluwa James, M.D.
Co-Authors: Charles Rodolphe Odom, M.D., Michael Burescu, Luisa S. Gonzalez, M.D.

SUMMARY:

Marfan's Syndrome (Marfan's) is caused by a mutation in the Fibrillin 1 gene on chromosome 15. This leads to failed transforming growth factor beta (TGF-B) signaling which is believed to be one of the targets for the aberrant TGF-B signaling in the brain and this is what predisposes the Marfan's patient to schizophrenia (1). Another genetic finding indicates that Marfan's has a co-occurrence to the Polycystic Kidney Disease (PKD) 1 locus shared with PKD. Research studies also imply that mutations of the dystrobrevin gene have been linked between PKD and Schizophrenia. Consistent findings of this connection has lead researchers to believe that Marfan Syndrome and Schizophrenia are occurring together at a higher rate than expected, specifically if the patient has co-morbid PKD. We present a case of a 50-year-old, schizophrenic man, who upon admission to the inpatient psychiatric unit was disorganized, paranoid and agitated in the context of noncompliance with medication. There was no diagnosis of Marfan's syndrome or PKD prior to his admission. After several studies and assessments, with collaboration of the multiple departments, the diagnosis was confirmed. Due to the complexities in our case this led us to conduct a literature review to discern the possible genetic connections between the patient's psychiatric diagnosis and his medical co-morbidities. Managing non complaint schizophrenic patients can be challenging due to the

lack of insight into their medical and psychiatric condition. Marfan's involves different organ systems and requires meticulous follow-up with cardiology, nephrology and the ophthalmology service. A multidisciplinary team approach is recommended for these complex cases to ensure adequate and timely care. Understanding the genetic relationship between Marfan's, PKD, and schizophrenia warrants further attention in order to improve current knowledge and clarify a possible common etiology

No. 126

Genes Involved in Neurodevelopment, Neuroplasticity, and Bipolar Disorder: CACNA1C, CHRNA1, and MAPK1

Poster Presenter: Taeyoun Jun, M.D.
Co-Author: Sungjune Bae

SUMMARY:

Background: Bipolar disorder (BPD) is a common and severe mental disorder. The involvement of genetic factors in the pathophysiology of BPD is well known. In the present study, we tested the association of several single-nucleotide polymorphisms (SNPs) within 3 strong candidate genes (CACNA1C, CHRNA7, and MAPK1) with BPD. These genes are involved in monoamine-related pathways, as well as in dendrite development, neuronal survival, synaptic plasticity, and memory/learning. Methods: One hundred and thirty two subjects diagnosed with BPD and 326 healthy controls of Korean ancestry were genotyped for 40 SNPs within CACNA1C, CHRNA17, and MAPK1. Distribution of alleles and block of haplotypes within each gene were compared in cases and controls. Interactions between variants in different loci were also tested. Results: Significant differences in the distribution of alleles between the cases and controls were detected for rs1016388 within CACNA1C, rs1514250, rs2337980, rs6494223, rs3826029 and rs4779565 within CHRNA7, and rs8136867 within MAPK1. Haplotype analyses also confirmed an involvement of variations within these genes in BPD. Finally, exploratory epistatic analyses demonstrated potential interactive effects, especially regarding variations in CACNA1C and CHRNA7. Conclusion: Our data suggest a possible role of these 3 genes in BPD. Alterations of 1 or more common brain pathways (e.g., neurodevelopment and neuroplasticity, calcium signaling) may explain the obtained results.
Acknowledgment This study was supported by a grant of the Korean Health Technology R & D Project, Ministry of Health & Welfare, Republic of Korea (HI12C0003).

No. 127

Are Psychiatric Conditions and Medications a Risk Factor for Delirium?

Poster Presenter: Victor G. Patron Romero, M.D.

SUMMARY:

Delirium is an acute onset of cerebral dysfunction, in which a change from baseline cognition can be seen, including inattention, changes in level of consciousness or disorganized thinking. [1] Delirium can go unrecognized in up to 32-66% of hospitalized patients [2] and it has been estimated a cost ranges from $38-162 billion per year [3]. Many studies have measured incidence and prevalence of delirium in correlation with surgical intervention, and although a correlation with depression and depressive symptoms has been seen [4,5], studies identifying more specific mechanisms underlying the relationship between delirium and psychiatric diagnoses are lacking; furthermore, no studies have looked at other psychiatric conditions as risk factors for delirium and their profile of symptoms. A sample of 85 patient admitted to the hospital and diagnosed of delirium with and at least one psychiatric diagnosis including dementia was analyzed to assess psychiatric conditions and different families of psychiatric medications as risk factor or protective factor for delirium and length of hospitalization and amount of psychotropics administered. After ANOVA for psychiatric conditions including dementia, substance abuse, Bipolar disorder, depression, psychosis and different psychotropic medication there was no difference o increase risk for delirium in those with the afore mentioned psychiatric conditions, which goes against know literature listing Depression as a risk factor for delirium. When not controlling for age, depression did have an effects in longer stay in the hospital even above dementia.

The Warrior for Christ: Doctrine or Delusion?
Poster Presenter: Anindita Chakraborty, M.D.
Co-Author: Musa Yilanli, M.D.

SUMMARY:
Background: Religious beliefs are commonly seen in psychiatry and it can be challenging to disentangle what is normal versus what is pathological. The following case illustrates this challenge. Case: Mr. K is a 50 yo veteran with a history of a diagnosis of Bipolar I disorder and opiate use disorder who presented with symptoms of anxiety, restlessness and insomnia. He complained of stomach cramps and diarrhea. On mental status he appeared tremulous, hyperverbal but cooperative. He self tapered his Quetiapine and Suboxone and said "God cured my bipolar disorder!" He admitted to feeling the happiest he has been in his life. 6 months ago, he had joined an online ministry and now spends hours praying and casting out demons online. He called himself the "warrior for Christ" chosen to rid the world of Satanic spirits. His wife reported that he stopped watching TV and refused to have sex with her, calling it all "Satanic". Despite this he was able to work as a janitor. During the course of his hospital stay, patient refused all medications, except for Suboxone. His anxiety and insomnia improved, but his religious views persisted. Review of records over the past year revealed that patient presented multiple times at other VAMCs with similar symptoms after stopping his Suboxone. His symptoms would improve on restarting Suboxone but his religious views persisted. Discussion: There are no clear guidelines to differentiate religious beliefs and religious delusions. Peter et al devised an empirically validated scale called Peter's Delusions Inventory consisting of 4 measures of the delusional experience: dimensional scores for "conviction, preoccupation and distress" and a mean total score. A variety of studies among psychotic patients vs. religious and non religious controls have found that psychotic patients have higher mean total scores but there was significant overlap between ranges of mean total scores and dimensional scores. That is delusions and religious beliefs lie on a wide spectrum. Intensity of each dimension, particularly preoccupation and impaired functionality are more suggestive of psychosis. Delusional content and clinician's perceived falsity of the delusion may not help as religious experiences are subjective. Shared beliefs may argue against psychosis. True religious beliefs are persistent and do not respond to medications. Our patient's beliefs came with intense conviction and preoccupation, relieving his emotional distress and causing only partial functional impairment. His beliefs predated his stopping Quetiapine and close follow up revealed persistence of beliefs. Notably, his beliefs were never a safety concern. During admission, author felt puzzled, and wondered if this patient was psychotic purely based on the content of his beliefs. In conclusion it may be helpful to evaluate suspected religious delusions within a dimensional framework, while being cognizant of one's own beliefs to ensure therapeutic alliance.

No. 130
Barriers to Medication-Assisted Treatment in Alcohol Use Disorder: A QI Initiative Among Detroit Veterans
Poster Presenter: Anindita Chakraborty, M.D.
Co-Authors: Musa Yilanli, M.D., Daniel J. Goyes, M.D., Umair A. Daimee, M.D., Sandra Reyes, Lauren Wake, Karen M. Parisien, M.D., Nicole Stromberg, M.D.

SUMMARY:
Aims: Alcohol use disorder (AUD) is highly prevalent amongst veterans. VA DoD guidelines recommend medication assisted treatment (MAT) i.e. either Acamprosate, Disulfiram, Naltrexone or Topiramate in the treatment of moderate-severe AUD. Despite their efficacy they are not widely used. VA administrative data reveals that only 8.5% of patients with AUD in the Detroit VA, received MAT in the last 6months compared to a national average of 10.5%. Our study aims to 1) Identify barriers to using MAT for AUD 2)To design sustainable interventions to increase the percentage of patients with AUD receiving MAT to 15% over a 6month period. Methods: Using the PDSA (Plan, Do, Study, Act) framework, our first PDSA cycle introduced a 6-item questionnaire distributed to 10psychiatrists, 12 psychiatry residents and 5 primary care physicians (PCPs) at the Detroit VA. The questionnaire was self-administered, followed by a brief unstructured interview for qualitative data. We assessed rates at which MAT was prescribed and offered as well as

barriers and patient characteristics when prescribing MAT. Our survey gathered information regarding physician preferences for sustainable interventions that may lead to increased rates for prescribing MAT. Results: Physician viewpoints were stratified into attending psychiatrists, psychiatry residents and PCPs. Attendings offered MAT to an average of 60-80% of their caseload but ended up prescribing in 20-40% of cases on average. Resident's rates of offering and prescribing MAT were much lower at 0-20%. Only 1 out of 5 PCPs claimed to prescribe MAT at all. Most common medication prescribed was Naltrexone, Gabapentin was a close second though not considered first line by VA DoD guidelines. Among psychiatrists, most common barrier to prescribe MAT was non compliance with medications whereas residents' primarily cited a lack of experience. PCPs cited lack of experience as well, along with a lack of time to address AUD. The most important factors influencing prescription of MAT was patient willingness to take the medications and a willingness to quit alcohol. Provision of educational materials to patients was the most preferred QI intervention followed closely by physician education to build awareness. Conclusions: MAT treatment in AUD is underutilized and rates at the Detroit VA fall below national standards. Our first PDSA cycle concluded that the most important factors influencing prescription of MAT was a willingness to take the medications and a willingness to quit alcohol. Physicians suggested patient and physician education as most preferred interventions. Our second PDSA cycle will involve conducting a MAT workshop for physicians and distributing educational materials to patients during visits. A questionnaire for patients exploring perceptions regarding MAT will be conducted as well. A re-audit will be performed 6months from starting date. With increased awareness, MAT will become standard of care at the Detroit VA.

No. 131

Black and White Bugs: A Case of Delusional Parasitosis

Poster Presenter: Jillian Porter Larsen, M.D., M.P.H.
Co-Author: Kelin M. Ogburn, M.D.

SUMMARY:

Mrs. E, a 58 y.o. Hispanic female with no previous psychiatric history, presents to the Emergency Department complaining of black and white bugs crawling on her skin. Past medical history was significant for cardiovascular accident (CVA) 8 years prior (left MCA-PCA territory) with some residual right-sided weakness, hypertension, and diabetes. Patient reports she has felt the bugs crawling on her skin for the past 1-2 weeks and during evaluation, she picks on her skin to show them. She has multiple small wounds to her bilateral hands and lower extremities that appear consistent with skin picking and showed no signs of infection. Patient reports occasional social drinking and denies any recent recreational drug use, though she does endorse a remote history of cocaine use. Patient's husband reports that he has never seen one of these black and white bugs and denies substance use by wife. Patient's presentation of delusional parasitosis had a broad differential diagnosis, including schizophrenia of late onset, delusional disorder, psychosis secondary to a general medical condition [CVA], obsessive-compulsive disorder, and substance induced psychotic disorder. Mrs. E was admitted to inpatient psychiatry and started on an antipsychotic at a low dose (risperidone 0.5mg) due to patient's age and history of CVA as well as diphenhydramine for pruritus. Patient's urine drug screen returned positive for amphetamines, cocaine, and opiates. Further collateral from patient's oldest daughter revealed history of methamphetamine use in the family home and that her younger daughter was recently jailed for drug-related offenses. Patient then finally admitted to recent use of cocaine. Patient responded well to risperidone and reported she did not see any bugs on her skin throughout her admission. The final diagnosis was substance-induced psychotic disorder. Patient's prior medical history of CVA, female gender and older age made the diagnosis of substance-induced psychotic disorder less evident. Despite the swift resolution of this case, admission was warranted for diagnostic clarification safety concerns. Due to the severity of her delusional thinking, patient was at risk of self-harm by skin excoriation, overdosing on medications like antihistaminics to treat the pruritus, or applying of chemicals to her skin to eliminate the perceived infestation. This case serves as a good reminder that substance use can affect any person of any gender, age, or prior medical history and the importance of

timely urine drug screens in patients presenting with psychosis.

No. 132

Expanding the Role of Psychiatrist in Difficult Cases of Psychosis With Underlying Medical Conditions

Poster Presenter: Komaldeep Gill
Lead Author: Gagan Deep Mall, M.D.
Co-Author: Amardeep Sahota

SUMMARY:
Current literature lacks robust evidence which addresses the role of psychiatrist in diagnosing disabling medical conditions such as Huntington's Disease (HD) where, in most cases, psychiatric symptoms present several years prior to onset of chorea. Although affective disorders and OCD are more commonly present, still psychosis is seen between 3 to 11 percent of cases. Many studies show no correlation of psychiatric symptoms with duration of disease, repeat length, or presence of dementia or motor symptoms; therefore, diagnosis is delayed in such cases. To emphasize this, we report an interesting case of a 57 year-old patient admitted in a forensic psychiatric treatment facility presenting with psychosis and paranoia who developed intermittent movement disorder later. On admission physical examination, no involuntary movements were noted. No improvement in this movement disorder which was possibly considered an extra-pyramidal symptom (EPS) was seen on switch from Olanzapine to Quetiapine. As the patient's psychosis improved, he gave a history of similar involuntary movements in his mother. HD was considered in the differential diagnosis of psychosis with chorea and genetic testing confirmed the diagnosis of HD. There are no clear guidelines to differentiate psychosis caused by psychiatric disorder or psychosis occurring as a pre-clinical manifestation of an underlying medical condition like HD. More studies are needed to help differentiate between these two diagnoses as psychiatrists may play the role of a primary care physician for patients presenting with psychiatric illness secondary to a medical disorder.

No. 133

Salt Into Wounds: A Case Report on Hypernatremia-Related Agitation in a Patient With Traumatic Brain Injury (TBI)

Poster Presenter: Salima Jiwani, M.D.
Co-Authors: Alison Dempsey, Sanjay Yadav, M.D.

SUMMARY:
Hypernatremia is a potentially life-threatening medical emergency, defined as serum sodium concentration >145 mEq/L. Signs and symptoms include muscle cramps, seizures, headaches, intracranial hemorrhage, lethargy, coma, and death. Gradual correction of hypernatremia prevents cerebral edema and serious neurologic complications. Patient is a 28 year old female, with a history of mitral valve stenosis and double outlet right ventricle. She has a psychiatric diagnoses of Bipolar Disorder, ADHD, and substance use disorder including cocaine, hallucinogens, MDMA, cannabis, and tobacco. Patient was admitted eight months ago to the hospital following a motor vehicle accident resulting in a severe brain injury. Injuries sustained included right parietal subarachnoid hemorrhage, bilateral intraparenchymal hemorrhage, multiple facial fractures, liver and spleen lacerations. Following a two week admission, she was discharged to a rehabilitation center. Patient was readmitted two weeks later from the rehab center with hypernatremia and dehydration. Patient was found to have panhypopituitarism and central diabetes insipidus following which she was started on desmopressin. Patient was transferred back to the rehab facility and over a period of two months she was progressing well. She then started exhibiting mild agitation which gradually progressed to "behavioral issues." She underwent multiple trials of medications to manage agitation following which she started experiencing increased sedation, tachycardia and diaphoresis, which led to another hospital admission fearing neuroleptic malignant syndrome but we found her to have developed dystonia. The patient had been refusing medications including desmopressin and free water boluses. Patient's labs were notable for hypernatremia for the majority of the six week long hospital admission. Her sodium levels were in the range of 128-163 (more than eight instances of sodium greater than 155). Throughout her stay, patient had multiple episodes of being agitated, verbally abusive, and combative, which often led her to being put in four-point restraints. She also had periods of extreme

restlessness during which she would walk along the hospital hallways and corridors. It was noted that patient was more agitated when her sodium levels were elevated. While this patients location of brain injuries may explain her disinhibition and agitation, an emerging correlation between aggression and elevated sodium levels should be noted. With this correlation in mind, patients presenting with TBI-related hypernatremia need to be monitored closely for changes in behavior and sudden fluctuations in sodium levels. Compliance with treatment is of utmost importance in patients with such a complex constellation of symptoms. In addition, we should be aware of a wide array of electrolyte imbalances associated with TBI, not just hyponatremia- the most common presentation. In this case, the opposite presents, with lasting effects.

No. 134

Foxtrot or Jitterbug: Still Dancing With Delirium

Poster Presenter: Salima Jiwani, M.D.
Co-Authors: Sean Nutting, Aum A. Pathare, M.D., Maryam Zulfiqar, M.D.

SUMMARY:

Autoimmune encephalitis has a variable presentation; understanding this is critical for prompt identification and management. A 71 year old female with hypothyroidism, diabetes mellitus type 2, major depressive disorder and generalized anxiety disorder presented with four days of worsening choreiform movements in all extremities. She awoke with a tongue ulcer, progressing to multiple oral ulcers. She then developed mild involuntary movements, after which she visited her PCP who attributed the symptoms to worsening depression, and increased her escitalopram dose of 3 years from 30 mg to 40 mg daily. She then presented to the emergency department and was given a diagnosis of oral thrush and discharged home. She later developed periorbital edema and a nonpruritic, non-painful rash on the extensor surfaces of her arms and face. The following day, she returned to the ED and was transferred to our facility; escitalopram was discontinued. She was found to have elevated AST and ALT, inflammatory markers, and Coxsackie a4 and B1 antibody titers. CT scan revealed focal hypodensity at the inferior basal ganglia which led to an MRI, revealing punctate acute infarcts in the bilateral putamen and an early subacute left posterior putamen infarct. Neurology suspected small-vessel, cardioembolic, or vasculitic etiologies. Dermatology performed a biopsy of the rash, results were nonspecific. Her movements were rapid, large-amplitude, asynchronous, more distal than proximal, choreiform, and terminated with sleep. Lorazepam was given for worsening movements but they exacerbated over the next three days. She became agitated, combative, and confused; quetiapine and haloperidol were used. Given the risk of worsening movement disorder with neuroleptics, dexmedetomidine was preferred, but proved ineffective. She was then sedated with propofol and fentanyl and intubated. Methylprednisolone 1000 mg IV q24h was initiated and the movements ceased. A CSF analysis following a lumbar puncture was unremarkable. An EEG performed during sedation demonstrated diffuse background slowing and sharp transients in the frontal region. The patient was weaned off sedation and extubated, but remained delirious. Her purposeless movements in all four extremities were less severe and distinct from her prior movements. Mentation and involuntary movements gradually improved. She was transitioned from IV steroids to oral prednisone 60 mg daily. During hospitalization, multiple specialties gave multiple diagnoses: SSRI discontinuation syndrome, akathisia and vitamin deficiency. The presentation of delirium concurrent with ballistic movements is an uncommon manifestation. Given the rarity and complexity of autoimmune encephalitis, a high degree of suspicion to provide early treatment, evidenced by her quick response to steroids, was required. This erratic presentation should prompt psychiatrists to suspect an autoimmune etiology for similar clinical pictures to initiate treatment.

Pica: Discussion of a Unique Presentation to a Crisis Service, Underlying Causes, and Management Strategies

Poster Presenter: Sarah Miller, M.D.
Co-Authors: Amanda Jane Gavin, M.D., Emily Maguire, M.D., James Jefferson Graham, D.O., Jessica Graham Kovach, M.D.

SUMMARY:

Ms. J is a 62 yo F with past medical history of CHF, End Stage renal disease, hepatitis C, diabetes, dyslipidemia, and hypertension who was brought in by her daughter after ingesting a month's worth of medications. While the emergency room physician reported this was an intentional overdose, the patient denied ever having suicidal ideation and said life was worth living for her grandchildren. She reported craving dirt, was physically unable to obtain dirt, and therefore decided to eat her medication. Ms. J reported that she had been eating 1-2 tablespoons of dirt her "entire life" at least once per week. "My father taught us (pt and 7 siblings) to eat dirt. . . not because we were hungry, it's just what we did in Virginia. " At times during her adult life she tried to substitute oats, flour, and other more acceptable food substances but found that these did not satisfy her cravings and did not give her the same relief that eating dirt did. She recognized that this behavior was unusual and chose not to reveal it to her physicians or her family. Social history was significant for being raised by an alcoholic father and multiple episodes of sexual trauma by her siblings as a child and as an adult. She raised 3 children on her own and held various jobs as a mechanic until she developed renal failure one year ago. Determining the underlying causes of this patient's pica was complicated by anemia of chronic disease, multiple medical problems, depressive symptoms in response to the stress of her medical illness, severe trauma history, chronic non-distressing voice hearing, and cultural and family acceptance and encouragement of pica behavior. Discussion of best treatment practices for pica is currently lacking in the psychiatric literature. In this poster we discuss the importance of awareness of the possibility of pica in patients presenting to a psychiatrist and the challenges of determining the causes of and best management of pica.

Fycompa (Perampanel) Worsening Aggression in a Patient With Lennox Gastaut Syndrome: A Case Report and Review of Current Literature

Poster Presenter: Sasidhar Gunturu, M.D.
Lead Author: Jagteshwar Sandhu
Co-Author: Suzanne Lippman

SUMMARY:

Lennox Gastaut syndrome (LGS) is a severe, disabling childhood epileptic encephalopathy that affects 3-10% of all those with epilepsy. Patients with LGS may exhibit resistance to treatment with most first line anti-epileptic drugs (AEDS). There has been increasing evidence of co-existing psychiatric and cognitive deficits in LGS patients. Interestingly, over the last decade there has been increasing evidence that newly launched AEDS may show increase propensity to induce or worsen a wide range of psychiatric symptoms and thus should be used with caution and close monitoring. In this poster we review the history of a young Hispanic male with a past medical history of LGS with intractable epilepsy, neurocognitive impairment, left frontal lobectomy, and a past psychiatric history of OCD. He was admitted to the hospital for altered mental status, increased aggression, and onset of homicidal and suicidal ideation reportedly following initiation of treatment with Fycompa. Fycompa is a medication indicated for the treatment of refractory epilepsy and it's unique in its class. It acts as a noncompetitive antagonist of the AMPA glutamate receptor in the central nervous system. There is an increasing amount of evidence that link Fycompa with the occurrence of psychiatric symptoms. Thus we discuss the pharmacology and review the current literature on Fycompa. This review may offer aid to clinicians while treating patients with Fycompa.

No. 137

Evaluating the Effectiveness of Brief Psychotherapy for Oncology Patients

Poster Presenter: Seth Gabriel Rosenblatt, M.D.

SUMMARY:

This poster will present preliminary findings from a recent research study conducted at the George Washington University Medical Faculty Associates Department of Psychiatry. Psychological distress and morbidity (including loneliness, anxiety, depression and PTSD) may be triggered or exacerbated by cancer diagnosis (Swartzman, et al 2016). Depressed cancer patients show worse treatment adherence and worse survival compared with non-depressed cancer patients (Hartubf et al, 2017). Cancer survivors in the United States reported using medication for depression and anxiety at twice the rate of the general public (Hawkins et al 2017).

Childhood cancer survivors may experience post-traumatic stress symptoms as young adults or adults. Psychiatrists and resident trainees are not normally trained to deal with special needs of cancer population, and this training takes place within the GW psychooncology clinic. Given the high prevalence of mood disorders and adjustment disorders among oncology patients, this study will aim to assess if our current intervention is beneficial in addressing the client's target symptoms. The study will examine the effectiveness of brief psychotherapy for oncology patients. Currently, patients are referred to the psychooncology clinic from various oncologists and social workers with the oncology center. Resident psychiatrists provide 5-8 sessions of brief psychotherapy to address issues of anxiety, mood changes and adjustment to diagnosis. This study aims to examine if therapy sessions achieve the goal of helping to decrease anxiety and mood changes and changes patient's outlook on life. Patients will be administered surveys assessing for depression, anxiety and well-being prior to and following therapy sessions and the results will be compared. The hypothesis is that patients will score significantly lower on the anxiety (GAD-7) and depression (PHQ-9) questionnaires and higher on the WHO 5 measure Quality of Life Scale, indicating that the several sessions of brief psychotherapy were effective in helping them to develop positive coping skills to adjust to their diagnosis and how it impacts their lives.

No. 138

Influence of Psychiatric Comorbidities in Hospital Readmission Rates in Patients With Chronic Obstructive Pulmonary Disease

Poster Presenter: Shehryar Khan, M.D.

SUMMARY:

Introduction: Hospital readmissions contribute as a significant factor in high healthcare costs. Chronic Obstructive Pulmonary Disease (COPD) is the third leading cause of death, and patients with COPD have 30 day readmission rate of 19.6%. Patients with COPD have high comorbidity with depression, anxiety and cognitive impairment (CI). The objective of this cross sectional study was to determine if underlying psychiatric comorbidities influence the readmission rates. There was an additional intervention arm, but data analyses is incomplete at this time and only results from the cross-section study are presented as below. Methods: Newly admitted COPD patients (n= 107) were evaluated for demographic, clinical and putative risk factors by reviewing charts, conducting interviews and administering Mini-Cog and Hospital Anxiety and Depression Scale. Baseline data against number of past 12-month admissions were examined, and were tabulated from Electronic Medical Record. Covariation of risk factors and number of past year admissions were tested using univariate tests (Pearson Product-Moment Correlation Coefficients & Student's T-test). Results: Statistically significant results for higher admission rates were observed for history of Arterial PO2 < 40 (p=0.02), preadmission oxygen use (p=0.027), a prior hospitalization within the last 30 days (p=0.04), abnormal Head CT reading (p=0.08), number of comorbid conditions (p=0.03). Current marital status of being married was a statistically significant protective factor against number of hospitalizations (p=0.05). Statistically non-significant results were observed for anxiety, depression, age, sex, years of education, ethnicity, living circumstances, BUN, ammonia, arterial PCO2, FEV1/FVC severity, positive toxicology Screen, active smoking, recorded memory difficulties in-hospital or by family report, history of substance use, history of psychiatric hospitalization/psychiatric care/psychotropic medication use, items from the Mini-Cog, pack-years of smoking. Conclusion: Two predictors of number of admissions (Hx of a positive head scan & Hx of severe hypoxemia) are consistent with the hypothesis that CI increased likelihood of readmission, and that family support/compensation (marital status) decreases readmissions. The failure of the items from the Mini-Cog to reach significance is puzzling, requiring further investigation. Illness severity and complexity (number of comorbid conditions and oxygen use) also covaried with number of past year admissions. The failure of multiple medical factors commonly assumed to increase readmission risk (e.g., active smoking, FEV1/FVC, Age) is interesting and suggests that CI may be a far more potent cause of readmissions.

No. 139

Culture and Grief: The Confluence of Physical and Emotional Pain

Poster Presenter: Shelley Co, D.O.

SUMMARY:
Introduction: Grief is defined as a reaction to a loss, which involves the deprivation of something or someone. Bereavement refers to the state or period after a loss while the term mourning can be used to describe the external expression of grief. Certain cultures like those based in South America and Asia tend to somatize and so it is perceived as more culturally accepted to seek help for physical ailments rather than emotional ones. A complex situation then arises when a loss occurs to an individual with certain cultural expectations with regards to the expression of emotions. Case: Patient is a 54 year old Hispanic male with a significant medical/surgical history of liver transplant (nine months ago) as a result of Hepatitis C cirrhosis who initially presented with right sided abdominal pain. The patient was admitted to the surgical service due to concern for appendicitis. During this hospitalization, the patient had an unremarkable CT of the abdomen and pelvis and an unrevealing colonoscopy and no etiology of the pain could be identified. Patient about one week prior to this hospitalization reported that his wife of more than thirty-five years had died and so psychiatry was consulted to evaluate for a possible somatic symptom disorder. Upon talking about his wife to the psychiatry team, patient began to weep uncontrollably and endorse hopelessness, helplessness as well as suicidal thoughts; he also kept repeating that he was in pain and wanted to know what medications were going to be given to address his pain although there was no medical reason for this pain. This patient was eventually admitted to the psychiatric unit. Discussion: In some cultures, patients are more willing to discuss physical rather than emotional pain. Often times, these patients are dismissed once the work-up of the initial presenting complaint, that being a physical one, is done and no medical etiology can be found. However, it is important to recognize that the "pain" is real even if actually psychologically rooted and to maintain cultural sensitivity as a way to appropriately detect and manage emotional distress and mental illness.

No. 140
Catatonia Secondary to Hashimoto's Encephalopathy

Poster Presenter: Shivani Kumar, M.D.
Lead Author: Caroline Meehan
Co-Authors: Joseph J. Cooper, M.D., Holly Shiao

SUMMARY:
Catatonia is a neuropsychiatric syndrome with marked motoric findings which can be related to a psychiatric disorder or a general medical condition, such as Hashimoto's encephalopathy (HE). HE is a rare and poorly understood autoimmune syndrome, with an estimated prevalence of 2.1/100,000, characterized by rapidly progressive altered consciousness, seizures, and myoclonus (Ref 1). Other forms of autoimmune encephalitis are known to present with catatonia (Ref 2), including a few reports associated with HE (Ref 3-5). A woman in her 80s, with a psychiatric history of depression, was admitted for altered mental status. The family reported 2-3 weeks of progressive disorientation, agitation, paranoia, and echolalia. She was brought to the hospital where she became unresponsive, while maintaining an odd, "stiffened" posture. She was treated for suspected infection (WBC 20.1), hyponatremia (Na 119), and hypercalcemia. Her mental status failed to improve and she continued to have mutism, echolalia, and stereotypies. Infectious etiologies were excluded and paraneoplastic encephalitis panel was negative. Further workup revealed elevated ANA (320), anti-double stranded DNA (80), anti-TPO (440), and antithyroglobulin (1860), concerning for an autoimmune process. Imaging revealed right temporal/occipital/parietal and right posterior thalamic hyper-intensities concerning for encephalitis or prion disease. CSF was positive for 14-3-3 and t-tau (>4000) but the prion-specific RT-QuIC was negative, indicative of neuronal destruction without a specific etiology. Her stay was also complicated by intermittent seizure activity, urinary tract infection, and poor oral intake. Given high suspicion for autoimmune encephalitis, the patient was treated with steroids with partial improvement. At this time, her motoric symptoms were recognized as possibly catatonic, and psychiatry was consulted on Hospital Day 15 for catatonia. On exam, she had a Bush-Francis Catatonia Rating Scale (BFS) (Ref 6) of 31 with immobility, mutism, posturing, grimacing, stereotypy, waxy flexibility, withdrawal, rigidity,

automatic obedience, and gegenhalten. Intravenous lorazepam was started and BFS scores showed progressing improvement: 24 on Day 16; 12 on Day 19. Given anti-thyroid titers with otherwise negative workup, patient was diagnosed with HE. She was given a second steroid trial on Day 21, this time with concurrent intravenous lorazepam continued, which resulted in further improvements of her BFS to 7 on Day 21, and 4 on Day 22. Our case of HE showed rapid neuropsychiatric deterioration with seizures and severe catatonia. Treatment with lorazepam resulted in a robust response, consistent with data that catatonic symptoms respond to lorazepam regardless of the underlying condition driving the catatonia (Ref 7). Catatonia treatment should involve both treatment of the underlying disorder and concurrent symptomatic catatonia treatments such as lorazepam.

No. 141

Steroid-Induced Mania: A Case Report and Brief Literature Review About the Treatment and Prophylaxis

Poster Presenter: Suneela Cherlopalle, M.D.
Co-Author: Manasa Enja, M.B.B.S.

SUMMARY:
Corticosteroids are a widely used and highly effective treatment for a number of medical conditions, including immunologic and in?ammatory disorders, systemic lupus erythematosus (SLE) and systemic vasculitis, asthma and chronic obstructive pulmonary disease, cancer, acute and chronic back pain, and in the prevention of postoperative swelling in head and neck surgery. Unfortunately, while the medical side effects are well laid down, the neuro-psychiatric complications of the steroid use are not very well described. They range from delirium, depression, mania, mixed types and psychosis. Limited literature is available on the treatment options of the given conditions. This poster is to discuss the presentation of the steroid induced mania review of the treatment options for the steroid induced mania and also discuss the role of using prophylactic agents like Lithium and carbamazepine. Methods: We report a case where the patient presented with manic features after initiating dexamethasone 16 mg for her post chemotherapy nausea, improvement of appetite. She was treated with steroid taper and also with olanzapine antipsychotic. Patient was followed on an outpatient basis to see the improvement. Results: Patient's symptoms resolved after being treated with the low dose Olanzapine for 6 weeks. Discussion: With increasing use of corticosteroids in medicine there is higher occurrence of neuropsychiatric symptoms. Though the pathophysiology is not well understood, but clinical practice may bene?t from greater awareness of these potential adverse events and of methods to possibly prevent and treat them. In a 5 week open label trial Olanzapine at a dosage of 8.5 mg /day has been able to treat 11 out of 12 patients with steroid induced mania. A case series of 20 patients, treated with sodium valproate at a dosage of 500 mg BID has shown rapid reversal of mania in 48 hours. Isolated case report indicate resolution of symptoms with seroquel. Lithium has been indicated as a prophylactic agent in hypoalbuminemia, blood brain barrier damage and dose more than 40 mg of prednisone per day. Conclusions: Antipsychotics and mood stabilizers are currently used in the treatment and prophylaxis of steroid induced mania

No. 142

Evidence for Using rTMS Among Older Adults With Psychiatric Disorders: A Systematic Review

Poster Presenter: Suneela Cherlopalle, M.D.
Co-Authors: Arjun Nanda, Rajesh R. Tampi, M.D., M.S., Kirsten D. Wilkins, M.D., Geetha Manikkara

SUMMARY:
OBJECTIVES: The aim of this systematic review is to identify published randomized control trials (RCTs) that evaluated the use of repetitive transcranial magnetic stimulation (rTMS) for psychiatric disorders among older adults. METHODS: A literature search was conducted of PubMed, MEDLINE, OVID and PsychINFO databases for randomized controlled trials (RCTs) in any language that evaluated the use of rTMS for various psychiatric disorders among adults were searched through September 30, 2016. Only studies that were published in English language journals or had an official English translation were included in the final analysis. Additionally, bibliographic databases of published articles were searched for additional studies. RESULTS: A total of 40 RCTs were obtained through the search

strategies. Conditions studied (n=number of RCTs) included mild cognitive impairment (MCI) (n=1), Alzheimer's disease (n=4), major depressive disorder (n=14), schizophrenia (n=5), treatment resistant depression (n=4), geriatric depression (n=2), bipolar depression (n=2), depression in Parkinson's disease (n=1), vascular depression (n=1), nicotine dependence (n=1), cocaine addiction (n=1), motor cortical function (n=2) and pain perception (n=1). Available data indicate that in the majority of the studies rTMS was well tolerated, but efficacy results were variable with some studies showing benefit whereas other studies showed limited efficacy. CONCLUSIONS: Although limited, available evidence suggests that rTMS is a safe and effective procedure. Side effects associated with its use include mild insomnia, transient headache, transient scalp tenderness, hearing problems that spontaneously resolve, transient difficulty concentrating, and worsening depression without need for any specific intervention in the majority of cases. rTMS may benefit various aspects of Alzheimer's disease including an improvement in attention and psychomotor speed with sustained effects lasting for 3 months.1 Its use in individuals with schizophrenia did not appear to show significant benefit as in 3 trials there was no difference in refractory auditory hallucinations.2 However, there was improvement in negative symptoms in two trials.2 The majority of the studies of rTMS in depressive disorders showed no significant clinical benefit but some symptoms, like psychomotor retardation, did improve. In treatment resistant depression, only one of the four studies showed benefit with greater remission rates in the group that used rTMS. No significant benefit was noted among the trials involving individuals with bipolar depression and geriatric depression. Greater chance of abstinence was found among older individuals with cocaine dependence and nicotine dependence who received treatment with rTMS.3,4 These results indicate that rTMS may be beneficial for certain psychiatric disorders in older adults but the risks and benefits of its use should be carefully assessed before embarking upon treatment .5

No. 143

Medical Students' Attitudes Toward Torture, Revisited

Poster Presenter: Andrew Milewski

Co-Authors: Krista Dubin, Thomas Peter Kalman, M.D., Joseph Shin, M.D.

SUMMARY:

Background: While medical organizations worldwide have unambiguously condemned physician involvement in torture, historically, state-supported torture programs have always included participation by medical professionals. We report findings of a survey of medical students' attitudes towards torture and discuss variables that may correlate with those attitudes. Methods: 483 enrolled medical and MD-PhD students at the Weill Cornell Medical College received an anonymous, IRB-approved survey that included demographic items, questions about torture and its effectiveness, inquiries about personal experiences of harassment or discrimination, and items regarding engagement in human rights activities. Some items were drawn from a 2008 University of Illinois College of Medicine study of medical student attitudes towards torture, the only prior such survey. Ordinal regression and correlation analyses were employed to ascertain relationships between participant responses. Results: 121 participants (25% response rate) returned completed questionnaires, with more than 90% of responses indicating strong opposition to torture and skepticism about its usefulness. Interestingly, students were most opposed (97.5%) to interrogators employing tactics that would cause physical distress or injury. Those who believed that torture is immoral also supported prohibiting torture as a matter of state policy. The majority of responses also favored disciplinary or legal action for health professionals who were found to have designed, committed, or otherwise facilitated acts of torture. A number of demographic factors, including age, gender, sexual orientation, ethnicity, and religion, were not found to bear on respondents' attitudes towards torture. Individuals who had personally experienced harassment or had a family member with such a history were less opposed to torture than those with no such experiences; however, this trend did not reach statistical significance. Participants were more opposed to torture compared to respondents of the 2008 survey. Voluntary engagement in Weill Cornell's human rights program was associated with significantly stronger opposition to torture. Conclusion: Although

demographic factors were found to be noncontributory, a statistically significant correlation was seen between students' participation in the human rights program and their attitudes towards torture. The sizable difference in students' opposition to torture between the present and 2008 studies may be related to the absence of a human rights program for University of Illinois students at the time of their survey. Other factors may include the extensive coverage of intervening human rights disasters, such as those in Syria, and a generally increased awareness of all human rights abuses, including but not limited to torture.

No. 144

Mindfulness Training in the GME Setting: Ways and Means to a Mindful Resident

Poster Presenter: Andrew Charles Martina, M.D., M.A.
Co-Author: Vineeth John, M.D., M.B.A.

SUMMARY:
Mindfulness has been recognized as a potential asset with regard to enhancing resident trainee well-being and resiliency. Mindfulness involves "cultivating our ability to pay attention in the present moment as we suspend our judging." Currently, there is scant literature describing real world examples where mindfulness practices have been integrated with residency training. This poster intends to highlight the attributes of studied modalities for mindful trainings in residency, as well as the challenges to their implementation within the framework of residency education. There are multiple documented approaches to delivering the basic tenets of mindfulness ranging from large, extended courses to brief cellphone based guided meditations. Mindfulness based stress reduction courses and their video counterparts have the benefits of providing a robust introduction to common mindful techniques and ongoing opportunities to understand and implement skills over a longer period of time. These courses are generally offered on a varied schedule, lasting 6-8 weeks, usually outside the workplace in a retreat style environment. This approach necessitates a higher cost for their implementation as well. While retreats may provide a longer lasting or more robust response, they are often impractical given the prohibitive demands of both their expense and time commitments. Shorter classroom based interventions allow residents to attend a brief series of presentations designed to deliver high yield mindfulness techniques along with opportunities to demonstrate these skills. Classroom courses lend themselves to easier integration into resident didactics and clinical schedules at a reduced cost burden to programs. However, limited evaluation of this approach indicates it may only benefit a small subset of residents in particular settings and may not lead to short-term improvements in the self reporting of burnout. Two studies to date have assessed the feasibility of a smartphone based intervention, increasing the accessibility and usability of a mindfulness practice for residents at a manageable cost with the capacity to still provide some benefit. At this stage, the research of mindfulness training in residency is generally under powered, relying heavily on self reporting, is often unblinded and without a control population. When integrated into resident education, mindfulness training has the potential to provide the support and stress reducing resiliency augmentation residents greatly need. With appropriate attention paid to program culture and trainee routines, residents can work with their residency administration to pinpoint the what, when, and how of efficiently integrating mindful practice into their education.

No. 145

Finding Calm Before the Storm: A Hurricane Preparedness Model

Poster Presenter: Durim Bozhdaraj, M.D.
Co-Authors: Monica Lynn Vega, M.D., Ashley Beattie, M.D.

SUMMARY:
Hurricane Season runs from June 1st to November 30th and, here in South Florida, hurricane preparedness is an important topic. This year, the psychiatry department at Jackson memorial Hospital in Miami, Florida has worked with faculty and residents to develop a preparedness plan to help prepare residents and faculty in the event of a hurricane. While this is not a new plan, it is important to remember that keeping faculty and staff up to date on the basics of hurricane preparedness may prevent some confusion when it

is time to implement these action plans. For the hurricane preparedness plan there are several factors to consider; coverage, relief, safety, and supplies. The plan needs to ensure that each department has an adequate number of staff available to provide care for the patients in the hospital during a storm. A relief team of staff volunteers that are located on site and are available to take over for the primary team should be identified in case environmental factors prevent others from entering or leaving the hospital for some time. The hospital environment needs to be safe for all patients and staff throughout the storm. Supply stores for food, water, and medications should be monitored. Hurricane season can be a very stressful time for many. While preparing for every possible outcome of a hurricane is impossible, keeping residents and staff as prepared as possible and helping them to create their own safety plans can help to reduce some of the stress felt throughout the hurricane season.

No. 146

Warranting Well-Being? The Accreditation of Psychiatry Training Programs in Australia and New Zealand

Poster Presenter: Diana McKay, M.B.B.S.
Co-Authors: Amro El Sholkami, David C. Furrows, M.D., Gagan Garg, Michelle Atchison

SUMMARY:

Background: The Royal Australian and New Zealand College of Psychiatrists (RANZCP), through its Accreditation and Education Committees, defines standards for the accreditation of psychiatry training programs in Australia and New Zealand. Linked with these standards are five-yearly site visits, which aim to review and accredit programs against these standards in a robust and transparent way, noting both areas of commendation and recommendations for improvement. Site visitors include two psychiatrists, a trainee (psychiatry resident) and RANZCP administrative secretariat. In light of growing international and local awareness of concerns over burnout and depression in residency years, the Accreditation Committee recently reviewed existing Accreditation Standards to focus more clearly on wellbeing1,2. This reflects a growing interest within the RANZCP to promote wellbeing for psychiatrists in training, as well as for qualified psychiatrists. This is in line with moves in other countries, such as the USA, highlighting the need for training accreditation to more explicitly consider wellbeing 3. Objective: Program Accreditation Standards cover five governance, clinical and educational domains. The changes made to Program Accreditation Standards in light of wellbeing considerations will be explored, including areas of ongoing review and development. Resident workload in acute adult inpatient psychiatry terms has also been an area of interest to the Committee, noting the potential for conflict between training and service provision when workload is excessive. Other changes made to accreditation programs include ways to maximise the trainee voice and engagement in the accreditation cycle, with the addition of a trainee pre-accreditation visit survey to identify areas of concern, the circulation of an accreditation report summary to trainees and the trial of a mid-cycle review process. Psychiatry trainees (residents) are also represented on the Accreditation Committee itself, in line with RANZCP practice for many College committees. Conclusion: These accreditation changes will be compared with training accreditation standards the USA and Canada, given this is an international area of concern.

No. 147

Practices Regarding Use of Metformin for Antipsychotic-Associated Weight Gain

Poster Presenter: Emily Louise Ottiniano, D.O.

SUMMARY:

Background: Weight gain associated with antipsychotic use is a prevalent problem amongst psychiatric patients. The alterations occur in not just body weight and BMI but in metabolic measurements such as Hemoglobin A1C as well as lipids and can occur irrespective of weight gain. Although the medical literature recommends the use of metformin to prevent and treat antipsychotic-associated weight gain, providers infrequently follow this evidence-based recommendation. We are interested in assessing the prevalence of use of Metformin in psychiatric settings as well as if there are any concerns that outpatient psychiatrists have about using a medication such as Metformin in their

practice. Methods: Patients- Retrospective chart review of random sampling of 110 charts to determine the patients' diagnoses, medication regimens, and weight and BMI measurements. Providers- 11 PGY3 resident psychiatrists voluntarily completed a survey before and after receiving an educational handout about metformin use. Surveys were conducted one month apart. They were asked about current prescribing patterns, barriers to use, and preference for educational interventions. Results/Conclusions: Patients- Of those on an antipsychotic, metformin and who did not have comorbid Diabetes Mellitus, the male sample's weight and BMI were higher than those only on an antipsychotic and in the female sample, the weight and BMI was less than the female only on an antipsychotic. This result may be related to the typical patient demographic that is seen at the outpatient psychiatric clinic, those who tend to be chronically ill and on long-term antipsychotics. Providers- First survey: There was a wide range of responses to the proportion of how many patients were on an antipsychotic, on an antipsychotic with metabolic derangements. Majority (80%) started a patient on Metformin and 40% felt comfortable prescribing Metformin. Some of the reasons for not prescribing Metformin that were of note included: attendings not being comfortable with prescribing Metformin; not feeling that the data was compelling enough to outweigh the risk versus benefit; concerns about complicating an already complicated regimen along with concerns about patient adherence. Majority reported that an educational handout would be most helpful for comfort with prescribing Metformin. Second Survey: wide range of responses to number of patients eligible to start Metformin. 4 Residents started a patient on Metformin in the preceding month. The range for comfort in prescribing Metformin was wider and overall there was an increase in the comfort level with bimodal distribution of comfort level. 7 referrals made to outside providers for a prescription for Metformin. Majority found the educational information helpful and that it increased their comfort with Metformin.

No. 148

Comparing the Effectiveness of a Guide Booklet to Simulation-Based Training for the Management of Acute Agitation

Poster Presenter: J. Corey Andrew Williams, M.D., M.A.

SUMMARY:

Objective: The objective of this study was to compare the teaching effectiveness of a simulation-based training to reading a resident on-call psychiatry guide booklet in improving the self-confidence and knowledge of residents that is necessary for managing acutely agitated patients. Methods: Pre-intervention self-confidence and knowledge were measured for all residents using a Likert scale questionnaire and a clinical vignette questionnaire, respectively. Residents (n = 23) were randomly assigned to either the simulation group (n = 12) or the guide booklet group (n = 11). Residents in the simulation group completed the simulation-based training, and residents in the guide booklet group were instructed to read the corresponding pages of the booklet regarding management of acute agitation. The comparative teaching effectiveness of the guide booklet and simulation-based training were measured with a post-intervention self-confidence questionnaire and a clinical vignette questionnaire. Results: Residents who participated in the simulation-based training showed significantly greater improvement in self-confidence (simulation median improvement = 1.458 vs. guide median improvement = 0.033, p = 0.002) and knowledge (simulation median improvement = 0.135 vs. guide median improvement = 0.021, p = 0.0124) when compared to the guide booklet group. Conclusion: Simulation-based training was more effective at improving residents' self-confidence and knowledge compared to the on-call psychiatry booklet for the management of acutely agitated patients. Simulation-based learning is an underutilized teaching tool psychiatry, and this finding underscores the potential for utilizing simulation-based training in psychiatry residency programs to improve resident learning.

No. 149

Characterizing E-Cigarette Use in Smokers With Mental Illness

Poster Presenter: John Wang
Co-Authors: Amy Gravely, Erin Rogers, Scott Sherman

SUMMARY:

Background: Smokers with mental health conditions (MHC) are often more addicted to cigarettes and have greater difficulty quitting than those without MHC. Electronic cigarettes (e-cigs) have been suggested as tools to assist in quitting smoking, but their use in smokers with MHC is not well-characterized. We assessed e-cig use among smokers with MHC by investigating their reasons for use, readiness to quit smoking, and attributes of mental illness. Methods: We used baseline survey data from a large randomized smoking cessation trial enrolling smokers with a mental health visit in the past year. Veterans Health Administration (VA) EMR was used to identify participants from 4 national VA hospitals and to obtain data on psychiatric diagnoses. Former e-cig use was defined as having ever tried an e-cig. A contemplation ladder of 0-10 measured readiness to quit smoking. Pearson's Chi-Square and ANOVA Type 3 F-Tests were used to analyze findings. Results: Among 1836 participants, mean age was 58 years (STD11 years) and 87% were male. Top primary psychiatric diagnoses included substance use disorder (42% of subjects), depression (15%), PTSD (10%), other alcohol disorder (7%), and anxiety (6%). Participants smoked 15 cigarettes per day on average and 79% smoked within 30 minutes of waking. 15% of subjects were current e-cig users (n=275) and an additional 27% were former e-cig users (n=503). 65% of e-cig users reported "wanting to quit smoking" as a primary reason for e-cig use. A past smoking quit attempt was reported by 90% of current and former e-cig users and 82% of never-users (p<0.0001, OR=0.53, 95%CI=0.40-0.70). Mean readiness to quit smoking (0-10) was 7.2 (STD2.6), 6.8 (STD2.8), and 6.4 (STD3.0) for current, former, and never e-cig users respectively (p=0.0002). Mean confidence to successfully quit (0-10) was 5.4 (STD2.5) for all 3 groups. A longest quit attempt length of 1 week or less was reported by 50% of current and former e-cig users and 42% of never-users (p=0.01, OR=1.37, 95%CI=1.08-1.74). Mean number of psychiatric diagnoses was 1.9 (STD1.4) for current and former e-cig users and 1.6 (STD1.4) for never-users (p=0.0003). 63% of current and former e-cig users and 55% of never-users reported some mental distress on the Kessler-6 scale (p=0.0003, OR=0.73, 95%CI=0.60-0.88). A primary psychiatric diagnosis of alcohol or substance use disorder was recorded for 50% of current or former e-cig users and 60% of never-users (p=0.0003, OR=0.69, 95%CI=0.56-0.84). Conclusions: E-cig users were more ready to quit and reported a past quit attempt more often than non-users, possibly because they adopted e-cigs to assist with quitting. However, they were not any more confident in their success. Non e-cig users had less severe mental illness and were more likely to have alcohol or substance use disorder as their primary psychiatric diagnosis. Future research should investigate the smoking cessation success of e-cig users in mental health populations.

No. 150

Difficulty With Initiating ECT in a Patient With Catatonia

Poster Presenter: Kim Hoang, M.D.

SUMMARY:

Ms. S is a 30-year-old educated Asian American female formerly employed as a ticket operator who was admitted for the symptoms of isolating herself, poor hygiene and self-care, and screaming. She had 1 prior psychiatric hospitalizations two years prior in the context of worsening bizarre and isolative behavior, poor ADLs, and paranoia. The times when she did leave her house, she engaged in dangerous behaviors such as a climbing up a tree and sitting there or sitting near a freeway without clear intent of suicide. Patient did not believe she had a mental illness and refused medication. She remained selectively mute- speaking only to her social worker at select times, slowly paced the hallways from the time she awoke to the time she slept- up to 15 hours of a time. She would only interrupt her stereotyped pacing to sit down for a meal or go to sleep. She did not shower, often missed meals days in a row, and did not engage with any of the treatment team or others on the ward. Medical work-up was negative. Court order of medication was required and she was tried on several different antipsychotics including clozapine without improvement in her symptoms. Her affect remained flat, she exhibited extreme negativism, and showed stereotypy – if a person or object were in her way, patient would continue bumping into the person or object until it was removed. Family was involved and did not feel that they could overcome her oppositional attitudes. High doses of lorazepam IM were administered by

court order as she did not want medication with minimal improvement in her catatonic symptoms. Court ordered ECT was pursued with barriers to implementation as patient was oppositional and remained so. Patient could not cooperate with procedure or remain still. ECT and high doses of benzodiazepines are the treatment of choice in the treatment of catatonia. In this poster, we discuss the challenges of implementing ECT for the treatment of catatonia when other psychotropics and methods have been used in a patient who is oppositional.

No. 151

Cannabilistic Desire: Diagnosis and Treatment

Poster Presenter: Lisa Herrington, M.D.
Co-Author: Heather Kimberly Mak, M.D.

SUMMARY:
Self-mutilation can be a common feature in multiple psychiatric disorders, but urges to eat one's own flesh and the flesh of others is not. In this case, a 21-year-old male presented to the inpatient psychiatry ward after self-amputating his left small finger and ingesting it. He had a history of ego-syntonic desire to eat his own flesh and the flesh of others. He also reported auditory hallucinations that urged him to complete this action. Differential diagnosis of this patient was broad and included personality disorder, psychotic disorder, mood disorder, impulse control disorder, and paraphilia. His ego-syntonic desire and hallucinations persisted despite multiple trials of psychotropic medications, but a combination of an antipsychotic and an antidepressant inhibited him from acting on these urges. This case report explores the diagnostic and treatment dilemmas of managing a patient with cannibalistic desires and behaviors.

No. 152

Development and Implementation of a Residency Area of Distinction in Lesbian, Gay, Bisexual, and Transgender Mental Health

Poster Presenter: Matthew E. Hirschtritt, M.D., M.P.H.
Co-Authors: Weston Scott Fisher, M.D., Ellen Haller, M.D.

SUMMARY:
Background: Lesbian, gay, bisexual, and transgender (LGBT) individuals often encounter stigma, victimization, exclusion, and perceived discrimination, which are thought to contribute to the increased rates of mental health conditions within this marginalized group. In turn, perceived discrimination may reduce help-seeking behavior. Therefore, residency programs need to train future psychiatrists to recognize and address mental health issues in their LGBT patients. Here, we describe a novel "area-of-distinction" (AoD) in LGBT mental health within an adult psychiatric training program. Methods: Our large, university-based residency training program recently developed an LGBT psychiatry AoD that provides elective specialized training for residents interested in developing LGBT mental health expertise. Core organizers, who included both residents and faculty, reviewed the literature, discussed relevant clinical rotation opportunities, and developed ideas for how to convey LGBT-specific medical knowledge. Working-group members generated a list of topics and competencies and used a consensus-building process to organize these topics into three broad content categories: (1) LGBT minority stress, (2) medical and psychiatric issues specific to LGBT communities, and (3) identity and lifespan issues in LGBT individuals. In order to receive a certificate of AoD completion at graduation, participants are required to complete at least two LGBT-oriented clinical rotations, lead yearly peer-to-peer educational sessions, review the relevant knowledge base, regularly participate in individualized mentorship, and complete and disseminate a scholarly project that reaches an audience beyond the residency program (e.g., a poster presented at a professional meeting). Results: The program was launched in the 2013-14 academic year. Our residency program has 16 residents in each class; to date, the AoD has graduated 5 residents, and 6 residents are currently active in the AoD. Twelve faculty members, associated with 8 clinical rotations across 3 training sites volunteer their time as AoD mentors, and an additional 3 research faculty volunteer time to assist residents with their scholarly projects. Current and graduated AoD residents have cited clinically useful knowledge and skills that have strengthened their ability to work effectively with LGBT patients. Conclusion: The creation and launch of this LGBT Psychiatry AoD has led to 11 residents receiving specialized training so far. It has also

facilitated the creation of a warm and diverse community of individuals within our department committed to working with LGBT patients. We hope that this AoD's components may serve as a resource for training program leaders considering ways to integrate LGBT-specific education into their curricula.

No. 153

Auditory Hallucinations in Nonpsychotic Patients: A Sign of Disorder or Defense Mechanism

Poster Presenter: Meghan Elizabeth Quinn
Co-Authors: Janee Noel Mestrovich, D.O., Benjamin R. Hershey, M.D.

SUMMARY:

Background: Auditory hallucinations, the most common type of hallucinatory experience, have long been part of the diagnostic criteria for mental illness. However, research has shown that auditory hallucinations are not uncommon in individuals who are otherwise not psychotic. Prevalence varies by study, but estimates range from 1-10% of the pediatric population experiences some form of nonpsychotic hallucination at some point, with similar prevalence data reported in adult studies. There are different approaches to understanding the origin of these nonpsychotic hallucinations, ranging from analysis which sees them as a defense mechanism to modern behavioral approaches which struggle to place them in the framework of disease. Case: This patient is a 29 year old female with a past psychiatric history dating back to adolescence, where she describes promiscuity, alcohol and drug use, and mood lability beginning in high school and continuing on into adulthood. In adulthood she began to show borderline, obsessive compulsive, and anxious traits. There is evidence of some form of mental illness present in her brother and both parents, leading to a generally chaotic home environment for most of her childhood. At some point, the patient began experiencing auditory hallucinations, which have persisted into adulthood. These hallucinations are not command or persecutory, but rather comment on the patients surroundings in a way that relates to her anxieties and obsessions. Despite the presence of these hallucinations, the patient does not show signs of psychosis or disorganized thought patterns. She has the insight to appreciate that these hallucinations are not real. She presented to the emergency department and was subsequently admitted to the inpatient ward after an 8 month period of progressive decompensation following the deployment of her spouse. Whereas she had previously been able to largely ignore her hallucinations and continue about her daily life, she now reports that the hallucinations were intrusive and distressing and she was not able to ignore them. After inpatient stabilization, she was discharged to an intensive outpatient treatment program. Conclusion: Several psychoanalytic theories exist that promote auditory hallucinations as defense mechanisms in response to stress. Many of these theories suggest that hallucinations are protective against the development of future or worsened mental illness. While more traditional diagnostic criteria saw hallucinations as a sign of psychosis and mental illness, current research suggests that the phenomena is widespread among otherwise healthy individuals, giving credence to the theory that auditory hallucinations as a defense mechanism may be protective in individuals without other signs of mental illness. However, in individuals who present with signs of mental illness in addition to auditory hallucinations, these positive symptoms may be associated with worsened disease state.

No. 154

A Collaborative Approach to Mental Health Training for Internal Medicine Residents in the Ambulatory Setting

Poster Presenter: Nkemka Esiobu, M.D., M.P.H.

SUMMARY:

Primary care physicians are often the first to encounter undiagnosed/untreated mental health disorders and inadequately addressed mental health issues account for a significant amount of morbidity, mortality, and health care costs. However, internal medicine residents report low comfort levels with seeing patients with mental illnesses despite frequently encountering them in their primary care clinics. The aim of this project was to create a psychiatry resident led collaborative interdepartmental (Psychiatry and Internal Medicine) skills based workshop for internal medicine residents to address both attitudes

towards mental illness in primary care and gaps in primary mental health education through an innovative and interactive workshop. A survey assessing comfort with and attitudes towards primary mental healthcare was disseminated to 120 Yale New Haven Hospital Traditional Internal Medicine residents. Subsequently a 4 hour need based workshop was crafted focusing on 1) mental health stigma in health care 2) the impact of trauma across the lifespan and 3) substance use disorders in primary care. Quantitative and qualitative feedback from preliminary survey data and workshop discussion sessions was gathered. Results confirmed that residents exhibited minimal comfort with addressing mental health issues in their primary care rotations, many felt that mental illness affected the majority of their patient panels, and they desired more training and greater interdepartmental collaboration to better care for their patients.

No. 155

Chief Resident for Research in Psychiatry Residency Training

Poster Presenter: Stefana B. Morgan, M.D.
Co-Author: Victor Ivar Reus, M.D.

SUMMARY:

Co-Authors: Stefana Morgan, MD, Susan Voglmaier, MD, PhD, Victor Reus, MD, Erick Hung, MD, Jody K. Williams, MS, Michael Jacob, MD, PhD, Andrew Krystal, MD Background: Diversifying the chief resident model beyond the traditional clinical chief roles could enhance leadership opportunities for senior residents. Non-psychiatry residencies have introduced novel chief roles, such as the Chief Resident for Research (CRR), but few psychiatry prorgams have followed suit. Since 2015, the University of California San Francisco (UCSF) Department of Psychiatry has appointed three Chief Residents for Research. Role Description: PGY-4 residents in the UCSF Research Residency Training Program (RRTP) engage in ?75% research and devote the rest to clinical duties. PGY-4 RRTP residents can chose to apply to the RCC position, but RRTP operation is not chief-dependent. Notably, the RCC has a primary research project outside of RCC duties and to protect this focus, the RCC role is half of traditional chief roles, (only 10% of full time). 1) The main responsibility of the CRR is to improve research opportunities, visibility and outcomes for RRTP residents and non-RRTP residents engaged in research or scholarship projects. The CRR serves as a liaison between residents and RRTP leadership, provides near-peer mentoring and helps connect residents to research funding vehicles at UCSF and nationally. 2) The second role of the CRR is to assist with planning and implementing basic neuroscience and evidenced-based psychiatry education. Additionally, the CRR helps lead and improve RRTP events (i.e. resident recruitment days, departmental research day, bi-annual cutting edge science workshops, and California-wide psychiatry resident retreat). Informally, the CRR also provides guidance regarding the hidden curriculum of academic research – helps residents troubleshoot obstacles, advocates for balance between research and clinical obligations, and helps navigate relationships with mentors, peers and the department. Results: Of the three Chief Residents of Research at UCSF, two are male and the current one is female. Each resident customized the position to fit their interests while responding to program needs. The 2015-2016 chief focused on updating the neuroscience curriculum, and wrote a paper describing the California Research Resident Retreats. The 2016-2017 chief contributed to the innovative Neuroscience in the Media lecture series and improved the monthly Works in Progress dinners. The 2017-2018 chief is writing a paper reporting exploring motivations, outcomes and career trajectories for RRTP residents. She also updated the map of faculty study fields and projects, benchmarks for resident progression through the program, and sources of resident research funding. Conclusions: The chief resident of research role has the potential to provide research residents with leadership training opportunities and to improve the educational experience for all residents.

No. 156

Psychiatry Research Resident Training: Outcomes, Reflections and Pathways to Research

Poster Presenter: Stefana B. Morgan, M.D.
Co-Author: Victor Ivar Reus, M.D.

SUMMARY:

Co-Authors: Stefana Morgan, MD, Jody Williams, MS, Victor Reus, MD, Susan Voglmaier, MD, PhD, Andrew Krystal, MD Background: The shortage of well-

trained psychiatrists engaged in mental health research has increased over the last 20 years. One response to this alarming trend has been to bolster the educational pipeline for research psychiatrists with multiple interventions along the learning continuum starting in medical school or residency. One of these innovations is the Resident Research Training Program (RRTP) at the UCSF Department of Psychiatry, created in 2000. The program's development process, including its organizational structure, eligibility criteria for residents, and core program elements, have been described elsewhere along with 11 years of outcomes data (Tsai 2013). The current poster will present data that is a part of a larger study that aims to investigate the factors that motivate UCSF RRTP residents to continue to engage in mental health research after graduating from residency. It also aims to characterize the pathways, backgrounds, prior research experience, demographics, research outcomes, productivity and career trajectories of RRTP residents after graduation. This poster will focus on the data regarding RRTP resident outcomes. Methods: The study utilizes data on residents who participated in the RRTP, including newly collected data, publically available data and data that was already collected during RRTP enrollment, such as research project applications, resident demographics, research progress reports, etc. Quantitative data include personality traits, current positions and practice settings, percent of time devoted to research, support mechanisms in the post-residency transition, perceived barriers, perceived benefits to pursuing research and other motivating factors impacted participants' likelihood to pursue research careers. Results: The data, including past and current RRTP demographics, accomplishments, background and research interests as well as personality characteristics and qualitative findings regarding major themes of motivating factors will be presented in the poster at the APA in May 2018. Of the 74 residents who were enrolled in the RRTP between 2000 and 2017, 63 have already graduated. There is a general trend of an increased enrollment in the RRTP for UCSF residents over the last 5 years. Of the 63 graduates, 44 have continued to engage in clinical or basic research and have entered or completed clinical or research fellowships. Conclusions: Multiple factors influence the career development of research psychiatrists and understanding those factors can help increase the number of psychiatrists involved in mental health research. Interventions such as the UCSF RRTP can be instrumental in supporting psychiatrists to chose a career in research.

No. 157

Psychiatry Enrichment Programs: Evaluation of the Claassen Institute of Psychiatry for Medical Students

Poster Presenter: Zaza Lyons
Co-Author: Aleksandar Janca

SUMMARY:

Background: Psychiatry is an integral component of medical curricula around the world. Teaching and learning in psychiatry usually starts in the preclinical years and progresses to clinical clerkships. While attitudes towards psychiatry are reasonably positive, psychiatry as a career is regarded negatively by many medical students. Over the last ten years, in an attempt to improve recruitment there has been a growing interest in the development of psychiatry enrichment programs. These are extra-curricula programs specifically targeted towards students interested in learning more about psychiatry, both as a discipline and potential career pathway. The aim of this project was to evaluate the effectiveness of an innovative psychiatry enrichment program developed as a strategy to increase medical student interest in psychiatry as a career. It was hypothesised that student interest in a career in psychiatry would increase by the end of the program. Method: A novel enrichment program, the Claassen Institute of Psychiatry for Medical Students (the Institute) was developed at the University of Western Australia. The Institute was an intensive, week-long program that aimed to provide students with the opportunity to learn more about specialising and working in psychiatry. Interactive seminars covered diverse topics and current contemporary themes. Students also attended elective sessions at community and hospital-based mental health services. There was also a student led debate and interactive stigma discussion. Evaluation was conducted using questionnaires administered to students' pre and post program. Results: Between 2008 and 2015, 138 students (95 female, 43 male)

attended the Institute. Evaluation found that program attendance significantly increased student level of interest and knowledge in psychiatry. Numbers of students definitely considering a career in psychiatry rose from 77 pre-program to 106 post-program. Longitudinal evaluation found that approximately 20% of these were undertaking post graduate psychiatry training. Student comments included, 'This is the BEST program I've attended. Even though I was already initially interested in psychiatry, I am more motivated to do psychiatry as a career'; and 'Has helped me make up my mind that psychiatry is definitely for me'. Conclusion: Psychiatry enrichment programs are an emerging concept in medical schools that have the potential to improve the profile and image of psychiatry as a speciality to make it more attractive to medical students. The establishment of programs such as the Institute will enable psychiatry educators to act proactively to ensure that the psychiatric workforce remains sustainable in to the future. This was an unfunded study.

No. 158

The "On-Call Tracking Tool": The Process, Value, and Results of an Online Survey Designed to Examine Overnight Calls Taken by Psychiatry Residents

Poster Presenter: Jacqueline Posada, M.D.

SUMMARY:

Background: A cornerstone of residency is learning to assess a large volume and variety of patients, often in a less than optimal learning environment with stress, challenging clinical decisions, and sleep deprivation. Psychiatrists frequently remember their time on-call as integral to their development as autonomous physicians. In the GWU psychiatry residency program, one resident takes overnight call for the hospital managing acute issues on the psychiatric unit and responding to psychiatry consults from the emergency department (ED) and medical floors. Anecdotally, residents reported varying levels of labor and difficulty while on-call due to patient number, flow and systems-based issues. Residents desired an objective measure to know what was a "hard night" on-call, and a place to document difficulties that arose. An online survey was designed to track the number of patients seen while on-call, and provide a place for residents comment on their nightly experiences. Methods: The on-call tracking tool is an online Google-based survey which measures the number of patients seen by psychiatric residents on-call at GWU; a link to the survey is sent to residents by text message after each call. Residents answer 7 survey questions on the total number and disposition of patients (admission vs discharge)--a proxy for the level of risk each patient presents in their clinical psychiatric assessment. A free text area is available for comments. Data collection began in January 2017 and is ongoing. Results: From January to August 2017, the on-call tracking tool had a 78% response rate for overnight weekday logging. In a call pool of 11 to 13 residents, GWU on-call residents have logged 560 patient encounters, with 246 admissions, 198 discharges from the ED, and 46 submissions for involuntary commitment (FD12). On average, a resident completes 4 patient assessments per night, with 2 admissions and either 1 discharge from the ED, an FD12 submission or a consult from the medical floor. Comment themes cluster around challenges working with ED consultants, often regarding intoxicated or medically complicated patients with psychiatric complaints, as well as systemic issues such as patients in police custody or hospital staffing issues. Conclusion: The on-call tracking tool is a novel way to quantify patients seen on-call in an urban academic hospital setting. Residents are invested in their participation given benefits of quantitative data showing the number of patients seen on-call. These numbers can be used by the department to ensure a proper balance between education and service duties while on-call. Residents also appreciate hearing the themes of comments made by their co-residents about being on-call. Further research includes comparing the volume of patients seen by GWU residents to other programs in similar settings and considering if other outcomes such as PRITE or psychiatry board scores are influenced by number of patients seen during residency.

No. 159

The On-Call Committee: A Venue to Examine and Improve the on-Call Culture Through Learning Objectives, Role Expectations and Forum for Discus

Poster Presenter: Jacqueline Posada, M.D.

Co-Author: Karen Michal Wooten, M.D.

SUMMARY:
While on-call, a psychiatrist elicits and processes sensitive information regarding a patient's mental state and safety; this often happens in a suboptimal environment of sleep deprivation and other demands on time and attention. The demands of call, such as individual performance expectations and systemic issues affecting patient load and sleep deprivation, can contribute to physician burnout. Due to the sensitive nature of our work, the on-call experience for psychiatry must be approached with intentionality and awareness of effects of burnout and sleep deprivation on patient interactions. The ACGME program requirements for psychiatry graduate medical education do not specify learning objectives for call. Learning objectives and mission statements can foster a sense of purpose and mindfulness, which are identified as protective factors against physician and trainee burnout. Several years ago, residents at George Washington University (GWU) had to contend with the educational and service balance of call and identified conflict between supervising residents (PGY 2-3) and supervisees (interns) due to lack of clear learning objectives and expectations for roles while on-call. From this experience sprung the On-Call Committee (OCC) which aimed to provide peer-to-peer support for residents in the call pool and to contribute to an educational, supportive, and encouraging call culture. The OCC identified an opportunity to mitigate resident conflict and burnout by creating a mission statement for the on-call experience, expectations for junior and senior residents, and a venue to foster a sense of inter-relatedness between residents, where they can discuss their experiences and air any grievances with the system or culture of call. OCC representatives created the following mission statements: 1) for the team: to maintain patient safety and provide excellent patient care; 2) for the intern: to develop the skills, knowledge, and discernment of an upper level resident who is capable of taking solo call and eventually full autonomy; and 3) for the upper level resident: to guide, support, teach, and mentor the interns through their development as residents. A set of role specific expectations for upper-level resident and intern was created, disseminated to the residents, and also posted in the call room. Finally, the OCC continues to meet monthly as a place to discuss and fine-tune the mission and learning objectives of call as residents encounter challenging clinical situations. We argue that creation of the OCC allows room for examination of the on-call culture and provides a setting for evaluation and gradual changes to an on-call culture that expects optimal performance in a suboptimal environment. The OCC is a model that can be translated to other aspects of psychiatric practice as it highlights the importance of mission-statement, role expectations and a designated forum for discussion and reflection on objectives and mission of an exacting duty.

Promoting Wellness in Residency: Process Group for Internal Medicine Residents at a Pacific Federal Facility

Poster Presenter: Alexander Kaplan, M.D.
Co-Author: Kinsley Hubel

SUMMARY:
In response to the ACGME mandate regarding promotion of wellness within residency programs, collaboration between the Internal Medicine (IM) and Psychiatry residencies at Tripler Army Medical Center (TAMC) led to development of a process group for the IM residents. The process group developed at this institution consisted of cycles of four groups of residents: the first week consisting of PGY-1 residents; the second week, PGY-2 residents; the third week, PGY-3 residents; and the fourth week, residents from all PGY classes. Each cycle therefore occurred over a four week period. Meetings were protected time in which the residents were expected to focus upon group. Clinical responsibilities were managed by chief residents who were excluded from participating in the groups. The groups were led by a clinical psychologist trained in group facilitation, with a generally unstructured environment. These sessions were designed to allow participants to voice concerns, share experiences, and build connection with the aim of promoting well-being for the individual residents and the IM residency program. The groups were discontinued in December 2017. This may be due to a convergence of factors such as negative feedback about the groups, focus on academic

requirements, and time limitations for IM residents. Therefore, it has been the effort of this team to evaluate the root causes for the failure of this process group. A survey was developed with the following factors in mind: resident perception of the purpose of the group, understanding of meeting attendance and expectations, perception regarding appropriate amount of structure in group, perception whether the group affected professional growth and empathy, and feedback regarding how groups should be structured in the future. It is with hope that this direct resident feedback may lead to formation of a group or relevant activity that is better suited to resident needs and will therefore contribute to improved resident wellbeing. This unique effort continues to serve as a valuable interdisciplinary venture to enhance support for each individual, for one another, and for the greater hospital community.

No. 161

Preventing Burnout: Perspectives of Residents and Faculty in Community-Based Training Programs

Poster Presenter: Ary Kian
Co-Author: Kristen Ironside

SUMMARY:

Introduction: Physician burnout is recognized as a significant problem which affects the health and well-being of individual physicians and also negatively impacts quality of care, patient safety and the overall sustainability of the health system (1). Prevalence studies indicate that one-third to one-half of all residents report burnout (2). A recent systematic review and meta-analysis of interventions to address physician burnout identified several interventions that effectively reduced burnout but concluded that more research is needed about the particular strategies or combinations of strategies with greatest value (3). The authors also recommended research on methods to develop and deploy intervention strategies and suggest that involving local physician stakeholders in the selection and implementation of strategies may result in more effective burnout prevention approaches compared to when interventions are externally developed without local input (3). As a first step in further developing the burnout prevention strategies for the residency programs at Kaiser Permanente Southern California we are conducting formative qualitative research with residents and faculty to learn more about how they perceive the problem of burnout and what they consider effective intervention strategies. Methods: From October to December 2016, we will conduct 14 focus group discussions with residents and core faculty affiliated with seven residency training programs at Kaiser Permanente Southern California including: family medicine (two programs), internal medicine (two programs), pediatrics (one program), psychiatry (one program), and obstetrics/gynecology (one program). The study protocol and topic guides were designed collaboratively by a team including researchers, administrators, residents and faculty. For each of the seven programs, one focus group will be held with core faculty and one with residents of all post-graduate years. All discussions will be audiorecorded and transcribed. Focus group transcripts will be coded using a predetermined list of codes as well as codes that emerge from reading the transcripts. We will present findings on participants' views about burnout including how prevalent it is among residents in their programs, the factors contributing to burnout, its consequences and prevention strategies. We will describe participants' previous experiences with burnout prevention/wellness programs including their views on what worked well and what was less effective and why, and the content and approaches they believe would be effective for future programs targeting residents. Potential Impact: Information obtained from this study will shape the development of burnout prevention programs at our institution, and may inform the design of programs at other graduate medical education institutions by contributing to knowledge about approaches that appeal to the target audience.

No. 162

Sexual Feelings of Psychotherapists: A Cross-Sectional Study

Poster Presenter: Lara Vesentini, M.Sc.

SUMMARY:

Background: Psychotherapists who feel sexually attracted toward clients are a common phenomenon. Studies, mainly from the eighties and nineties, show prevalence rates of sexual attraction

to clients between 60 to 90%. However, these studies are scarce, not having been continued in the last decades, and seldom include how to handle these feelings. Nevertheless, this is necessary because the population of psychotherapists, ethical perspectives, training and education have changed over time. **Aim**: This study determines to what extent 1) psychiatrists experience sexual feelings toward clients in Flanders (Belgium), 2) psychiatrists think that having sexual feelings is discussable in their work-field and 3) psychiatrists state this topic was covered within their education and training. **Method**: Based on earlier scientific studies and interviews with experts, a questionnaire was developed and pilot tested among researchers and psychotherapists in training. To improve response rate the "Tailored Design Method" was followed. In the spring of 2017 a call was launched two times in an online newsletter for psychiatrists with a weblink to the online-survey. In the beginning of 2018 a paper questionnaire and a letter of reminder was sent to the postal addresses of the psychiatrists in Flanders. In the spring of 2018 a second mailing and reminder will be send. Addresses were obtained via the National Institute for Health and Disability Insurance (NIHDI). **Results**: Preliminary results show a response rate of 23% (N=244). About 70% of the psychiatrists state to have been sexually attracted to clients during their career. More male psychiatrists reported this than female psychiatrists (85% vs. 57%). Respectively 40% vs. 12% fantasized about sexual contact with a client, 36% vs 9% felt sexually aroused during a conversation with a client and 30% vs 14% fantasized about how it would be to have a romantic relationship with a client. In addition, 57% of psychiatrists stated that having sexual feelings are barely or non-discussable in the work-field, and 93% reported that there was little or no attention in their basic psychiatric education about how to handle sexual feelings for a client. Compared to systemic (19%), behavior (11%) and person-centered therapists (15%), more often psychoanalysts (46%) reported that this topic was covered within their education and training. **Conclusion**: A great majority of psychiatrists reported to have been sexually attracted to clients during their career, especially male psychiatrists. A fifth of psychiatrists fantasized about a relationship with a client. However, the topic is hardly discussed in education, training or the work field. It is recommended to pay more attention to this topic in education and training, and to consider sexual feelings in the psychotherapeutic relationship as a non-deviant phenomenon.

No. 163

Use of Light Therapy to Improve Resident Wellness and Sleep During Nightfloat

Poster Presenter: Nicholas Edward Mahoney, D.O.
Co-Authors: Sabrina Reed, M.D., Katrina N. Hickle-Koclanes, M.D.

SUMMARY:

Introduction: A nightfloat schedule for medical residents creates an instantaneous unnatural sleep-wake cycle with little time to adapt. Research has varied in terms of the impact of call and nightfloat schedules on resident performance. However, the sleep disturbances caused by these work schedules has shown to be consistently related to worse resident wellness which, in turn, may lead to increased rates of burnout and poorer empathy. Bright light therapy provides a low risk intervention to address the sleep-wake disturbances caused by a nightfloat schedule and has been shown to alter the biological clock by as much as 12 hours in only a few days. We hope to utilize bright light therapy to aid medical residents in adapting to a nightfloat rotation schedule. Methods: We designed a quality improvement pilot study to be implemented within the University of Wisconsin Psychiatry Residency during the first year resident nightfloat rotations of the 2017-2018 academic year (8/14/17 - 6/29/18). Their schedule consists of two 2 week and one 1 week nightfloat blocks (5pm to 5am) spread over the course of the year. Residents were educated to use the lightbox at 10,000 Lux for 30 minutes between 4pm and 6pm starting the Friday prior to their 2 week block and continuing until the Wednesday of the second week. During their shifts over the treatment course, they were also instructed to use the lightbox between 5,000 and 10,000 Lux when sitting at their workstations between seeing patients. Other sleep hygiene recommendations were presented during the initial educational session. Residents were recommended to not use the lightbox during the 1 week nightfloat. Analysis: We will collect data using validated surveys to evaluate resident wellness, sleepiness, and difficulty

sleeping. For each of these categories we will have the resident fill out the survey prior to starting nightfloat, in the middle of nightfloat, and at the end of nightfloat. We will compare for changes in the surveys over the course of the nightfloat rotation. We will also compare the two week nightfloat rotations with the one week control nightfloat rotation. For resident wellness we will use the Brief Resident Wellness Profile. We will measure resident sleepiness with the Epworth Sleepiness Scale. We will assess for difficulty sleeping with the Insomnia Severity Index. We will also gather self-reports on frequency and ease of use of the lightbox and whether or not they used other sleep hygiene techniques. Collected data will then be statistically analyzed using a 2 sample t-test. Results: Data will be collected and analyzed following the final night-float rotation on 6/29/18.

No. 164

Physician Wellness: Comprehensive Evaluation of Stress, Burnout and Depression Effects on Medical Trainee Empathy and Compassion

Poster Presenter: Rustin Dakota Carter, M.D.

SUMMARY:

Introduction: Medical schools and residency programs seek to educate future physicians to be competent, well-rounded providers, capable of evidence-based and humanistic care. These long, arduous years of training strive to produce empathetic, knowledgeable physicians to provide compassionate care in this service-oriented profession (LCME, 2015; ACGME, 2015). Positive clinical outcomes are dependent upon healthcare providers that possess both clinical acumen and understanding of the patient's perspective. However, education across the nation varies in relation to how to develop a healthcare force capable of empathetic care. In addition, a changing healthcare system continues to add demands and stress, and recent research has shown increasing affective disorders in our students and residents. Empathy-related research, especially within healthcare, is sparse. Within the completed research, trends have been identified and theories have been put forth. Few studies have sought to validate those potential influences, especially in relation to increasing educational strains and innumerable knowledge and clinical stressors identified in the status quo of American medical schools and residency training programs (Hojat et al., 2009). Our study seeks to understand the connection between stress, burnout, and depression on empathy in medical residents, including demographic trends and correlation between emotional exhaustion, depersonalization and personal accomplishment (Maslach and Jackson, 1981) with empathy. Methods: This study seeks to address the paucity of literature related to career and educational stress and determine an effect, if any, on empathy in medical students and residents. The Maslach Burnout Inventory (MBI), the Patient Health Questionnaire-9 (PHQ-9) and the Jefferson Scale on Physician Empathy (JSPE) will be utilized to study this relationship. First study to utilize the JPSE and MBI to correlate burnout, stress with empathy. Results: Statistically significant relationship between emotional exhaustion and depersonalization with empathy (inverse correlation); positive correlation between personal accomplishment and empathy. Regression analysis revealed a statistically significant relationship between empathy and stress/burnout, regardless of demographic data; specifically, any trainee that reported high emotional exhaustion and depersonalization reported lower empathy; those that felt accomplished had higher empathy scores. High levels of burnout and depression seen as students and residents progress through medical school and training programs. Statistically significant findings correlated depression with high levels of burnout and low levels of empathy. Conclusions: Indicates strong need for curricular interventions to improve physician wellness and increase physician empathy. Students and residents with low burnout scores and higher feelings od accomplishment proved to have increased empathy and less depression overall.

No. 165

Residency, Motherhood, and Burnout: A Literature Review and Wellness Action Plan

Poster Presenter: Shannon L. Mazur, D.O.
Co-Authors: Kelli Marie Ruby, D.O., Valerie C. Sharpe, M.D.

SUMMARY:

More women are entering residency programs than

ever before. According to the Association of American Medical Colleges, the number of women who enrolled in medical school rose by 6.2% in 2016 and new enrollment in medical school was evenly divided between women and men. As the number of female medical trainees has risen, it has become increasingly important to address issues that specifically impact women during their medical training. Physicians are developing burnout at alarming rates compared to the general population. Most studies looking at gender disparities in burnout have shown that female physicians are at higher risk for burnout than their male counterparts. There is also a large body of evidence showing resident physicians in general are a high-risk population for burnout. Surprisingly, little research has been done to specifically address the risk of burnout in female residents. We hypothesize that, much like their non-resident female physician counterparts, female residents may also be at an increased risk for burnout. This is especially concerning as residency training typically spans part of the prime reproductive years of female residents, potentially placing them at risk during the perinatal period due to the personal demands of pregnancy, delivery, and caring for the newborn. As it is reasonable to expect pregnancies may occur during residency training, tailored strategies for combating burnout in this population must be developed. Preventing burnout, or addressing it early, is a high priority for multiple reasons. Research has shown that physician burnout is correlated with lower quality of patient care. There is also documented risk of depression and anxiety when burnout levels are high. Research shows that when women are depressed or anxious in the perinatal period, it can have deleterious effects on the woman, the pregnancy, and maternal-infant bonding. Therefore, the effect of burnout during the perinatal period could have far reaching implications necessitating distinct prevention strategies for this potentially at risk population during residency training. Utilizing literature review on Pubmed, we summarize what is known about gender disparities in rates of physician burnout and make a case for addressing burnout in female residents, particularly in the perinatal period. We also adapt Mayo Clinic's comprehensive plan for organizational strategies for burnout to address this particularly vulnerable subpopulation. Based on literature review and the Mayo Clinic's framework, recommendations include increasing female leadership, implementing support groups, addressing curriculum adjustments for maternity leave, and fostering a culture of community that supports work-life balance.

No. 166

Treatment Issues in an Elderly Female With Repeat Inpatient Psychiatric Admissions

Poster Presenter: Priyanka S. Adapa, M.D.
Co-Author: Raj V. Addepalli, M.D.

SUMMARY:

Ms. S., is a seventy year old African American widowed female, living alone, with a previous psychiatric history of schizoaffective disorder and a past medical history of uncontrolled diabetes mellitus. She has had over thirty inpatient lifetime psychiatric admissions and a longstanding history of noncompliance. She has been followed by an Assertive Community Treatment (ACT) team for the last two years. In spite of ACT Team follow up, she has had numerous admissions which on many occasions were back to back admissions. Her inpatient stays were characterized by extended periods, some of which were up to sixty days. On one occasion, she was readmitted within twelve hours of discharge. On this occasion, she was admitted for manic and aggressive behavior in the context of medication noncompliance within days of discharge from a different hospital. On our unit, the patient refused medications consistently and was uncooperative with vital signs and fingerstick glucose monitoring. She was observed to demonstrate extreme mood swings, quickly escalating to violent and aggressive behavior towards staff and other patients and then becoming calm. At times, she required intramuscular injections of Haloperidol and Lorazepam to calm her. She refused psychiatric, diabetic, and hypertensive medications, so a forced medication order was obtained through the local mental hygiene court. She showed clinical improvement on a regimen of Aripiprazole titrated to a dose of twenty milligrams per day orally and Sodium Valproate one thousand milligrams per day orally. She was extremely inconsistent on Sodium Valproate so it was discontinued. She was eventually discharged on four hundred milligrams of

intramuscular long acting Aripiprazole. Multiple meetings were held with her ACT team to ensure a safe discharge. Issues which emerged prior to discharge included obtaining her consent to make a duplicate key for her apartment, ensuring that her house was habitable, obtaining a referral for visiting nurse services for monitoring of her diabetes and hypertension, educating her on the importance of diabetic monitoring and compliance with her medication regimen, and obtaining home care services for an adequate amount of time. Unfortunately, she was ineligible for home care services as her personal income was in excess of the threshold required for eligibility. Also, the absence of a responsible family member who could provide adequate support made her discharge challenging. Eventually, she was discharged home with referral to visiting nurse services and ACT Team follow up. This case highlights the challenges in maintaining elderly psychiatric patients with comorbid medical issues who are only partially cooperative with their treatment regimen in the absence of community resources and social supports.

No. 167

Stem Cell Therapy as a Potential Tool in the Treatment of Alzheimer's Disease: A Literature Review

Poster Presenter: Senthil Vel Rajan Rajaram Manoharan, M.D.
Co-Authors: Allen D'Souza, M.D., Veeraraghavan Jairam Iyer, M.D., M.B.B.S., Najeeb U. Hussain, M.D.

SUMMARY:
Background: Globally about 50 million people live with Alzheimer's disease (AD) and it significantly affects the quality of life of the patients. AD is a progressive neurodegenerative disorder characterized by synaptic and neuronal loss. The current pharmacological interventions are not curative and offer only symptomatic relief. Stem Cell therapy has emerged as a potential treatment option in the treatment of AD. Recent years have seen a surge in the number of studies using stem cell therapy to modulate cognitive impairment via various mechanisms. Animal studies have been promising and has given hope for the use of stem cell based therapies. This review aims to examine the current evidence for the use of stem cell therapy as a potential treatment of AD. Discussion and Literature review: Stem cells have the ability for self-renewal and differentiate into different cell lineages. Neural stem cells (NSCs) and Mesenchymal stem cells (MSCs) are commonly used in research. The Neural stem cells in the brain can differentiate into neurons, astrocytes and oligodendrocytes. MSCs derived from bone marrow, umbilical cord blood and adipose tissue can be transdifferentiated into neuronal cells. In transgenic mice models, transplantation of MSCs have shown significant improvement in cognitive function, A-β deposition in the brain and decreased hyperphosphorylated tau. MSCs also modulate neuro-inflammation and an upregulation of anti-inflammatory cytokines has been noted. Cholinergic neurons from nucleus basalis of Meynert (nbM) brain are especially affected in AD. Studies have shown that more choline acetyltransferase was synthesized by modified NSCs and it significantly leads to improved cognitive function. The role of stem cell therapy in clearing up misfolded protein aggregates in mice models of down syndrome has also been noted. Down syndrome patients are at increased risk of AD with progressive memory decline and develop typical plaques and tangles. Results show that soluble growth factors from implanted murine NSCs leads to significant reduction in tau aggregates. Transplantation of murine MSCs from bone marrow into the hippocampus also has been shown to disappearance of A-β deposition after 7 days of transplantation. The use of inducible pluripotent stem cells (iPSC) has also shown promise. MSCs transplantation in a recent open-label phase I trial in humans however did not slow cognitive decline over the 24 months. Conclusion: The Animal models have shown promising results in preventing cognitive decline in AD. However there has been poor translation between animal studies and human trials. Long term studies are needed to evaluate the safety and long terms effects of these interventions. Further studies that mimic AD in humans are needed. A successful translation in human trials would be a giant step forward in the treatment AD leading to improved quality of life.

No. 168

Neuropsychiatric Workup of Well-Formed Visual Hallucinations in Three Older Adults With Varied

Histories of Psychosis
Poster Presenter: Shane Verhoef
Co-Author: Albert Nguyen, D.O.

SUMMARY:
While well-formed visual hallucinations are a well documented component of schizophrenia, they can also be an indicator of neuroophthalmic dysfunction and have many etiologies. For this reason, it is often difficult to determine the level of suspicion to warrant further neuropsychiatric workup in patients with history of psychosis experiencing complex visual hallucinations. We present three cases of patients with strikingly similar well-formed visual hallucinations (VHs) who carry quite different histories of psychosis. One high functioning patient with a lifetime of isolated paranoid delusions developing VHs following head trauma, one patient with schizoaffective disorder presenting extremely agitated and disorganized and another patient with a history of isolated VHs who presents with dementia secondary to cerebral amyloid angiopathy. Each of these patients reported several well-formed visual hallucinations of sexualized content with an unclear path toward neuropsychiatric workup. We will present the findings and explore possible etiologies while highlighting the deficits in knowledge regarding the appropriate diagnostic testing and the lack of known conditions to confidently account for these presentations.

No. 169
Caregiver Burnout: Application of Dialectal Behavioral
Poster Presenter: Theresa Toledo, M.D.

SUMMARY:
Caregiver burnout is a well-documented phenomenon in geriatrics, but there is minimal information on effective interventions. Up to 50% of caregivers have been shown to experience significant psychological distress which can escalate to burnout, depression and anxiety. This is especially problematic in caregivers of patients with cognitive and functional impairments, and these caregivers are at increased risk of psychological distress and poor overall health. There is some evidence showing benefit with Mindfulness-Based Stress Reduction and mixed results from technology-based interventions. Herein, we describe a study where we will screen for burnout using surveys including the Zarit Burden Scale, then compare two voluntary groups of caregivers who present to the geriatric psychiatry outpatient clinic. The experimental group are those that agree to view a 20-minute video that educates patient on caregiver burnout risks and stress reduction strategies based on dialectal behavioral therapy (DBT). The control group will consist of those who opt out of watching the video. Both groups will be given a handout outlining material from the video, and will be monitored by surveys over 1, 3, and 6-month intervals. The goal of this study is to evaluate the impact of implementing a short, easily-administered intervention that caregivers may be able to view in the span of an office visit. DBT was chosen due to its evidence-based efficacy of enhancing mindfulness, distress tolerance and emotion regulation. The concepts used in this intervention are also being used in an intervention for physicians in training as a 90-minute workshop with positive results.

No. 170
Resolution of Severe Psychogenic Dysphagia With ECT in an Elderly Patient
Poster Presenter: Tom Kim, M.D.
Co-Authors: Tariq Allauddin Munshi, M.D., Maria Hussain

SUMMARY:
In this report we describe an 82-year female with a longstanding anxiety disorder who developed severe psychogenic dysphagia, leading to hospitalization due to failure to thrive. Over a course of 3 years, Ms. B initially complained of having to constantly clear the phlegm from her throat, which then progressed to dysphagia and eventually to a fear of swallowing and choking on her saliva. She underwent an extensive workup by a gastroenterologist, otolaryngologist and speech language pathologist that included flexible nasopharyngoscopy, upper GI series, barium swallow and video fluoroscopy. Investigations showed no anatomical or functional pathology to explain her fear/ inability to swallow. Hence, it was concluded that the dysphagia was psychogenic in nature. The geriatric psychiatry team in the community managed her symptoms initially with venlafaxine and then augmented with

risperidone with minimal benefit. She was admitted to the hospital with a BMI of 16.8, and a G-tube was inserted in order to manage her failure to thrive. Although her BMI subsequently increased to 20.1, her anxiety and fear of choking on her saliva continued to persist. The consultation-liaison psychiatry service in the hospital attempted to manage her symptoms with Mirtazapine, Duloxetine and Olanzapine in addition to Lorazepam. Despite this, she had minimal benefit in her symptoms, and additionally developed tardive dyskinesia secondary to the antipsychotics. Due to the side effects and the lack of efficacy of the medications, geriatric psychiatry and the medicine team collaboratively tapered and discontinued all psychotropic medications except Duloxetine, and a trial of ECT was considered to be the best option. In this poster, we describe for the first time the use of ECT to successfully manage a patient with pharmacological treatment resistant psychogenic dysphagia.

No. 171

Pimavanserin for Psychosis in Individuals With Parkinson's Disease: A Systematic Review

Poster Presenter: Silpa Balachandran, M.D.
Lead Author: Piyush Taparia, M.D.
Co-Authors: Rajesh R. Tampi, M.D., M.S., Geetha Manikkara

SUMMARY:

OBJECTIVES: The aim of this systematic review is to identify published randomized control trials that evaluated the use of pimavanserin for psychosis in individuals with Parkinson's disease (PD). METHODS: A literature search was conducted of PubMed, MEDLINE, EMBASE, PsycInfo and Cochrane collaboration databases for randomized controlled trials (RCTs) in any language that evaluated the use of pimavanserin for psychosis in individuals with PD. Bibliographic databases of published articles were also searched for additional studies. RESULTS: A total of two RCTs that evaluated the use of pimavanserin for psychosis in individuals with PD were identified. The first study showed that pimavanserin provided significant improvements in psychosis from baseline as evidenced by a decrease in the SAPS-PD scores when compared with placebo (37% versus 14%, P=0•0006). Patients in the pimavanserin group also had greater improvements CGI-S and CGI-I scores. Additionally, caregivers of individuals in the pimavanserin group reported a reduction in caregiver burden. Participants reported improvements on night time sleep and daytime wakefulness for pimavanserin when compared with placebo. The most common adverse effects were UTIs and falls in the pimavanserin group. A small but clear increase in QTc interval (a mean increase of 7•3 ms) without association to cardiac adverse events was noted in the pimavanserin group. Pimavanserin's treatment effects were not associated with exacerbation of motor disability, sedation or other safety challenges. In the second study, the pimavanserin treated group showed a statistically significant improvements in the global rating of hallucinations (P=0.02, effect size=0.58), persecutory delusions (P=0.009, effect size=0.41), ideas and delusions of reference (P=0.05, effect size=0.36) and global ratings of delusions (P=0.03, effect size=0.53) and thought disorder item of the UPDRS Part I (P=0.05, effect size=0.40) when compared to placebo. However on the principal measures of the efficacy of antipsychotic response to pimavanserin, the SAPS total domain score only showed a trend (P=0.09, effect size = 0.52). The most common adverse events in the pimavanserin group were somnolence, edema and an increase in blood urea nitrogen levels. The study showed that motor functions and activities of daily living were not adversely affected by pimavanserin when compared to placebo. CONCLUSIONS: Available evidence although limited, indicates that pimavanserin is generally well tolerated and is superior to placebo in improving delusions and hallucinations in individuals with PD psychosis at a dose which does not the impair their motor functions. However, more confirmatory studies are required before pimavanserin can be regularly recommended for the treatment of psychosis in PD

No. 172

Suvorexant for Insomnia in Older Adults: A Systematic Review

Poster Presenter: Silpa Balachandran, M.D.
Lead Author: Geetha Manikkara
Co-Authors: Rajesh R. Tampi, M.D., M.S., Piyush Taparia, M.D.

SUMMARY:

Abstract Objectives: The aim of this systematic review is to identify published randomized control trials that evaluated the use of suvorexant for the treatment of insomnia among older adults (?60 years). Methods: A literature search was conducted of PubMed, MEDLINE, EMBASE, PsycINFO and Cochrane collaboration databases for randomized controlled trials (RCTs) in any language that evaluated the use of suvorexant for treatment of insomnia in older adults. Bibliographic databases of published articles were also searched for additional studies. Results: A total of two RCTs that evaluated the use of suvorexant in older adults with insomnia were identified. The first study primarily assessed the safety and tolerability of suvorexant for up to 1 year with the secondary objectives of assessing the efficacy of suvorexant in improving subjective total sleep time (sTST) and subjective time to sleep onset (sTSO) over the first month of treatment. Suvorexant showed greater efficacy than placebo in improving sTST ($p<0.0001$) and sTSO ($p=0.0002$). Suvorexant was generally safe and well tolerated and most patients completed a full year of treatment. The most common adverse effect was somnolence that was reported in 13% of the participants. The second study primarily assessed sleep efficiency on night 1 and at the end of week 4 along with the secondary endpoints of wake after sleep onset and latency to persistent sleep. Suvorexant showed improvements vs placebo on the co-primary endpoints of sleep efficiency at night 1 (10 mg, $p<0.01$) and end of week 4 (10 mg, $p<0.001$). Dose-related effects were also observed for sleep induction (latency to persistent sleep) and maintenance (wake after sleep onset) at night 1 (10 mg, $p<0.001$) and at the end of week 4 (10 mg, $p<0.001$). Suvorexant was generally well tolerated and that the most common side effects were somnolence, headache dizziness and abnormal dreams. Conclusions: Available evidence although limited indicates that suvorexant improves subjective total sleep time, time to sleep onset, sleep efficiency, sleep induction and maintenance in older adults and is generally well tolerated.

No. 173

Hospice Care for a Chronic Mental Illness

Poster Presenter: Gwen A. Levitt, D.O.

SUMMARY:

The primary goal for most medical specialists is to cure the patient, if possible. Most psychiatrists accept the realization that the majority of the seriously mentally ill (SMI) patients do not always have full remission of their symptoms; rarely, if ever, is there a cure. There are a handful of articles in the literature that discuss palliative and end-of-life care in the SMI population. Most tackle the questions relating to competency to refuse care in end-stage anorexia or terminal medical conditions. Professionals in Australia have recommended a staging model related to palliative care provisions for SMI patients. Providers in the United Kingdom and Canada have also written about palliative care in relation to cost-to-benefit ratios and medical economics. Overall, the mental health community seems reticent to discuss and or confront the fact that the very patients they serve may eventually be faced with the need for end-of-life care directly related to their chronic psychiatric illness.

No. 174

Helping Patients Who Are Determined to Die

Poster Presenter: Keelan K. O'Connell, M.D.
Co-Authors: Edmund Grant Howe, M.D., Neda Kovacevic, M.D., Finis Taylor

SUMMARY:

Mr. A is a 30 year-old Caucasian male with a history of schizoaffective disorder refractory to multiple medications, borderline personality disorder, mild intellectual disability, and Hirschsprung Disease requiring stoma placement at age 8. He presented to the ER from a state psychiatric hospital after self-imposed dehiscence of his stoma site in a declared suicide attempt. Mr. A is well-known to the inpatient medical and psychiatric services due to his twenty-year history of frequent hospitalizations for his self-injurious behavior wherein he inserts foreign objects, including drinking straws, forks, and paper money, into his stoma as reported “suicide attempts” or unconscious efforts to cope with distress, communicate his feelings and “cry for help.” His behaviors have resulted in many adverse events, including GI surgeries and a hypoxic brain injury secondary to septic shock. The patient has required so many GI resections that the colorectal surgery team has determined that he has insufficient bowel remaining for any additional surgery should any

future self-injury result in damage severe enough to require surgery. As a result of this determination and of all psychiatric treatment having failed to result in meaningful improvement in the patient's condition or perceived quality of life, Mr. A and his father requested that the patient be given comfort measures only. Mr. A, along with his father, is refusing a surgery to close the wound site. He will die in time without this surgery. It is unclear whether Mr. A's self-injurious behaviors are motivated solely by a desire to end his life or are compulsive. This case raised a number of clinical and ethical issues within the hospital and it offers an opportunity to explore what is optimal treatment in "end-stage psychiatric care." In this poster session, we will discuss the key topics that arose during this patient's long, multi-hospital admissions course and explore core ethical considerations involved in this decision-making process. These will include: - The use of sliding capacity as the standard for life-ending decisions. - Balancing the principles of autonomy and beneficence when considering comfort care for a chronically suicidal, medically compromised patient. - The definition and use of psychiatric hospice care for refractory illness

No. 175

Completion of Advance Care Directives Among Psychiatric Patients in the Outpatient Setting

Poster Presenter: Sadaf Noor, M.D.
Co-Author: Myriane Isidore

SUMMARY:
"Completion of Advance Care Directives among Psychiatric Patients in the Outpatient Setting" Background: Making medical decisions and contemplating how to live the rest of our lives can be paralyzing and mind-boggling. However, it is crucial to discuss such issues because we could end up in critical situations where we are unable to make medical decisions for ourselves. Advance Care Directives (ACD) is a legal document that specifies what actions should be taken in the event that one is unable to make medical decisions due to incapacitation or illness. ACD allows the individual to appoint a health care proxy in order to make sure that his/her wishes are met. To our knowledge, there hasn't been a study done regarding completion of ACD in psychiatric patients however there are several studies that have been conducted in the general population regarding the importance of completing an ACD. The study found that out of a total 7946 respondents, 2093 (26.3%) reported as having completed an ACD and 5853 (74.3%) do not have an ACD. The most common reported reason of not having completed one was "I don't know what an advance care directive is". Objective: The primary aim of this study is to determine how many patients with mental illness such as Schizophrenia, Schizoaffective Disorder, Major Depressive Disorder, Bipolar Disorder, Anxiety Disorder and Substance Use Disorder will complete an ACD's. The secondary aim of the study is to educate psychiatric residents about the importance of having their psychiatric patients appoint a health care proxy to make medical decisions for the patient in case the patient is unable too. Methods: This study is a prospective cohort study, which will be conducted in the Adult Outpatient Psychiatric Clinic of Brookdale Hospital Medical Center (BHMC). The aim is to educate and develop the understanding of ACD/HCP in the patients with mental illness in an academic medical setting. We will ask the patients to complete the Advance Care Directives (ACD) form. We will use the health care proxy form validated by NYS department of health, which includes identification of the patient, appointment of health care agent, alternate health care agent (optional) and health care directives including organ/tissue donation. Patients will be educated about ACD and if they understand, we will ask them to complete the form. Data will be collected regarding how many patients with mental illness is able to complete the ACD form by successfully appointing a health care proxy. An in-service will be provided to the psychiatric residents in the AOPD to educate them about what an ACD is and about the importance of having their patient's appoint a health care proxy. The data will be statistically analyzed to determine how many patients were able to complete ACD. Results: The study commenced on July 2017 and will end on October 2017. Data is still being collected.

No. 176

Examining the Role of Palliative Care in a Patient With Chronic Mental Illness

Poster Presenter: Marissa O. Goldberg, D.O.

SUMMARY:

Ms. B is 62 year-old Caucasian female, with history of unspecified depression, anorexia, irritable bowel syndrome, intestinal-genital tract fistula, and failure to thrive, who presents to the ED with worsening diarrhea. She had recently been seen in the ED multiples times, for complaints of abdominal pain with diarrhea, prior to admission. CT scan without contrast revealed colitis, but further delineation of her colitis could not be made secondary to refusal of multiple diagnostic tests. The patient was admitted to the general medical floor for treatment and psychiatry was consulted by the primary team for change in psychotropic medication. Upon initial evaluation, Ms. B was irritable and provided minimal history, but endorsed multiple symptoms of depression. It was recommended for her to continue her current dosage of Remeron. She continued to refuse medications and medical care during her hospitalization. The patient's condition deteriorated and psychiatry was consulted again, this time to evaluate decision-making capacity regarding treatment. After a thorough evaluation and two second opinions, the patient was determined to lack capacity. Ultimately, the patient's brother assumed control of her treatment. The patient was made DNR/DNI and treated with comfort measures. Upon discharge, she returned to her nursing home with hospice care. This case touches on the sensitive issue of when to consult palliative care in a patient who suffers from chronic mental illness. Little research exists on the role of palliative care in non-cancer patients. This poster will further examine how palliative care can be utilized in patients suffering from chronic mental illness that is hindering medical treatment.

No. 177

Is It Physical Pain, Mental Pain, or Both? How to Assess and Treat Pain in a Patient With Borderline Personality Disorder

Poster Presenter: Marissa O. Goldberg, D.O.

SUMMARY:

SO is a 40-year-old Spanish-speaking only female, with history of borderline personality disorder, who presents via EMS for suicidal ideations, after she was found on a bridge mutilating herself. Patient reported increased depression, anxiety, and auditory hallucinations, as well as recent relapse on alcohol. Patient was admitted to an inpatient dual diagnosis unit, and placed on a 1:1 due to agitation and self-injurious behavior. On initial interview, the patient reported unbearable pain, out of proportion to presentation, and requested narcotics. She admitted to chronic lower back pain and also reported a new diagnosis of uterine cancer. She denied consent to contact the prescriber of her pain medications, or any physician involved with her care and treatment of cancer. Due to unit policy of not being able to confirm a prescriber of medications, or the diagnosis of cancer, she was unable to receive controlled substances. She received intensive group and individual therapy and trials of gabapentin and acetaminophen. She constantly reported extreme discomfort as well as mental distress secondary to her pain. The patient reported no improvement of pain on a daily basis as well as upon discharge. This case presents several issues pertaining to how to adequately assess a patient's pain and help to stratify its origin. This poster also aims to examine how to better assess pain in patients with borderline personality.

No. 178

Case Report Highlighting the Importance of Psychiatric Screening Prior to Spinal Cord Stimulator Implantation

Poster Presenter: Bruce Bassi, M.D., M.S.

SUMMARY:

Patient selection for spinal cord stimulator (SCS) implantation is a complex problem fraught with many challenges. This case report highlights the need for a consensus regarding exclusionary criteria for SCS implantation. Despite the fact that SCSs have been used for roughly 50 years for the treatment of chronic pain, psychiatric screenings have only been mandated for the last two years. Furthermore, there is significant variability of what screening tests are used, and what is done with those test results. A recent, comprehensive review of biopsychosocial risk factors related to poor SCS outcomes suggested a number of exclusion criteria, however many of these psychosocial variables exist among a spectrum, which still leaves much ambiguity when assessing risk. Additionally, most would agree that "active" psychosis or mania would be an absolute

contraindication, but there is little guidance for individuals with well-controlled, previously severe episodes of mania. To further complicate this subject, there have been a number of published articles that claim that outcomes are actually more favorable in individuals “high in joy and mania” as they may be associated with greater optimism and fewer symptoms of depression. This case report of a 45-year-old woman who carried a diagnosis of bipolar I with psychotic features at the time of SCS implantation due to multiple manic episodes which started nine years prior to the implantation. Given the risks involved in removing the SCS, it remained in place for the following 11 years and became the focus of numerous somatic delusions and complaints. It is unclear to what extent the SCS complicated an already complex underlying psychiatric illness, but nonetheless, she has had at least 6 admissions to psychiatric facilities and state hospital in the last two years alone, and two admissions longer than five months each. Even under these most recently established guidelines, her psychiatric history would not have disqualified her, because she was not manic at the time of the evaluation. Chronic pain patients who are considering a SCS have usually previously failed conservative management, and are desperate for relief. Implantation of a SCS is a stressful procedure that, as this case highlights, has the potential to exacerbate pre-existing psychiatric diagnoses. This case supports the idea that all candidates should undergo a comprehensive psychiatric evaluation to help predict and reduce psychiatric complications of SCS implantation as well as enhance practice guidelines for SCS implantation.

No. 179

Postoperative Pain Management of the Opioid-Dependent Patient

Poster Presenter: Christine A. Annibali, M.D.

SUMMARY:

Introduction: Recidivism caused by postoperative drug-induced impairment is prevalent among patients who are opioid dependent. This literature review focuses on alleviating readmission, simply by analyzing one solution – detoxification. Methods: The study is a literature review of all of the detoxification studies that have been performed in the cardiac, orthopedic, transplant, and other surgical subspecialties. Furthermore, within the various fields of surgery, we looked at three demographic groups: non-detoxed opioid-naive patients (control), non-detoxed opioid dependent patients, and opiate-dependent patients who have been detoxed. A PubMed search was conducted looking at several keywords related to postoperative pain management. Results: A total of ten articles were obtained from the literature review with the following breakdown: cardiac (2), orthopedic (2), transplant (2), and miscellaneous (4). Outcome measures, such as amount of opiate use for pain management postoperatively, length of stay, and cost confirmed the benefits of detoxification within these groups. Gaps in the review were primarily in cardiac surgery, where studies were limited in discussing postoperative pain management. Moreover, only two groups were thoroughly compared: non-detoxed opioid-naive patients (control) and non-detoxed opioid dependent patients. The literature did not include opiate-dependent patients who have been detoxed. Conclusions: There is limited research on the topic of pain management, specifically in the opiate-dependent patient population. Due to limited research and gaps within the field, there is a great need for further investigation.

Ketamine-Induced Malignant Catatonia and Treatment With ECT in the ICU Setting

Poster Presenter: Ateaya Ali Lima, M.D.
Co-Authors: Georgios Petrides, M.D., Prathyusha Reddy

SUMMARY:

The patient is a 63 years old Woman with past psychiatric history of Bipolar Disorder type II, no prior psychiatric hospitalizations, no prior history of catatonia or psychosis, and with past medical history significant for vaginal cancer (30 y/a), s/p urostomy, nephrectomy, and ileostomy, multiple bowel obstructions and resulting chronic unremitting pain. She underwent treatment with IV Ketamine for pain and developed catatonia post infusion. Catatonia progressively worsened and the patient was hospitalized in the MICU for hyperkalemia, metabolic acidosis, and autonomic instability. She

was noted to have a score of 21 on the on the Bush-Francis catatonia scale at the time of admission. The patient did not improve after administration of high dose of Ativan and developed aspiration pneumonia and worsening autonomic instability after two days in the ICU. Consultation and Liason team diagnosed patient with malignant catatonia and arranged to administer bedside ECT in the MICU. After one treatment, tachycardia and hypotensive episodes resolved and the patient began to speak. After the second treatment with ECT, catatonic symptoms resolved completely and the patient was transferred out of the ICU. The patient was back to her psychiatric baseline within one week and was discharged home.

No. 181

Loin Pain Hematuria Syndrome: A Clinical Enigma in Psychiatry

Poster Presenter: Neha Pawar

SUMMARY:

Loin Pain Hematuria Syndrome (LPHS) is a rare condition first described in the literature in 1967. No definitive diagnostic tests exists for the syndrome; rather it is a diagnosis of exclusion. Due to limited awareness regarding LPHS amongst clinicians, it is often misdiagnosed as a somatization disorder .Increased awareness about LPHS could lead to earlier diagnosis and immediate treatment preventing the consequence of severe debilitating pain. Clinically, LPHS includes periods of severe uni- or bilateral loin pain, accompanied by (microscopic) hematuria. Multiple theories regarding etiology suggest the possibility of LPHS a variant of vaso-spastic disease, or secondary to irregular deposition of C3 complement component in renal arterioles. In this poster, we attempt to provide an overview of the topic and propose a list of essential investigations so as to prevent the misdiagnosis of somatization disorder. We hope to familiarize our colleagues with the range of salient psychopathological features associated with the syndrome with the help of two case reports.

Psychometric Properties of the Turkish Version of the Illness Management and Recovery Scale

Poster Presenter: Fatma Yasemin Kutlu

Lead Author: Selda Aydin Polat

Co-Author: Bulent Kadri Gultekin

SUMMARY:

Background: The Illness Management and Recovery (IMR) program is aimed at promoting recovery through teaching clients with severe mental illnesses such as schizophrenia. The Illness Management and Recovery Scale" (IMRS) have been developed to monitor the clients' progress towards recovery and better illness management. The previous study has established good reliability and validity for IMRS among patients with severe mental illness. Methods: This study was conducted using a descriptive and correlational design in order to determine the psychometric properties of the Illness Management and Recovery Scale (IMRS) in patients with schizophrenia. The study was conducted between January and March 2017 in Psychiatric and Neurological Disorders Education and Research Hospital, Istanbul, Turkey. The data of this study recruited 75 patients with schizophrenia. In the study, a questionnaire form developed by the researcher and Illness Management and Recovery Scale were used. The Erenkoy Psychiatric and Neurological Disorders Education and Research Hospital Ethical Committee approved the methods of the study. Patients participating in the study and their family members were informed according to the Helsinki Declaration and their written and oral consents were received. Results: The standard forward–backward procedure was applied in the translation of the IMRS from English to Turkish. Item relevance and content validity of the translated version of the IMRS was tested by an expert panel. The CVI was found to be 0.93. The mean participant age was 41.6 ± 10.9 years (18–65 years), 60% (n = 45) were male, 60% (n = 45) were never married. The alpha coefficient for scale was 0.78, and the split-half reliability of the IMRS was 0.71. Conclusion: In the present study, we found that the Turkish version of the Illness Management and Recovery Scale is a suitable instrument for the Turkish population. This study was supported by Istanbul University Scientific Research Project.

No. 183

Resilience and Coping With Mental Disorders During Concurrent Hearing Impairment

Poster Presenter: Mona Abdel-Hamid

SUMMARY:
Resilience and coping with mental disorders during concurrent hearing-impairment Mona Abdel-Hamid, Miriam Basilowski, Kathleen Tretbar, Norbert Scherbaum, Michael Fuchs, Jens Wiltfang, Bernhard Kis Objectives Studies have proven that the hearing-impaired show higher prevalence rates for mental disorders. At the same time, however, this restriction leads to poor access to the health system. Current scientific research has identified various factors contributing to an increased vulnerability for mental disorders during simultaneous hearing-impairment. These factors comprise violent experiences in childhood, onset and extent of the hearing-impairment as well as reduced quality of life. Furthermore, recent therapy research on "resilience" and "protective factors" has identified another important contributor for the development of mental disorders. Besides amount / severity of stress, the "processing styles" of an individual also influences to what extent a mental disease can develop. Methods The data presented in this APA poster were collected among hearing-impaired clients with and without a history of mental illness. Data were collected with the help of paper-pencil tests. Our analysis is based on protective factors, specifically focusing on motivational differences, regulation of emotions and self-efficacy. Results The aim of this study is the conceptual elaboration of a successful management of restrictions with simultaneous hearing loss.

No. 184

Stress Levels in Psychosis: A Comparison Between Stabilized Psychotic Patients and a Control Group From the Community

Poster Presenter: Pablo M. Gabay, M.D.
Co-Authors: Monica D. Fernandez Bruno, M.D., Alberto Montenegro

SUMMARY:
Background: The conceptual model of vulnerability-stress-protective factors proposes that stress plays a key role in schizophrenia and has been the basis for psychiatric rehabilitation of people with severe mental illness (SMI) [1] [2] [3]. Methods: The psychophysiological coherence model of Cardiac Coherence (CC) [4] -in which different emotions are reflected in state-specific patterns in the heart's rhythms- allows having a measure of stress, and shows the autonomic system balance [5] (Figure 1). Higher CC reflects increased parasympathetic coherence and less stress, while lower CC depends on sympathetic activity and shows more stress [5]. In this study, we compared the CC in a group of 22 stabilized patients with SMI living in a halfway house and participating in a Psychiatric Rehabilitation Program with the CC in a group of 31 non-psychotic outpatients and people from the community. The Clinical Global Impression Scale (CGI) and its Severity -CGIs- and Change -CGIc- subscales were taken to assure the psychotic condition. 8 AM Morning blood cortisol was performed to assess biological stress; Trier Social Stress Test (TSST) (Psychological and Physical stresses) [7] [6] was used to measure cardiac coherence (Tables 3 and 4). RESULTS: (Tables 3 and 4, Figure 2). Average morning blood cortisol was higher in controls than in patients (17.98 µg/dl vs. 16.62 µg/dl, respectively), showing lower morning level stress in the latter. Patients showed higher reaction to and better recovery from the physical than the psychological stress challenge. Controls showed higher reaction to psychological stress challenge and the same rate of recovery from physical and psychological stress challenges. Cardiac coherence in patients showed better recovery from physical than from psychological stress challenges. Controls showed no differences. There were significant statistical differences ($p>0.05$) between patients and controls in low and medium cardiac coherence during the psychological stress challenge, and in systolic blood pressure, both in basal line and after the psychological stress challenge. There were also statistical significant differences both in systolic and diastolic pressure between patients and controls after the psychological stress challenge. These differences also repeated after the physical stress challenge, with differences in heart rates. There were also differences in diastolic blood pressure during the physical stress challenge. CONCLUSIONS: We have not found higher sensitivity to stress in psychotic patients versus controls in this sample. Instead, it was the opposite. Even that this sample is too small to give definitely conclusions, it shows that it is possible to build institutions and programs with environments and treatments that allow having

stress factors under control for people suffering from SMI during long periods of time [8].

No. 185

Caring for Caregivers: Understanding and Meeting Their Needs in Coping With First-Episode Psychosis

Poster Presenter: Rachel Dillinger

SUMMARY:

Background: The first episode of psychosis is a trying time for both those diagnosed and those who care for them. While the literature on how to best treat patients is plentiful, literature on how to best support their caregivers is more scarce and less conclusive. Objective: To conduct a literature review to better understand the caregiver experience, determine which interventions most effectively alleviate their burden, and examine which other factors may affect outcomes. Methods: Articles limited to the English language were retrieved from PubMed and OVID using the following search terms: first episode psychosis, schizophrenia, caregiver, intervention, and burden in various combinations. Discussion: Caregivers experience grief, guilt, and anxiety during this time. While concerned for their loved one, their own lives take a back seat and their mental and physical health are adversely affected. Some are better prepared to cope during this time and are typically warm, decisive, confident, and optimistic. Their families are organized and flexible. Others are less prepared to cope, and are more likely to have poor self-esteem, use avoidant coping strategies, and be overly critical. Their families are controlling and have difficulty with communication and balance. These are the people who stand to benefit most from interventions. In terms of effectiveness, the essential aspects of an intervention are psychoeducation, problem solving strategies, peer support, and clinician guidance. A higher level of interaction with facilitators and peers is associated with better results. With effective intervention, decreases in caregiver burden, reported depressive and anxious symptoms, and feelings of shame and isolation are reported. Further, patients experience fewer relapses. While the literature has yet to isolate the key factors in what makes an intervention successful, this review provides suggestions and further illustrates the need for more research in this area.

No. 186

Evaluation of Visual Contrast Processing in Adults With High-Functioning Autism Spectrum Disorder: No Electrophysiological Changes on a Cortical Level

Poster Presenter: Anna Bubl

SUMMARY:

Background: Altered perception of sensory and visual input is a typical characteristic of individuals with high-functioning autism spectrum disorder (ASD). Although an alteration in the visually evoked potentials (VEP) response in the occipital cortex has been documented in children, we saw no change in the visual processing on a very early level, acquired via pattern electroretinogram (PERG), in ASD adults. This study aimed to investigate possible electrophysiological correlates of visual contrast processing of ASD in adulthood at a later, occipital cortical response, level. Methods: 32 high-functioning adult ASD patients (mean age 39±2, 10 medicated with antidepressant), matched with 33 healthy control subjects (mean age 34.4±2.1), were recruited at the Dept. of Psychiatry of the Univ. Hospital of Freiburg (Germany), following a standardized diagnostic procedure congruent to the recommendations of the NICE Guidelines for Adult Autism. We derived the cortical response of the primary visual cortex on phasic reversing checkerboard stimuli (0.51°) of increasing contrast (Michelson contrasts of 1, 3.2, 7.3, 16.2, 36, and 80%) via VEP. The amplitude versus the contrast transfer function across groups was calculated with an ANOVA model (amplitude~contrast x group x medication). Correlations with ASD severity measured by the Autism-Spectrum Quotient (AQ) were calculated. Results: No significant group differences for our main outcome measure were revealed after correcting for age and medication. No correlation between the severity of ASD and our target measures was evident. However, a significant positive correlation of the social skills subitem of the AQ with a medial VEP amplitude was found within the ASD group. Conclusion: To our knowledge, this is the first study in a high-functioning adult ASD sample investigating visual contrast processing via VEP, in response to phasic reversing checkerboard stimuli. Our results are in line with no changes at the retinal level. Although the VEP reflects a later, thus top-

down, modulated response of visual contrast processing, adult ASD patients did not reveal significant changes compared to the control group. Interestingly, ASD individuals with fewer social skills showed higher VEP amplitudes on the electrophysiological performance, possibly indicating a slight impact of the disease severity concerning social issues. Medication had no significant effect on our measures. Since small checkerboard stimuli were presented in our paradigm, our data are not comparable to significant findings in pediatric ASD samples investigating higher spatial frequencies. Further systematic research is needed to understand visual information processing in ASD, especially regarding adulthood.

No. 187

When Genetic Testing Results in More Questions Than Answers in a Patient With Autism and Recent Onset of Psychosis

Poster Presenter: David M. Ash, M.D.
Lead Author: Garima Singh, M.D.
Co-Authors: Geetha Chandrashekar, M.D., Meelie Bordoloi, M.D.

SUMMARY:

Mr. W is a 13 year old Male with a history of Autistic Spectrum Disorder, Oppositional Defiant Disorder, motor and language delays, who presented to the clinic due to recent onset of psychotic symptoms. Psychiatric symptoms on presentation included increasing fits of rage over the past year, paranoia, auditory and visual hallucinations, placing objects in his rectum and bowel incontinence. Physical examination revealed dysmorphic facial features of elongated midface, narrow palpebral fissures mild micrognathia, and distal skeletal features of increased carrying angle, decreased supination, shortened 4th and 5th metacarpals with hyperconvex nails This constellation of findings were suggestive of Fragile X and Velocardiofacial Syndrome. On presentation, Mr. W was evaluated by Pediatric Psychiatry and Neurology as well as a geneticist. Genetic testing by whole genome array as well as whole exome sequencing did not reveal any copy number changes, or deletions that could reconcile the physical, developmental, and psychiatric findings. Prior to the involvement of psychiatry in Mr. W's care, he was managed by physicians in urgent care and occasional follow up by a primary care physician. Management by urgent care and intermittent primary care resulted in multiple medication trials over a short time-span, without success. The combination of multiple failed medications and inconclusive genetic testing, in particular, significantly demoralized Mr. W and his family members. Mr. W was prescribed Quetiapine and titrated up to therapeutic dose. Also, several psychosocial interventions were arranged including intensive education program and a para in the classroom. Mr. W continues to follow up in the clinic. He and his family have experienced relief from their demoralized state because Mr. W has shown significant clinical improvement. Rigid medication management and psychosocial interventions have made a dramatic impact in Mr. W's quality of life. Although genetic testing may be a useful tool to help identify etiology of clinical problems, unexplainable or equivocal results can contribute negatively to a patient's condition.

No. 188

Detecting Motor Deficits in Autism Spectrum Disorder Via Video Analysis

Poster Presenter: Behnoush Behnia

SUMMARY:

Background: Beside the core symptoms, motor deficits such as dyspraxia or abnormal gait are described as one of the characteristics of Autism Spectrum Disorders (ASD). Especially high functioning ASD patients report clumsiness and other symptoms of dyspraxia significantly more often compared to healthy controls. To our knowledge, so far no systematical investigation has been conducted to evaluate these motor deficits using an objective instrument. Objective: In the present study, we aimed to test the hypothesis that ASD patients show specific patterns of motor impairment compared to healthy controls (HCs). Methods: In our experimental study, we examined adult patients with a diagnosis of high-functioning ASD with an IQ > 85 matched for sex, age and IQ. In total, we examined 80 subjects (n ASD = 37, n HCs = 43). Participants performed eleven movement tasks that are well established as tests of cerebellar functioning and have been chosen in regard of morphological and clinical cerebellar impairments in

ASD. Throughout task performance, patients were filmed by the Microsoft Kinect® camera. This method has been evaluated in prior studies with patients suffering from Multiple Sclerosis and Parkinson's disease. Furthermore, we examined participants neurologically to test for possible motor impairments. Results: Preliminary analysis of our data indicate specific patterns of motor deficits in ASD compared to heathy controls. Detailed data will be presented at the APA Annual Meeting during Poster Presentations. Conclusion: Our preliminary results suggest that ASD patients suffer from specific motor impairments. The data reinforces knowledge of clinically described ASD motor abnormalities. Thus, video analysis appears to be a feasible instrument for detection of multiple motor deficits in ASD. This might furthermore hint to a therapeutic potential, e.g. as biofeedback therapy based on video analysis instruments.

No. 189

High-Frequency rTMS in Adults With Autism Spectrum Disorder and Depression: A Pilot Study

Poster Presenter: McLeod Frampton Gwynette, M.D.
Co-Authors: Melanie Gail Wiley, Erin Henneberry, Danielle Waulene Lowe, Hussam Alsarraf, Laura Lohnes, Philipp Summers, Jane Joseph, Gregory L. Sahlem, M.D., Mark Stork George, M.D.

SUMMARY:

Background: Patients living with Autism Spectrum Disorder (ASD) are at increased risk for multiple psychiatric co-morbidities including depression, which worsen function and quality of life (1). Repetitive transcranial magnetic stimulation (rTMS) is a non-invasive brain stimulation technique that is a FDA-approved treatment for Major Depressive Disorder (MDD). However, there is little data for the use of rTMS in ASD for the treatment of depression (2). We hypothesized a standard rTMS protocol for depression would reduce the depressive symptoms for adult patients with ASD and MDD. Secondarily, we investigated whether this treatment would also reduce core symptoms of autism in this population. Methods: Patients 18-65 years old with both ASD and MDD by DSM-V without any medication changes in the last month where eligible for an open label trial with a goal recruitment of 15 subjects. Once consented, 10 Hz rTMS at 100-120% of motor threshold was provided on the left dorsolateral prefrontal cortex (DLPFC) for 3000 pulses per session for 25 sessions. Pre- and post-rTMS assessments of depressive and autism symptoms were collected and preliminary analyses were completed with t-test of pre- and post-TMS behavioral tests. Results: To date, ten patients have been enrolled with seven completing the rTMS treatment, two withdrawing, and one currently undergoing treatment. Preliminary analyses of the seven patients with pre- and post-rTMS behavioral scores suggest a reduction in the Hamiliton Depression Rating Scale compared to baseline (-11.71±7.39, p=0.006). 5 of 7 participants had a "clinical response" defined by 50% reduction, and 3 of 7 participants were in "remission" (Hamilton?7) immediately after rTMS treatment. There was also a significant reduction in the informant-reported Aberrant Behavior Checklist (-29.29±18.81, p=0.006) with 5 of 7 participants having at least a 50% reduction in characteristic autism behaviors. Conclusions: Preliminary data from this novel open label trial of rTMS in Autism Spectrum Disorder and Major Depressive Disorder suggest an improvement in depressive and core autism symptoms after completion of a standard depression rTMS treatment series. Thus, rTMS may be a viable treatment option for both depression and aberrant behaviors in the autism population.

No. 190

Old Controversies and New Developments in Autism Spectrum Disorder

Poster Presenter: Patricia Ann Samaniego Calimlim, M.D.
Co-Authors: Gaurav Kumar, M.D., Emmeline Hazaray, M.D.

SUMMARY:

1 in 68 children are diagnosed with Autism Spectrum Disorder (ASD) Early identification is the most powerful tool to maximize a child's potential and make a difference in their lives. Popular old controversies misinforming the public about causal associations with ASD have consequently led to outbreaks of preventable childhood morbidities and perpetuation of misinformation regarding etiology, diagnosis, and prevention of ASD. Objectives of this poster are (1) to describe popular old controversies from 1998-2017 that have led to public

misinformation and resulting in childhood morbidities. most of which have been debunked by scientific findings against causal association for autism spectrum disorder and (2) to highlight major new developments from the last 5 years in neuroimaging and genomic technology in predicting and aiding early diagnosis of autism spectrum disorder. While children as young as 12 to 18 months may present with behavioral symptoms, with definitive diagnosis by 18 months, implementation of early intensive behavioral interventions can be efficacious in improving cognitive, adaptive and social communication outcomes in young children with ASD. Hence the importance of reviewing and flushing out decades of misinformation and causal misconceptions and highlighting recent scientific technological development to help in making appropriate, earlier diagnoses of autism, with the emphasis on earlier access to resources for individuals with autism.

No. 191

An fMRI Study on Neural Systems for Aesthetic Experience in Patients With Autism Spectrum Disorder

Poster Presenter: Seongkyoung Park

SUMMARY:

Objectives: Some patients with autism spectrum disorder (ASD) reported excellent performance in the arts or music field. In this study, we aimed to investigate whether ASD patients who do not have artistic or savant characteristics show differences from those of general population when they perform aesthetic judgements, and whether there are differences between these ASD patients and the general population in neural activity when performing aesthetic judgments. Methods: We recruited patients with ASD (n=17, ASD group) and healthy controls (n=19, HC group) for an fMRI study. All subjects were scanned while performing aesthetic judgement tasks with magnificent landscape images and fractal images. Differences in brain activation between groups were assessed by contrasting neural activity during the tasks. Results: In the ASD group, aesthetic judgment score of the whole images was significantly lower than that of the HC group. ($p < .029$) During aesthetic judgment task on the landscape images and on the fractal images, ASD group showed less activation in the superior frontal area than HC group, while the angular gyrus, inferior parietal lobule and insula were more activated in ASD group. In addition, during the aesthetic judgment task of the fractal images, ASD group exhibited greater neural activities in the amygdala and middle temporal gyrus (Brodmann area 37) than the HC group. Conclusion: This study suggest that when an aesthetic judgment is performed by ASD patient, the anterior system of the brain including the superior frontal area is less activated, whereas the posterior system of the brain including the parieto-temporal area is overactivated. Thus, the results of this study suggest that brain activity associated with aesthetic experience in ASD patients might be different from that of the general population.

Dissociative Symptoms in a Patient Subsequent to Allegedly Setting Her Husband on Fire: A Case Report

Poster Presenter: Avneet Madan, M.D.
Co-Authors: Michael DiBiase, M.D., Ahmed Sherif Abdel Meguid, M.D., James Lloyd Levenson, M.D.

SUMMARY:

Dissociation is hypothesized to be a protective mechanism in which an altered state of consciousness manifests in reaction to tremendous psychological trauma. Symptoms characteristic of dissociation are an inability to recall autobiographical information, concurrent with confusion or distress. Social, emotional, and daily functioning are often impaired. Alternatively, feigning the symptoms of dissociation can and has been employed as a mechanism in attempting to avoid legal repercussion for criminal actions. We detail the case of a middle-aged female who presented with symptoms which were initially formulated to be the acute onset of a dissociative state following an incident in which she allegedly set her husband on fire. The patient's presentation was striking and consistent, insisting that she was an 18-year-old woman attending college in the 1980s. She was shocked by the notion of having a husband or children and denied knowledge of modern-day technology. The diagnostic formulation became complicated by behaviors during her inpatient stay;

in particular, the patient was not disturbed by her or her mother's physical appearances, even though they had matured well beyond the ages she claimed them to be. This case report focuses not only on the identification and diagnosis of dissociation, but also on the ramifications of this diagnosis related to forensic issues.

No. 193

Dissociative Fugue and Psychotic Symptoms in Undiagnosed Overt Hypothyroidism

Poster Presenter: Jenny Shen, M.D., M.P.H.

SUMMARY:

Ms. W is a 40-year-old Caucasian woman with a history of depression and PTSD admitted to our inpatient psychiatric unit with new-onset auditory hallucinations and persecutory delusions. It was then noted that she may have had at least one instance of dissociative fugue where she wandered around the city, obtained a taser, and tased herself. This information was obtained from police reports, but our patient stated she in fact had no intention of doing any of the reported acts, and cannot recall anything during that entire one-day period. She described the incident as "having a conversation with my daughter one evening… and the next thing I know I'm waking up in the hospital the next day." She states she may have had more than one such episode within the past year, as family members had told her she would do things she could not recall and that she would not characteristically do. Though she had had depression and PTSD for over a decade, she had never had any dissociative or psychotic symptoms until recently. She felt persecuted by a government agency and heard derogatory auditory hallucinations. In addition to an unintentional weight gain of 50 lbs in the past 5 months, she also endorsed fatigue, joint pains, and hair loss. She had no known history of hypothyroidism. On admission, TSH was obtained and came back as 194 uIU/mL (reference 0.27-4.20). Free T4 level was 0.23 ng/dL (reference 0.93-1.70). A thyroid auto-antibody panel was subsequently obtained, which showed elevated thyroglobulin antibody and thyroid peroxidase antibody, consistent with Hashimoto's thyroiditis and overt hypothyroidism. Levothyroxine was promptly started and she began to show normalization of her initially slow psychomotor activity and speech, improvement of low mood, and weight loss. Her working memory started to improve as well, and she did not have any additional auditory hallucinations, delusions, or amnestic episodes. Neuropsychiatric symptoms are well-known to manifest in overt hypothyroidism, including depression, memory deficits, psychosis ("myxedema madness"), even mania. However, there has not been a report of dissociative fugue linked to hypothyroidism. Hypothyroidism is common, especially in females and the elderly. Importantly, untreated hypothyroidism can impair quality of life, increase disabilities, and even progress to myxedema coma and death. Most neuropsychiatric manifestations of overt hypothyroidism are reversible with treatment; however, if the clinician does not maintain a high index of suspicion for an endocrinopathy, then the patient may be subjected to unnecessary psychotropic regimens and consequent side effects, in addition to delaying treatment of their underlying disease. This case serves as a reminder of the variability in neuropsychiatric manifestations of overt hypothyroidism and presents the possible presentation of it as dissociative fugue.

No. 194

A Case of Dissociation Characterized by Retrograde Amnesia, Change in Affect, and Neurocognitive Deficits

Poster Presenter: Josie Pokorny, M.D.

SUMMARY:

We discuss a case seen by the psychiatry consult service of a 48-year-old female who presented with worsening headaches and acute change in mental status eight days prior when she woke up in her home with prominent change in her memory, personality, affect, and functioning. She was unable to recall select autobiographical and episodic memories, for example, she did not recognize her current husband and believed her adult son was still a baby. Her personality and affect took on that of a young girl. She spoke with higher tone of voice, unusual prosody, and limited vocabulary. She exhibited child-like emotions. Family reported that physical and cognitive functioning was also affected with difficulty performing IADLs, complex tasks, or return to work. She endorsed depression and PTSD

symptoms. Relevant social history was a childhood marked by biparental verbal and physical abuse and severe sexual abuse as an adolescent. Physical exam was notable for unsteady gait and cognitive assessment with MOCA demonstrated cognitive impairment with a score of 14/30. Medical work-up included evaluation by the neurology consult service and CT head, MRI brain, EEG, and LP, all negative for pathology, and laboratory tests notable for CRP 15 and WBC 11.9. After the patient was discharged results for serum antibody testing resulted as positive for calcium channel antibodies, N-type, which has been demonstrated to cause limbic encephalitis. The working diagnosis in this case has been narrowed to an episode of psychogenic dissociative amnesia vs. organic amnesia related to limbic encephalitis. The outcome of this case is ongoing. We discuss the diagnostic challenges in identifying cases of encephalitis in a consult psychiatry setting.

No. 195

Acute Temporal Lobe Infarct Presenting With Dissociative Symptoms: A Case Report and Literature Review

Poster Presenter: Rebecca A. Olufade, M.D.
Co-Authors: Jacob Joseph Oyer, M.D., Walter Kilpatrick

SUMMARY:
Background: In the DSM-5, dissociative disorders are characterized by a disruption of the normal integration of consciousness, memory, identity, emotion, perception, body representation, motor control, and behavior. Dissociative symptoms can potentially disrupt psychological functioning. This case explores a patient who was found to have an organic pathology contributing to a constellation of symptoms mimicking a dissociative amnesia. Methods: A 54-year-old male presented to the emergency department after being found wandering his home in a state of acute confusion and disorientation. Psychiatry was consulted to evaluate for global amnesia and possible conversion disorder. On mental status examination, the patient was found to be distressed by his confusion and inability to remember events leading up to his clinical state. His thought process was significant for thought blocking and expressive language difficulty. Collaborative interdisciplinary team efforts were utilized in the work-up of this case. A longitudinal description is provided for the patient's condition and hospital course. Results: As part of the work-up for altered mental status, the medical team had ordered a CT and subsequent CTA of the head which revealed a large 1.3cm lobulated aneurysm at the left MCA bifurcation. Psychiatry consultation service advocated for EEG and MRI, which were obtained. EEG showed the presence of focal slowing seen over the left hemisphere, maximal over the left temporal region. MRI revealed an acute infarct involving the left temporal lobe extending along the periatrial white matter with suggestion of mild petechial hemorrhages. Discussion: The patient had an abrupt onset of confusion that was interpreted as psychiatric in origin. Thorough medical investigation revealed that a temporal lobe infarct was producing dissociative symptoms. Dissociative disorders are a classification within DSM-5 that should be considered when faced with a complex patient case presenting with altered mental status. Conclusion: It is important for Psychiatrists to be aware of dissociative symptoms that can arise from temporal lobe pathology to provide appropriate diagnostic treatment recommendations.

No. 196

"I Saw You Fixing the Cox Cable in My Apartment" Fregoli Delusion: A Disorder of Person Misidentification

Poster Presenter: Amarachi Nwaije, M.D.

SUMMARY:
Mr. B is a 66 year old, single, unemployed AA male with PPH of Schizophrenia and Cocaine use disorder in remission and PMH of HTN, who presented to the ER at the VA hospital for treatment of a laceration he sustained after being hit with an unknown object on forehead. Mr. B reported symptoms of psychosis like delusions of Control stating he believed that people were controlling his bowel movements and urinary frequency leading to multiple bowel movements per day and urinary frequency. He also reported he felt like he was being chocked whenever he ate or drank. He also reported ideas of reference when he is watching TV. Mr. B complained of "seeing people who look like me" and strongly believed they were him. Which cause him tremendous discomfort as he

became isolative and withdrawn on the unit. During meal time he would go to the dining but would not eat any meals. He reported "when I go to sit at my tray, People look at me as if it is not my food, maybe someone else that looks like me". Whenever he was told his Vital signs, he would say "I'm not sure that is mine it appears to be another patients who has my name and appearance." pointing to someone else. He also reported prior to being in the hospital, he was living in an apartment where he was paying his bill consistently until he stopped as he felt like "there was something fishy going on and I started seeing other people's mail/bills coming in my name so I stopped paying the bills" therefore his utilities got cut off. He also reported he stopped paying rent as when he went to pay his rent one of the months, the lady appeared was someone different and didn't pay after wards leading to his eviction. Pt states to one of the nurse on the unit "I saw you on crutches at the store" and the nurse states he has never met the pt. before. He also reported seeing his niece at his local bank where and states "she didn't say anything to me she just walked by". His son claims the niece would not be at the bank as she does not live close to the area. He also told the writer, "I saw you the cox cable in my apartment". He reported symptoms to be intrusive and bothersome. Treatment: Pt was started on Haldol 5mg and Titrated up to 10mg BID and Benztropine 0.5mg BID. Fourteen days into his admission he was given Haldol Dec 150mg IM. His symptoms gradually started resolving and became less intrusive and bothersome. This case also underscores the need for psychiatrists to be aware of this disorder as its initial presentation may appear as pt. is uncooperative/ paranoid and disorganized or malingering to get out of responsibilities. Also, this syndrome ass. with Traumatic Brain Injury.

No. 197

Mental Health Comparative Cost in a U.S. Air Force Basic Military Training Population

Poster Presenter: Christopher Jorgensen, M.D.
Co-Author: Joseph Mansfield, D.O.

SUMMARY:

Background: The United States Air Force recruits thousands of presumably healthy young men and women every year to fulfill vital roles in our nation's military. Despite strict screening measures currently in place, these recruits incur significant healthcare costs while in training . This study investigated healthcare costs associated with basic military training, focusing on costs associated with Mental Health services. Objective: To evaluate direct and indirect costs associated with Mental Health care of Air Force recruits in Basic Military Training. Methods: A de-identified database of psychiatric inpatient information and Freedom of Information Act (FOIA) data regarding U.S. Air Force (USAF) Basic Military Training healthcare costs in Fiscal Year 2015 was used to compile total and average cost per trainee for inpatient psychiatric services. The subjects were adults (18-39). Inclusion criteria was the need for inpatient psychiatric admission during basic military training. Results: In fiscal year 2015, the USAF spent $14,636,400 on healthcare for the 34,242 basic trainees. The vast majority (91%) was spent on care received in Military facilities, but 9% ($1.29M) was purchased in the local market. Of that, Mental Health made up 79% of purchased care expenditures. Conclusion: The costs associated with trainee healthcare are non-negligible. The costs associated with Mental Health care are the second largest healthcare expenditure for trainees and Mental Health makes up the vast majority of purchased care dollars for Basic Military Training. More research is needed to better understand possible ways to decrease the mental health burden on this target population.

No. 198

Is Combat Exposure a Risk Factor for Violence in Veterans?

Poster Presenter: Christopher W. Harris, D.O.

SUMMARY:

At this time, there is little understanding of the risk for violence by veterans of wars of different eras; specifically, if a service member or veteran has been exposed to combat. The various environments and other relevant factors unique to the military, such as war zone experience, PTSD, and other associated psychiatric disorders can lead to different outcomes in risk assessments for violence. One such case to exemplify is of a single 53M active duty infantry officer with two deployments totaling 30 months which included firing weapons as well as other means of violence of combat. Shortly after returning

from his last deployment, he noted difficulty adjusting being back in the United States, to include being sensitive to certain sounds, certain images, and feeling restless and on-edge in certain situations (e.g. large crowds, etc.), but never sought behavioral health treatment. He went on to develop nightmares and began withdrawing, isolating himself inside his home. Years after returning from his last deployment, he described an incident when he woke up in the middle of the night from a nightmare, thinking he was in Iraq. He pulled his firearm and shot off multiple rounds in his home, which resulted in the police being called. Shortly after this incident, he agreed to engage in behavioral health treatment. He was advised to get rid of his weapons, which he agreed to and he said he did. He intermittently engaged in treatment over the next year and a half, endorsing continued worsening symptoms despite various psychotherapeutic and pharmacotherapeutic treatments. One day, when leaving a doctor's appointment and on his way home, he felt threatened by another driver on the highway. Allegedly, he began speeding and driving erratically, and pulled a weapon on this other driver, who subsequently called the police. The police caught up to the patient and he was arrested. A few questions arose as this case evolved: (1) If a veteran has a history of combat-related violence, does that increase his overall risk of violence? (2) What other factors should be included in the unique veteran populations that could yield an increased risk of violence? (3) What screening should there be in veterans with a history of combat-related violence? (4) What interventions would be recommended in someone if they had identified risk factors for violence? (5) What treatment goals or measurable goals would we use to track an individual with increased risk of violence over time?

Digital Ethnography of Veterans With PTSD Who Engage in Health Information-Seeking Behavior on the Internet: Implications for Etherapy

Poster Presenter: Damian Jacob Sendler
Co-Author: Mariusz Duplaga

SUMMARY:

Health information-seeking behavior on the Internet defines searching for answers on one's suspected (or diagnosed) medical condition. This study investigates (1) how U.S. veterans diagnosed with PTSD search for help online, and (2) seeks to define the scope of problems that affect their daily functioning. A selective search of the entire Internet, using the combination of keywords [veteran OR health OR discussion OR forum OR help OR va] was conducted on DEVONAgent Pro in mid-2017. Results yielded over 2932 hits — clusters of websites, published in English, where U.S. veterans engaged in health-oriented discussions. Based on pre-specified inclusion criteria, about 172 sites were selected for qualitative content analysis. Using grounded theory, combined with extraction of demographics — we archived, analyzed, and summarize all significant findings. Thematic analysis identified several themes explaining what kind of health information veterans seek to better understand their functioning with PTSD. These themes include going back to work, vitamin B12 deficiency, diabetes management, Prazosin treatment for nightmares, use of psychiatric service dog, marijuana addiction, sleep apnea, and anger management. In each of these categories, we were able to identify how symptomology of PTSD affects the quality of health information sought online. Furthermore, we collected ethnographic data that explain the "average," digitally-savvy veteran with PTSD who use the Internet to access health information related to psychiatric conditions, and why they are doing so. In the context of V.A. hospital services, we find that the inefficiency of primary and psychiatric care at these hospitals is responsible for prompting veterans to seek help on the Internet — either in addition to, or in lieu of care received at veterans clinics. We define the medical and administrative problems that compromise adequate access to services at V.A. clinics — told from the first-person perspective of participants. Lastly, we define usability of analyzing digital help-seeking behavior in designing and implementing the Internet-based telehealth counseling programs. U.S. veterans with PTSD increasingly use the Internet to engage in health information-seeking discussions. This study shows an innovative way of identifying health concerns of veterans through retrospective text analysis of prior conversations. A subsequent step in health prevention is to reach out to veterans and offer them a targeted survey that might help us uncover more details about challenges surrounding

the quality of psychiatric and general medical care offered at the V.A. facilities. Importantly, this platform of digital ethnography is a pre-requisite step in developing Internet-based interventions, including health platforms - for managing post-deployment veterans diagnosed with PTSD.

No. 200

The Soldier's Heart: A Resource to Improve Understanding of Posttraumatic Stress and Help Improve Veteran's Lives

Poster Presenter: James Mooney

SUMMARY:

Post Traumatic Stress (PTS) in military veterans is a modern health epidemic in the US. It is estimated that up to 20% of Operation Iraqi Freedom (OIF) veterans and 15% of Vietnam Veterans have PTSD in a given year. Furthermore, it is estimated that the actual prevalence of PTS is significantly higher, with up to 30% of Vietnam Veterans suffering from PTS in their lifetime1. Lack of understanding about PTS symptoms, difficulty in finding connections to available community resources, and avoidance of discussing these sensitive topics in healthcare settings all contribute to veterans not accessing the care that they need. Thus, the mission of The Soldier's Heart project will be to provide a comprehensive website that allows veterans, families, providers, and communities to understand the PTS through each other's perspectives, learn of treatments both evidence based and alternative, and better communication between those affected and those who treat them. The Soldier's Heart will utilize short videos, presented by fellow veterans, doctors, caregivers, and families, to communicate personal stories and struggles as well as provide understanding into this exceptionally complex topic. In this way, the Soldier's Heart will work to bridge healthcare gaps between veterans and the resources available for them, with the goal of providing a more comprehensive understanding of PTS while simultaneously connecting patients to resources in their community.

No. 201

Case Report of Graves' Disease and Schizophrenia

Poster Presenter: John A. Lee, M.D.

SUMMARY:

Mr. T, a 32 year old Caucasian male with a past diagnosis of schizophrenia and diabetes mellitus type 1 presents to the Emergency Department after punching his uncle who was driving at the time. Patient had recently been psychiatrically hospitalized 8 months earlier for similar complaints, assaulting his father and mother in the setting of paranoia and psychosis. Patient's father reported that the patient had been adherent to medications and outpatient follow up but continued to exhibit worsening psychotic symptoms. In the hospital, the patient remained violent and psychotic despite trials of various anti-psychotics, anxiolytics and mood stabilizers. The plan was to trial lithium to treat his aggressive behaviors and thyroid studies were obtained prior to initiation. He had a very low TSH and a high free T4. His thyroid stimulating immunoglobulin level was elevated and he was diagnosed with Graves' disease. He was initiated on methimazole for his thyroid condition and his violent behavior ceased and his psychotic symptoms lessened. The last thyroid studies were obtained from 5 years prior, as a part of the initial work up for first break psychosis which did not show any abnormalities. Currently there are no ADA/APA guidelines regarding thyroid studies. This case illustrates that patients with schizophrenia may continue to require thyroid studies as part of their psychiatric care. Furthermore, the index of suspicion should be elevated in schizophrenic patients with diabetes mellitus type 1 as there is an auto-immune mechanism related to both diabetes and thyroid disease. Considering that schizophrenic patients will have exacerbations of their illness with symptoms that overlap with symptoms of hyperthyroidism, it may be prudent to perform an annual TSH or if they have an exacerbation of their psychosis.

Extended Psychosis Following Methamphetamine Use: A Case Series and Review of the Literature

Poster Presenter: Ruthie Cooper

SUMMARY:

Methamphetamine is produced using chemicals including pseudoephedrine, battery acid, and

antifreeze, and can produce psychiatric symptoms such as increased energy, irritability, and decreased appetite and sleep. Residual damage to dentition, memory, and solid organs such as the heart and kidneys can occur, although the mechanisms of such damage remain poorly understood. A dose-response relationship between methamphetamine use and psychotic symptoms has been established but little information has been published on the total duration of such symptoms. Lifetime prevalence of meth use in the United States is estimated at 6.4%, with nearly half a million individuals estimated to use per month. We present a case series of prolonged psychosis with paranoid features induced by methamphetamine ingestion, in individuals with no personal or family history of psychotic disorder. These cases serve to address the topic of prognosis and duration of psychosis associated with meth use.

No. 2

White Matter and Bile Duct Changes in a Patient on Chronic Methadone Maintenance Therapy

Poster Presenter: Sebastian Cisneros, M.D.
Co-Author: Douglas Opler, M.D.

SUMMARY:

Introduction: Emerging evidence suggests that long term methadone use may lead to adverse effects. White matter damage has been seen in the superior and posterior corona radiata, and the posterior limb and retrolenticular internal capsule (1). Radiological studies show increased bile duct diameter in patients on chronic methadone maintenance compared to controls (2). A high rate of constipation is seen in these patients (3). We present a case which highlights potential medical adverse effects of chronic methadone therapy. Case Report: Mrs. A is a 40-year-old female with opioid use disorder on maintenance treatment with methadone 175mg/day, cocaine use disorder in full remission, depression, and gastric bypass. She presents to the hospital with lethargy, intermittent diffuse abdominal pain in the right upper quadrant, fatigue, poor oral intake, bilateral foot pain and paresthesias, chronic constipation and unintended weight loss. Before admission, she was diagnosed with systemic lupus erythematosus, multiple sclerosis and hemochromatosis. She was admitted to medicine. Autoimmune profile, hepatitis panel, cryoglobulins, HIV screen, RPR, zinc, copper, iron, vitamins, blood and urine cultures and EMG were unremarkable. Ultrasound showed common bile duct dilation of 9mm, confirmed on MRCP. HIDA scan was negative for cholelithiasis. Liver biopsy showed moderate to severe fatty change. MRI showed two 2 to 3mm subcortical white matter T2 hyperintensities on the left anterolateral corona radiata and superomedial frontal lobe. Discussion: Opioid use disorder is a dangerous illness, the course of which can be mitigated by opioid maintenance therapy, including methadone, which has helped many patients to successfully manage the illness. Long-term methadone use has its own risks, however. A knowledge of these can assist clinicians in choosing between alternative treatments of opioid use disorder, such as naltrexone or buprenorphine. Conclusions: Options for long-term management of opioid use disorder should take into account the potential long-term adverse effects of methadone maintenance, including white matter changes, bile duct dilation, and chronic constipation. When methadone is chosen as the therapy of choice, the clinician should be alert to these potential adverse effects so as to properly recognize and address them.

No. 3

Recent Discoveries in the Neuroinflammatory Process of Alcohol Abuse

Poster Presenter: Shram Dinesh Shukla, M.D.
Co-Authors: Lan-Anh T. Tran, D.O., Vanessa E. Freeman, M.D., Corinde Wiers

SUMMARY:

The neuropathology of alcohol addiction involves well-known brain structures and neuroinflammation may explain the neurotoxic effects of alcohol abuse. We aim to review the last few years' worth of research in neuroinflammation and alcohol abuse in an effort to summarize the recent findings. Neuroinflammation is a process by which microglia, the resident immune cells, are activated in response to CNS injury.1 Imaging studies have provided insight into microglia's activity by studying its activation through the translocator protein, TSPO, in PET imaging scans. Such neuroimaging has revealed a relationship between microglial activation and neuropathology in depression, psychosis, cocaine

abuse and even methamphetamine abuse.2-5 When examining recent literature on neuroinflammation in alcohol abuse, animal models have provided a baseline understanding that alcohol induces NRLP3-inflammasome pathways and Mitochondria-Reactive Oxygen Species (ROS) in cultured microglia cells.6 Interestingly, other recent studies reveal that: 1) ethanol may mediate neuroimmune expression through dosing (rather than loading), 2) binging patterns of alcohol abuse upregulated neuroinflammatory pathways but certain genetic knockouts protected these animals from alcohol-induced neurotoxicity, 3) alcohol deprived mice displayed anxio-genic behaviors but also certain genetic knockouts protected these animals from displaying such behavior, and 4) chronic alcohol abuse was associated with higher levels of neuroinflammatory markers in locations such as the hippocampus and cerebellum.7-11 Few recent studies have looked at human subjects, but one study analyzed induced pluripotent stem cells, iPS, and neural progenitor cells, NPCs, finding that ethanol exposure resulted in NRLP3-inflammasome pathways and a subsequent decrease in the number of mature neurons.12 If clear biological markers elucidate, even if only in part, the underlying mechanism of alcohol addiction and its downstream effects, then they also provide an intriguing point in the process for potential intervention. With the rise of immunomodulators, targeted pharmacotherapy may be a part of the answer for treating alcohol abuse and addiction moving forward. Nevertheless, recent advances continue to build upon our understanding of alcohol addiction and further contribute to the study of neuroinflammation.

No. 4

Synthetic Cannabinoids: Fake Pot; a Potential Threat

Poster Presenter: Sumayya Binth Ayaz, M.D.

SUMMARY:

The use of synthetic cannabinoids (SC), commonly known as “K2”, or “Spice” is alarmingly high, especially among young people. 11% of high school students in U.S reported using K2, making it as the second most frequently used illegal drug among high school seniors after marijuana. (1) Originally produced to treat medical conditions SCs were later used by clandestine laboratories that modified the chemical products and marketed it as herbal mixtures. K2 became widespread because it is easier to obtain, cheap, highly potent, and is not detected on regular toxicology screen (2). Many teenagers are drawn to it because of the misperception that spice products are natural and therefore harmless. But the real picture is far from that perception. Synthetic cannabinoids detected in this herbal mixture has shown to be more potent than tetrahydrocannabinol, the primary psychoactive compound in Marijuana, resulting in serious medical and psychiatric adverse effects including vomiting, hypertension, and tachycardia, shortness of breath, seizures, anxiety, agitation, paranoid behavior, hallucination and suicidal ideation. The U.S Drug Enforcement Administration classified most prevalent SC as controlled substances but this regulatory effort is complicated by 1) Continuous change of chemical component by the clandestine laboratories and 2) Lack of a standardized test to detect the synthetic cannabinoids. This review poster highlights the emergence of SC abuse; describes the adverse effect of these products, the barrier to legal regulation and the need to develop a standard screening test to identify the products

No. 5

Meeting the Challenges of Heroin Addiction in the Tribal Areas and Peshawar, Pakistan: A Nongovernmental Organization’s Observations and Experiences

Poster Presenter: Tariq Mehmood
Co-Author: Rohul Amin, M.D.

SUMMARY:

The Golden Crescent, a region encompassing Afghanistan, Pakistan and Iran continue to be devastated by the heroin endemic. The geopolitical influence of wars and political instability has led to Afghanistan becoming the lead producer of illicit opium in the world. Pakistan’s Federally Administered Tribal Areas (FATA) and the capitol of Khyber Pakhtunkhwa (KPK) province, Peshawar lie on the cross-roads from Afghanistan where the historical silk road once existed. Due to the easy and cheap availability of heroin and other drugs, the addiction to these is now endemic. This is among a region that already suffers from severe poverty,

political instability and resource-constraints. The region naturally relies on Non-Governmental Organizations (NGOs) such as ours to tackle this challenge. We attempt to provide a shared mental model of this problem by sharing our experiences treating heroine and other illicit substance addictions in this region as the largest NGO. We rely on unique protective factors associated with Pashtoon tribal and collective extended familial factors, Islamic religious and spiritual interventions, and modern detoxification methods using limited resources. Our NGO, The Dost Welfare Foundation, consist of #### inpatient long term rehabilitation facility. Due to the shift in traditional heroine smoking to intravenous use, additional challenges are addressed to including chronic hepatitis and HIV/AIDS. Besides describing our methods and techniques, we also provide demographics and outcomes of about 5000 patients who have undergone addiction treatment at our facility.

Vivitrol as an Effective Management Option for Post-Bariatric Surgery Addiction Transfer: A Case Series and Literature Review
Poster Presenter: Tymaz Adel, M.D.
Co-Authors: Ammar Y. Ahmad, M.D., Mehwish Hina, Zohaib Majid, Asghar Hossain, M.D.

SUMMARY:
The obesity epidemic is on the rise with major short-term and long-term implications and global health impact. U.S. survey data demonstrate that 68% of Americans are overweight and 33.8% are obese, with bariatric surgeries in 2015 totaling 196,000. Concurrently, substance addiction, particularly alcoholism, poses significant burden to an already overwhelmed state of national debt via increased health-care costs and an overall negative impact on global health. Data demonstrate that alcohol-related disorders cost the United States almost $225 billion a year and, according to the Global Burden of Disease study, alcohol use is the fifth leading cause of disease worldwide. Bariatric or weight loss surgery (WLS) has been known to alter alcohol metabolism resulting in a higher prevalence of alcohol use problems post-operatively, thereby addressing one major epidemiological problem but potentially precipitating an even more burdensome one. A retrospective study by Ertlet et al concluded that a small percentage of patients (less than 3% of their sample) spontaneously developed alcohol dependence approximately 7 years after surgery. Another retrospective study found that 28.4% of participants reported having a problem with alcohol after WLS compared with 4.5% prior to WLS. Central to obesity and addiction is the concept of "addiction transfer," which helps us understand the rationale behind these data. Insulin, dopamine, opioid receptors, the mesolimbic reward pathways and the hypothalamus interplay in the regulation of feeding and addiction behaviors. FDA-approved treatments, i.e. Contrave (naltrexone HCl and bupropion HCl) or Vivitrol (naltrexone), already exist for chronic weight management and alcohol dependence, respectively, spurring the emergence of treatment options that are gaining increasing validity via the inter-relatedness of these two epidemics. In this case series, we will report two outpatient individuals, who developed alcoholism post-gastric bypass surgery and have successfully maintained remission of both food and substance addictions with once monthly Vivitrol injections. We aim to illustrate the importance of this connection between food and substance addiction, particularly with regard to the concept of "addiction transfer," in order to effectively treat this current, and very relevant, subset of individuals. We will also conduct a literature review of data over the last 10 years regarding the efficacy of treatment options for addiction in post-gastrectomy patients and highlight the neurohormonal mechanisms involved in food and substance addiction.

No. 8
Does Parenthood Influence the Rates of Quitting Smoking?
Poster Presenter: Verena Santos
Co-Author: Andre Malbergier

SUMMARY:
Background. Some studies have assessed the influence of pregnancy in women's smoking. In these cases, tobacco cessation is very common (Tong, 2013), even without aid or treatment (Solomon,

2004). However, maintaining abstinence after this period seems to be difficult (Coleman-Cower, 2014). The aim of this study was to evaluate if having children (from 3 to 10 years old) influences smoking cessation rates. Methods. This research was carried out in a specialized and academic service for drug dependence treatment in Brazil. One hundred and twenty four patients were assigned to receive varenicline titrated to 1 mg twice per day and 6 sessions of group psychotherapy. Sixty two (62) patients had children from 3 to 10 years old and 62 patients did not have children. Smoking status, cigarette craving, use of medication, side effects, and psychiatric symptoms were assessed during treatment. Carbon Monoxide was measured in every evaluation to compare with smoking self-report. The ?2 test and Fisher's exact test were used to compare categorical data and parenting. The Mann–Whitney test was used to analyze the association between parenting status, number of quit attempts, smoking initiation and number of cigarettes smoked per day. Survival analysis, using the Kaplan–Meier method and the Wilcoxon test, was used to examine the association between parenting, relapse and treatment dropout. Results. The number of parents who quit smoking by the end of treatment (12 weeks) was similar to non-parents, 35 (56.5%) and 36 (58%), respectively (p=0.85). After 6 months and 12 months of treatment the numbers of patients who remained abstinent were also similar between the groups. At 6 months 30 (48.4%) non-parents and 23 (37.1%) parents were smoke-free (p=0.241). At 12 months, the rates were 22 (35.5%) for non-parents and 19 (30.6%) for parents (p=0.568). The number of participants who quit treatment and the decrease in the number of cigarettes smoked per day were also similar between groups. Conclusion. Although pregnant women and mother of toddlers tend to present higher rates of quitting smoking, our study did not find any differences in treatment outcomes between parents of children from 3 to 10 years and non-parents. This data should stimulate health care policy makers to develop motivational strategies to reach this group of parents as second hand smoke is an important issue for young children (from 3 to 10 years old). This study was supported by Pfizer, Inc.

Case Series With a Feasibility Study of an Online Opiate Dependence Service

Poster Presenter: Wiktor Lucjan Kulik, M.B.B.S.
Co-Author: Cyrus A. Abbasian, M.D.

SUMMARY:

Co-authors: Wiktor Kulik, M.D., Cyrus Abbasian, M.D. ndence service Abstract: Background: The profile of patients addicted to opioids in the Western world is changing, with increasing number of people becoming dependent on prescription analgesics. Many face significant barriers to treatment. In the UK, the National Health Service (NHS) drug and alcohol services are tailored towards the complex, severe and chronic end of the addiction spectrum. Significant stigma prevents attendance at drugs treatment facilities for those who do not fit this profile. We have developed a confidential internet based psychiatric service to provide greater access for this patient group. Method: At UK's only online psychiatry practice we provide a range of psychiatric services and to date have assessed and treated over 750 self referred patients. We have an Adult ADHD service which involves prescribing controlled drugs after an online diagnosis. We are now looking to develop an online supervised opiate substitution service with buprenorphine orodispersible film, based on a similar model. We will present case series of patients seen in our service, compared to UK benchmarks, and the model we have developed to safely diagnose, treat and supervise patients with opioid addiction online. Results: So far 10 patients with addictions have been assessed by Psychiatry UK; 9 males, the average age being 30, 7 White British, 2 having had a previous history of opioid dependence, 5 dual diagnosis, 2 behavioural addictions, with 2 completing treatment. We will present feasibility study of using buprenorphine orodispersible film for supervised maintenance treatment online. We shall compare these with national data for outcomes used as a benchmark. Also will cover limitations to online treatments and how these can be overcome. Conclusions: An evaluation of opiate addiction treatment online; in terms of safety, effectiveness, responsiveness and accessibility. This study is supported by Martindale Pharma and Psychiatry-UK LLP.

Bidirectional Relationships of Psychopathology

With Internet Addiction in College Students: A Prospective Study
Poster Presenter: Yen-Ju Lin
Co-Author: Cheng-Fang Yen

SUMMARY:
Background: The aims of this study were to evaluate the prediction of psychopathology on the occurrence and remission of Internet addiction, and to determine whether Internet addiction will influence the change of psychopathology among college students during the follow-up period of one year. Method: A total of 324 college students participated in this study. Their levels of Internet addiction and psychopathology were assessed by using the Chen Internet Addiction Scale and the Symptom Checklist-90-Revised (SCL-90-R), respectively at baseline and one year later. Results: The results indicated that more severe psychopathology on somatization, obsession-compulsion, interpersonal sensitivity, depression, paranoid, and additional appetite and sleep problems on the SCL-90-R might predict the incidence of Internet addiction during the follow-up period of one year. Moreover, psychoticism on the SCL-90-R in the Internet-addiction group increased more significantly than those in the non-addiction group. Conclusions: The results of the present study supported that psychopathology may predict the incidence of Internet addiction, whereas Internet addiction at baseline may increase the severity of psychoticism.

Alcohol and Opiate Addicted Patients: Clinical Differences on a Chemical Rehabilitation Unit
Poster Presenter: Michael Ramses Habib, M.D.

SUMMARY:
The current study investigates the construct validity of the Inpatient Treatment Alliance Scale (I-TAS; Blais, 2004). The I-TAS is a brief patient-reported measure of treatment alliance between the patient and their entire treatment team. The current study included 105 rehab inpatients who completed the I-TAS at discharge and compared this to scores a therapist rated object relations scale and a psychiatrist rated readiness for inpatient psychotherapy scale. Results showed that the I-TAS was related to the other two measures in theoretically meaningful ways.

Drunken Madness: A Unique Case Report About Alcoholic Hallucinosis
Poster Presenter: Musa Yilanli, M.D.

SUMMARY:
Alcoholic hallucinosis (AH) is a well-known disorder as a complication of chronic alcohol abuse. Vivid auditory hallucination usually experiences just after alcohol cessation. Those hallucinations may occur after a long time of heavy alcohol consumption. The course and presentation of the disease show differences. It may progress over the time by persistent delusions with clear sensorium that resembles schizophrenia. We have a 65-year-old male with a history of alcohol use disorder and a remote history of polysubstance abuse (cocaine, heroin, amphetamines, mushrooms, and many others) presented with mild memory problems, delusions, and vivid hallucinations. Patient states that he sees, speaks with and interacts with his mother who deceased 20 years ago. These symptoms began only 2-3 months ago after being discharged from alcohol rehabilitation center. His UDS was negative. Patient reports no previous psychiatric diagnoses. The patient had been drinking average 25-40 standard drinks more than 40 years

but he has abruptly stopped 2 months ago. The patient was alert and oriented to person, place and time. He was feeling anxious whenever he became hallucinated. He believes that his mother is alive and he has a phone conversation where he is holding his own cell by calling random numbers. He admits he has an active conversation with his mother while he is eating his dinner. Patient smells and feels her. He remembers that he went to his mother`s funeral 20 years ago but he says "I am seeing her as a real person. Not like a spirit". He confabulates to fill in gaps of memory about recent events. The patient was diagnosed as alcoholic hallucinosis and Korsakoss psychosis considered as rule out the diagnosis. Risperdal was started and responded well to treatment. In this poster, we will present a unique case about alcoholic hallucinosis with a treatment. We will discuss the diagnosis with differentials and treatment options of alcoholic hallucinosis.

Mania and Rhabdomyolysis: Weight Loss Pills Come With a Cost

Poster Presenter: Musa Yilanli, M.D.
Co-Author: Anita Kumar Chang, D.O.

SUMMARY:

Obesity is a common problem for the American population, especially the patients who diagnosed with bipolar disorder [1]. And so the market for diet pills, like Hydroxycut, has only grown in recent years. Rhabdomyolysis related to Hydroxycut has been described in a few cases [2,3] and mania associated with the same has been described in one case [4]. The case presented here describes a unique situation of both rhabdomyolysis and mania probably associated with the use of the advertised therapeutic dose of Hydroxycut. A 21-year-old young man presented to the hospital with irritability, grandiosity, increased goal-directed activity, decreased need for sleep, which appeared different from his typical psychotic episodes. He was found to be in fact manic and suffering from mild rhabdomyolysis. Aside from having stopped his antipsychotic for the last month, the patient admitted to use of Hydroxycut 2-3 tablets daily. He was admitted to the medical floor and started on IV isotonic fluid. His antipsychotic was restarted after the evaluation in the ED and the Hydroxycut was stopped, bringing him back to baseline within 4-5 days. The case presented here provides an example of two major potential adverse effects (mania and rhabdomyolysis) of the Hydroxycut pills. Even though our patient had multiple risk factors for rhabdomyolysis including history of using aripiprazole, carbamazepine and seizure disorder, the patient had been using these medications without any side effects in the past and his family had never witnessed any seizure-like activity for a long time. He had never presented to hospital with a manic episode. He had stopped aripiprazole treatment 1 month prior to presentation. We may conclude that rhabdomyolysis associated with adding hydroxycut on top of carbamazepine. While many Americans look for quick fixes to the obesity epidemic, caution should be provided by the medical community as these weight loss supplements are not without potential harm.

No. 15

Priapism Associated With Multiple Psychotropic in a Child: A Case Report

Poster Presenter: Musa Yilanli, M.D.
Co-Author: Umair A. Daimee, M.D.

SUMMARY:

Priapism is a urological emergency which is potentially painful and prolonged erection in the absence of any stimulation. Drugs especially antipsychotics count one of the most common reasons in the psychiatry clinic. [1] In the literature, underlying mechanism of priapism associated with alpha-1 adrenergic receptors which located corpora cavernosa of the penis [2]. We present 14 yo caucasian male with the history of Disruptive mood dysregulation who presented to the hospital with prolonged erections which is secondary to clozapine. As per medical records, priapism episodes occurred even with Clozapine, Olanzapine alone and Trazadone with Haldol treatment. During the last hospitalization, Clozapine was tapered off and he was started on Iloperidone. Due to the partial response, clozapine gradually titrated to a lower dose than the initial dose. He was stable on this regimen without any episodes of priapism and discharged. After discharge, Clozapine was discontinued due to multiple episodes of priapism. Patient had experienced at least 2 episodes of

priapism which lasted more than 4-8 hours. The patient was taken to an emergency department where he was assessed by a urologist. After multiple procedures to alleviate pressure priapism subsided and he was discharged back to State hospital. Clozapine had restarted because of poor response to other medications. Discussion: Drug-induced priapism is not associated with either the dose or the duration of treatment. [3] The underlying mechanism is related to alpha1 affinities of antipsychotics. The newer atypicals including clozapine, quetiapine and olanzapine have higher affinity. [3] Eventually almost all antipsychotic medications have been reported to cause priapism rarely. [4] This case is so unique due to priapism which is secondary to Clozapine, Trazadone and Olanzapine treatment. The patient who is at risk for priapism, selection of psychotropics medication, especially with low a-adrenergic antagonism, may preferable

Alcoholic Hallucinosis

Poster Presenter: Romil Sareen, M.D.

SUMMARY:

OBJECTIVE: Take a look at an unusual presentation of alcoholic hallucinosis and the problems faced by the treatment team in diagnosing, obtaining collateral and management BACKGROUND: Alcoholic hallucinosis is a complication of chronic alcohol withdrawal. It is most commonly characterized as visual hallucinations (although auditory and tactile hallucinations are possible), clear sensorium, and normal vital signs along with paranoia and fear. Manifestations may occur as early as 12-24 hours after the last drink and usually resolve within 24-48 hours. It is vital to distinguish Alcohol hallucinosis from DTs as the two phenomenon are often confused but the symptoms and clinical presentation may be a lot different. Our patient is a 29 year old Hispanic male who was brought in by ambulance after he sliced off his 2nd and 3rd fingers of the left hand, reported eating one of the fingers and tossing the other one somewhere in his house and then gnawing at his left forearm. The case will examine difficulties coming up with an accurate diagnosis as our patient was an unreliable historian and it was unclear if this was a suicidal attempt, new onset psychosis or secondary to acute alcohol intoxication vs withdrawal.

No. 17

Managing Mental Illness in an Intellectually Disabled Patient

Poster Presenter: Romil Sareen, M.D.

SUMMARY:

The repercussions of closing down residential facilities for Individuals with Intellectual Disability Abstract Intellectual disability (ID) is a term used to define a developmental disorder characterized by both intellectual and adaptive functional deficits(1).The term has replaced “mental retardation” in DSM-5 which presents a welcoming change from the negative perception of mental retardation in the general population and the medical community(2). Individuals with intellectual disability face challenges in major aspects of life including social, financial, academic and most importantly residential. These challenges become graver when these individuals have co-morbid mental illness because it becomes difficult to differentiate psychological from behavioral symptoms. It is imperative for clinicians be extremely careful before formulating a diagnosis for them and also to formulate interventions that cater to them behaviorally and intellectually. One of the most important aspects of care for these individuals is proper housing placement. In a landmark Supreme court decision in 1999 (Olmstead v. L.C.), it was ruled that states needed to eliminate unnecessary segregation of people with disabilities and ensure they receive services in the most integrated setting appropriate to their needs(4). Intellectually disabled individuals with mental illness must be properly evaluated by clinicians to assess the level of supervision required to ensure proper mental health care. The law allowed these individuals to be able to meet their greatest potential by ensuring proper psychiatric care and opportunities to socialize with patients that have psychiatric conditions with similar severity. The closing down of Willowbrook State Developmental Center in 1987 in New York after the discovery of the inhumane inpatient conditions of patients with intellectual disability sheds further light on the plight of such patients(5). Due to the lack of such facilities and resources, the institution at

the time was housing 6,200 patients despite its maximum capacity of 4,000 (5). In 2013,the Commission on Quality of Care and Advocacy for Persons with Disabilities conducted a review of the Bernard Fineson Developmental Center(6). The findings suggested that there had been ongoing abuse of residents since the year 2010 and active treatment goals and objectives were not revised or implemented(6).A suitable housing option for these individuals would be a medical home model with a coordinated residential setting focusing on the quality and safety of patients. Although the state department has made various efforts for proper placements of these individuals, there still remains a large patient population without proper disposition. Frequently, such patients end up at various CPEPs across the state and are stuck there until a long term housing option can be worked out preventing them from thriving and function as equal members of society. Our case looks at one such patient who was admitted to our service and had a diagnosis of Intellectual disability and Schizophrenia upon admission.

Eight-Year-Old With Rumination Disorder: A Case Report and Literature Review

Poster Presenter: Akshay Lokhande, M.D., M.H.A.
Co-Authors: Swapna Deshpande, M.D., Ayesha Sattar, M.D., Humaira Abid, William Oliva

SUMMARY:

Rumination disorder occurs when patients effortlessly regurgitate food with subsequent spitting out or re-chewing and re-swallowing. Rumination was considered as a disorder affecting intellectually delayed infants or adults, with a prevalence rate ranging from 6 to 10 %. However it has become clear that cognitively unimpaired individuals can also have the disorder. There is very limited data available on the incidence and prevalence of rumination disorder. It is most often seen in the age group of 3 to 6 years of age, but the diagnosis is often delayed for months to years. Rumination disorder can present with halitosis, malnutrition, weight loss, growth failure, electrolyte abnormalities, dehydration, gastric disorders, upper respiratory tract disorders, dental problems, or aspiration pneumonia. The disorder is commonly confused with gastroparesis and gastroesophageal reflux disease. This case involves an 8-year-old boy who was referred to psychiatry for the evaluation and treatment of rumination disorder. Per parents, patient regurgitates food and then swallows it after every meal throughout his lifetime. He underwent extensive work up including esophagogastroduodenoscopy with biopsies, gastric empting study, and patch testing which were unremarkable. Multiple diets, medications and food restriction did not improve his symptoms. During evaluation, patient seemed to have co-morbid anxiety symptoms. Patient was started on Zoloft 25 mg titrated up to 50 mg in a week, and was referred for individual psychotherapy. Patient was scheduled for habit reversal therapy and diaphragmatic breathing. Upon follow up, patient showed partial improvement of his anxiety symptoms from his medications, which will help him to engage and participate in therapy. While the exact pathophysiology remains unclear, it is thought to occur due to a reversal of the esophagogastric pressure gradient. Diagnosis can be usually confirmed by high-resolution manometry or gastroduodenal manometry. Patients who present with rumination often have comorbid psychiatric conditions, with the most common being depression and anxiety. Acceptance of the diagnosis by family is essential for successful treatment because the mainstay of therapy.

Legalization of Marijuana and Its Impact on Attitude Among Youth Toward Use

Poster Presenter: Allen D'Souza, M.D.
Co-Authors: Senthil Vel Rajan Rajaram Manoharan, M.D., Tolga Taneli, M.D.

SUMMARY:

Introduction: Cannabis is the most commonly used illicit substance among adolescents. Marijuana use in youth has been linked with increasing difficulties in academics, psychiatric impairment, risky sexual behavior, increased alcohol consumption and motor vehicle accidents. Although recreational sale and use of cannabis is illegal in most states in the United States, a number of states have legalized it for recreational use. The intent of this literature review is to analyze the impact legalization of cannabis has

on attitude of youth towards use. Discussion: Studies in 2013 on college students in Washington and Wisconsin indicated that legalization would not change the participants' attitude towards use. Some students felt that legalization would mean an endorsement of marijuana and they were likely to perceive it as safe to use. Results from Monitoring the Future study shows a 20 percent increase in daily adolescent use of cannabis from 2005 to 2015. Another analysis on youth in Washington and Colorado by Cerda et al. shows that there was a decrease in perceived harmlessness and increase in Marijuana use by eighth and tenth graders following its legalization in Washington in comparison to other states without legalization however there were no significant differences noted in Colorado. Literature suggests that based on rates of tobacco and alcohol (which are legalized for adults) use in adolescents, legalization of cannabis for adults is likely to have an impact on its use by the youth. The factors by which legalization could possibly lead to increased use in adolescents are: decreased perceived risk associated with use, ready availability, lower cost price, and decreased fear of the law. Evidence already suggests that decriminalization leads to increased use of cannabis by adolescents. Increased parental use could indirectly increase use in youth. After the decriminalization of marijuana in 2010 in California a study revealed that 12th graders in California in comparison to their peers in other states were: (a) more likely to have used marijuana in the last 30 days prior to the study; (b) less likely to perceive use of marijuana as a health risk; and (c) less likely to disapprove of its use. Although some studies suggest that liberalization of laws with regard to cannabis might increase use among adolescents, some of the drawbacks of these studies are that they rely on self-reported use by adolescents and do not take into consideration adolescent populations outside of school. Conclusion: Further research is needed to clearly establish if legalization of cannabis for adult recreational use will increase its use among adolescents. However certain ways to prevent use among youth would be: imposing restrictions on sale of Cannabis to people under age of twenty-one, media regulations on advertising cannabis, adolescent substance use prevention program initiatives and educating youth about its negative effect in schools and colleges could help.

No. 20

Complexities in the Neurodevelopmental Presentation and Psychiatric Management of a Child With Multiple Inherited Chromosomal Abnormalities

Poster Presenter: Amandeep Jutla, M.D.

SUMMARY:

Objectives: We describe the case of a youth with inherited abnormalities in 3 chromosomes. The neurodevelopmental phenotype of this combination of abnormalities has not, to our knowledge, previously been described. Our case illustrates challenges in caregiver psychoeducation and clinical treatment particular to youth with inherited neurodevelopmental syndromes. Methods: The patient was seen following a referral to an intensive day treatment program at a large children's hospital. All available prior records were reviewed. Results: "E" was a 12-year-old girl referred to a day program for aggression at home and school. Mother was her primary caregiver, as parents separated when she was 7. At admission, E had diagnoses of ADHD, ODD, and intellectual disability (FSIQ 57). Her mother understood her to have "genetic abnormalities." Records indicated deletions in 2p25.1 and 5p15.33, as well as a duplication at 3q29. Prior testing showed that E's father had the same abnormalities. Her mother endorsed having "learning disabilities." Mother was observed to have cognitive limitations, concrete thinking, and was easily distracted. On physical exam, E had dysmorphic facies, microcephaly, astigmatism, oculomotor apraxia, and short digits bilaterally. Behaviorally she was impulsive and irritable, reportedly since early childhood; these symptoms improved only partially with stimulant medication. Given pharmacotherapy limitations, the focus of treatment was on psychoeducation and behavioral parenting strategies. Both proved challenging given mother's apparent cognitive limitations. At discharge mother reported better understanding the role of her daughter's genetic abnormalities in her behavior; yet, she continued to state challenges with following treatment recommendations, due to case complexity and cognitive abilities. Conclusions: The diversity of behavioral phenotypes across genetic syndromes are a challenge in psychiatric diagnosis

and treatment. Although E met descriptive diagnostic criteria for ADHD, ODD and intellectual disability, awareness of underlying genetic abnormalities contributed to our understanding of her limited response to medication and informed our work with her mother. As our understanding of the relationship between genotype and phenotype improves, psychiatrists will be better able to serve E and youth like her.

No. 21

Fluoxetine-Induced Behavioral Activation and Suicidal Ideation in a Pediatric Patient With Autism Spectrum Disorder

Poster Presenter: Amber Mansoor, M.D.

SUMMARY:

Introduction:Selective serotonin reuptake inhibitors are among the most commonly prescribed psychopharmacologic drugs, widely used to treat depressive disorders, anxiety disorders, and obsessive–compulsive disorder among children, adolescents and adults. However, they are associated with several serious adverse effects and pediatric population especially the ones with autism spectrum disorder (ASD) are more susceptible to developing them. This poster describes a case of 9-year-old patient with ASD and attention deficit hyperactivity disorder (ADHD) who was recently started on fluoxetine for anxiety and suffered severe side effects of increased aggression, impulsive/disinhibited behavior and suicidal ideation(SI). Case Report: 9 year old boy with history of ASD and ADHD-combined type was admitted to inpatient psychiatry pediatric unit for worsening physical aggression, SI and new onset of bizarre behavior for 2 weeks. Patient was recently taken off of ziprasidone on outpatient basis secondary to new onset hypertension and was started on fluoxetine10mg PO daily to assist with anxiety. 10 days into treatment with fluoxetine , patient was observed to experience severe mood swings and became physically aggressive at home. Patient's mother was also concerned about recent onset of disinhibited and odd behavior which included smearing food on the floor and eating it, feeding stuffed toys to the pet dog, attempting to cook without supervision setting off fire alarms in the house. Patient was also found to be endorsing SI with low self-esteem, seen by younger brother attempting to strangulate himself with a rope,one day prior to presentation. Patient had no prior history of suicide attempts. He was admitted to acute psychiatric care and fluoxetine was held on admission. Patient was continued on outpatient Guanfacine 1mg PO daily which was eventually up titrated to 2mg to assist with poor impulse control. 3 days into hospital course, patient improved drastically with complete resolution of SI and aggression. He was discharged to partial hospitalization program to ensure stability where he continued to show progress. He was discharged to home with well-controlled mood symptoms and behavior on Guanfacine 2mg PO daily. Discussion and Conclusion: This case is especially unique as it shows fluoxetine can induce multiple adverse effects in ASD patients. This patient's onset of symptoms coincides with timeline of initiation of the medication. Increased serotonin levels caused by fluoxetine may have resulted in over stimulation of this patient causing increased aggression, disinhibition and impulsivity leading to odd behaviors and exacerbation of SI. Abrupt resolution of symptoms farther suggests fluoxetine as the possible etiology. Clinicians must take special precautions when treating patients with ASD as these patients are more sensitive to medications. Initiation of a new medication at a low dose with slow up titration can prevent unfavorable outcomes.

No. 22

Trauma and Childhood Psychosis: A Case Study and Literature Review

Poster Presenter: Ananya R. Sreepathi, M.D.
Co-Authors: Ali Raza, Asghar Hossain, M.D.

SUMMARY:

A wealth of research shows a significant association between childhood adversities and the development of psychosis. Sexual abuse in particular seems to be strongly associated with the development of childhood onset psychosis. In our case report, an eight year old girl who allegedly suffered from sexual abuse suffered from psychotic symptoms leading to hospital admissions. The case is an example of the significant body of literature that shows a correlation between trauma and psychosis. By exploring this association we hope to create greater awareness

amongst providers and the community to screen for psychotic symptoms in children exposed to traumas, especially sexual traumas.

Mood Disorders of Childhood and Adolescence: How Can We Do Better?
Poster Presenter: Anshuman Srivastava
Co-Authors: Sean Reilly, Chiadikaobi Okeorji, Cheryl Ann Kennedy, M.D.

SUMMARY:
Background: Common risk factors for child & adolescent mood disorders include family psychiatric history, family dysfunction, exposure to early trauma, bullying, academic difficulties, and substance use. We investigated what risk factors were most prominent in our sample. Methods: We did a retrospective chart review of children & adolescents (6 to 18 years) diagnosed with a mood disorder (major depressive disorder, bipolar disorder, dysregulated mood disorder & unspecified mood disorder) who were evaluated at our University Hospital Psychiatric Emergency Service between November 2016 to July 2017. We collected demographics, health insurance access, family substance use, parental separation, trauma, bullying, school achievement, prior diagnoses, and family history of psychiatric conditions. Bivariate and multivariate analysis were done to examine associations between risk factor variables and a mood disorder diagnosis. Results: This analysis included 174 patients: 52% female; 44% African American, 33% Hispanic, & 4% white; Age: 47% 14-18 years, 30% 11-13 years, & 23% 6-10 years. Over 50% (93/174) had a mood disorder diagnosis. The mean age for mood disorder diagnosis was 13.56±2.85 years; mean age for non-mood disorder was 11.81±3.22; two tailed T-test analysis showed that there was a statistically significant difference at the level of p=0.05 between the mean age of those diagnosed with mood disorder and those with non-mood disorders. Bivariate association analysis showed that gender, age, family history of psychiatric illness, and exposure to trauma all are significantly associated with mood disorders. The risk ratios (RR) and p values of these are: Gender: RR=2.41, p=0.0045, Age – RR=4.08, p=.0019; Family History: RR=1.34, p=0.042, Trauma: RR=1.44, p=0.0219. Multivariate regression analysis confirmed their significance. The odds ratios (OR) & p-values for the variables were: Gender: OR=0.41, p=0.0091, Age: OR=2.55, p=0.0003, Family History: OR=6.85, p=0.0064, Trauma: OR=3.06, p=0.0136. The regression model with these variables had a constant with p-value of 0.0009. Conclusion: It has been well documented what risk factors play roles in childhood mood disorders, and this review confirms that these factors are strongly associated with mood disorder diagnoses in a community that struggles with a multitude of negative influences. This suggests that targeting mental health treatment, including trauma treatment, and substance use prevention and treatment in entire families, and not just in youngsters with a diagnosed disorder, may help moderate and assist families and providers with developing effective coping strategies and implementing therapeutic approaches.

No. 25
More Than Teenage Rebellion: Prodrome and Treatment of Anti-NMDA Receptor Encephalitis
Poster Presenter: Anushka Shenoy

SUMMARY:
This is the case of a 15 y/o Latina girl with no past psychiatric history who presented to the ED with violent, aggressive behaviors after several months of declining performance in school, erratic, unpredictable behavior, and non-epileptiform seizures. Her initial CSF was relatively benign (5 WBCs, 1 RBC, three oligoclonal bands) and MRI showed new lesion in the corpus collosum; as such, leading diagnoses were MERS vs conversion disorder until antibody studies sent to an outside lab revealed anti-NMDAr encephalitis. Prior to diagnosis, the patient's agitation became so severe that she required ICU admission, four point restraints, and developed rhabdomyolysis and an AKI. Her psychiatric symptoms were refractory to benzodiazepines, multiple second generation antipsychotics (olanzapine, quetiapine and ziprasidone), dexmedetomidine (though trial was limited by hypotension) before responding to scheduled valproate and several days of

immunosuppressive therapy. After two rounds of steroid treatment and IVIg, she was discharged on mycophenolate and monthly IV Ig infusions and seven months later has made a near complete recovery (ongoing symptoms include mild cognitive deficits and poor sleep), though she still takes daily valproate. While it is known that psychiatric symptoms of anti NMDA encephalitis are difficult to treat and that valproate acid has been used to treat affective symptoms (1, 2) well as in seizures (1), there are no published case reports of valproate successfully treating acute agitation and psychosis in this population. While it is theorized that antipsychotics (particularly first generation) can exacerbate symptoms by leading to EPS, it is also accepted that second generation antipsychotics are useful in managing psychiatric symptoms (1, 6); however, in this case her symptoms were not improved by administration of three different SGAs. This case exposes the potential use of valproate in treatment of acute psychosis in NMDAr encephalitis refractory to other psychiatric treatments. Second, this patient exhibited an approximately six month "prodromal" period of behavior and personality changes, gait changes, and non-epileptiform seizures prior to diagnosis with anti-NMDA encephalitis. While there are reports of pediatric patients (though typically <3 years old) presenting first with gait disturbances (4), there are few reports of "prodromal" symptoms prior to the acute presentation of this illness.

No. 26

Case Series: The Contagion Phenomenon: "13 Reasons Why" Inciting Suicidal Behaviors in Teenagers

Poster Presenter: Avaas Sharif, M.D.
Co-Authors: Gobindpreet S. Sohi, M.D., Sheema Imran, M.D., Avi Siwatch, Shabber Agha Abbas, Asghar Hossain, M.D.

SUMMARY:

Case Series: The Contagion phenomenon: "13 Reasons Why" Inciting Suicidal Behaviors in Teenagers. Co-Authors: Avaas Sharif M.D., Sheema Imran M.D., Gobind Sohi M.D., Avi Siwatch M.D., and Shabber Agha Abbas M.D. Abstract: Background: Suicide was the second leading cause of death in adolescents in America in 2016 behind only accidents. Each year over 1,000 teens die from suicide with four out of five of these cases having identifiable warning signs. This case series will explore 5 distinct cases within a one month span, within the same community hospital. The patient's all within the age range of 12-17 who either attempted suicide or had suicidal ideations with plan. "13 Reasons Why" the Netflix television series were self-reported as a major trigger by the families of each one of these individuals. Discussion: As we understand from the past, contagion is a phenomenon that is often correlated with suicide. We have seen suicide contagion within homes, schools, communities, and as social media figuratively makes the world a smaller place we are beginning to see suicide contagion over broader areas within this impressionable demographic. This case series will explore causality vs exponentiation of Suicidal ideation and attempts in teenagers as well as exploring similarities and differences surrounding these 5 cases.

No. 27

Theory of Mind Deficits in Adults With ADHD

Poster Presenter: Bernhard Kis, M.D.

SUMMARY:

Authors: Bernhard Kis, MD, Franziska Niklewski, MD, Georgios Ntoulias, MD, Nika Guberina, MD, Markus Krämer, MD, Isabel Dziobek, PhD, Jens Wiltfang, MD, Mona Abdel-Hamid, PhD. Objectives: Scientific results concerning social-cognitive deficits in adult patients with attention deficit hyperactivity Disorder (ADHD) are rare. Current research, however, detects an association between ADHD and deficits in social cogntion (Kis et al. 2017). Methods: Social-cognitive abilities were analyzed with the help of the Cambridge Behavior Scale (CBS) which assesses empathy. Theory of Mind was measured with the Movie for the Assessment of Social Cognition (MASC). In addition, executive functions were estimated with a series of well-established neuropsychological tests. We compared performance patterns of treatment-naïve adults with ADHD (n=30) with a healthy control group (n=30). Basic demographic measures were matched. Results: In comparison to the healthy control group, adult patients with ADHD scored significantly lower in empathic performance in the CBS (p= 0,03).

Regarding Theory of Mind abilities, we observed that in the group of adults with ADHD the response option reflecting a "missing Theory of Mind" was chosen significantly more often (p=0,04). However, results of control questions evaluating attentional skills also showed a poorer performance in adults with ADHD (p=0,015). Conclusion: ADHD is associated with deficits in Empathy and Theory of Mind. This findings complete our knowledge about deficits in Social Cognition in adults with ADHD. Further research should focus on replication in larger study samples.

No. 28

Suicide Contagion: Our Responsibility as Mental Health Clinicians

Poster Presenter: Bimla Rai, M.D.
Co-Authors: Ketan A. Hirapara, M.B.B.S., Tolga Taneli, M.D., Nicole A. Guanci, M.D.

SUMMARY:

BACKGROUND: A recent World Health Organization report [1] shows that suicide is the 17th leading cause of death globally and the second leading cause of death among 15 to 29-year-olds, signifying it as a public health problem. Suicide attempts are usually preceded by suicidal ideation (SI). As per literature, over 90% of youth who die by suicide have psychiatric disorders, [2] emphasizing the importance of vigilance in suicidality assessment. In modern society, use of media plays an important role not just in communicating or connecting with others, but also possibly increasing suicidal risk in certain vulnerable populations by copycat effect, e.g. by portrayal of suicide. [3,4] Here, we present two cases of reported suicidal ideation resulting from watching a Netflix TV series on suicide. CASES: Case 1: A 13 year old female with history of Major Depressive Disorder (MDD) was referred for emergency evaluation by her school for SI. The patient's mother was called after the patient wrote a statement that she wants to kill herself by cutting her wrist. This note was found by her classmate, who alerted the school counselor. The patient also had recorded an audio tape a few days earlier, reporting her four friends' names whom she would hold responsible for her decision to kill herself. The patient was diagnosed with MDD two years earlier and her depressive symptoms were in partial remission with psychotherapy alone. Case 2: A 15 year old female with history of MDD and Generalized Anxiety Disorder was referred from school for an emergency evaluation of SI. She repeatedly made statements that she plans to kill herself by cutting her wrist. The patient's psychiatric symptoms were in partial remission with Zoloft 100 mg daily and weekly psychotherapy. Despite in clinically stable state in respect to their illness, both patients developed SI abruptly. There were no proximal psychosocial stressors; however, both reported recently watching the Netflix TV mini-series 13 Reasons Why, which most likely had promoted suicidal thoughts and promoted the means.[5] DISCUSSION: No doubt media has many positive attributes, but some negative impact and suicide contagion - well documented since 1986 - can be very concerning in society as evident from our cases. Since it serves as an essential platform to communicate with mass audiences and is ubiquitous, behavior modification and awareness are the most likely useful strategies that need to be adopted. Risk reduction measures that can be implemented by parents, counselors, and providers include guidance on media use by youth, close monitoring and discussion about suicidal content as portrayed in media, identifying risky behaviors, and encouraging enrichment activities (such as the outdoors). Due to the interface between mental health and this emerging concern, psychiatrists play an important role in screening for suicidality, but further societal awareness is needed as media attitudes to suicide portrayal change.

No. 29

Prevalence of Posttraumatic Stress Disorder in Student Whose School Burned Down

Poster Presenter: Chawanun Charnsil, M.D.

SUMMARY:

Background: Posttraumatic stress disorder (PTSD is a mental disorder that can develop after a person is exposed to a traumatic event, such as sexual assault, warfare, traffic collisions, or other threats on a person's life. Symptoms may include disturbing thoughts, feelings, or dreams related to the events, mental or physical distress to trauma-related cues, attempts to avoid trauma-related cues, alterations in how a person thinks and feels, and increased

arousal. Furr, Corner, Edmunds, and Kendall (2010) conducted a systematic review and meta-analytic examination of 96 identified youth PTSD studies following natural and human-made disasters. These reviews indicated that children show symptoms most in the first year post-disaster, and the symptoms mostly decrease rapidly (Furr et al., 2010; Wang et al., 2013) by nine to 14 months post-disaster (Vogel & Venberg, 1993). In Thailand there is a constant increase in human made disasters. The school that we want to study is a primary school in the rural area. Some students live at school dorm that burned down.Seventeen students died in the disaster. We want to know how much this disaster affects the remain students. Aims: This research aims to examine prevalence of posttraumatic stress disorder and its related factors in student whose school burn down, one month and six months after the incidence. Methods: Student in grades 1-6 were invited by asking permission from their parents. Subjects whose parent gave consent were screen PTSD by using UCLA PTSD Reaction Index(DSM-5 Version) at 1 month and 6 months after school burn down. Before screening, UCLA PTSD Reaction Index (DSM-5 Version) was translated to Thai and back to English to confirmed accuracy.Children who were diagnosed with PTSD were interviewed by child and adolescent psychiatrist to confirm diagnosis. Percentage and logistic regression were use as statistic evaluation. Results: Fifty-six students were invited to participate in this research with their parent's approval. Five out of fifty-six students (8.9%) had PTSD at one month after incidence. Two of them had symptoms recovered after six months. Six out of fifty six students (10.7%) had PTSD at six months after the incident, three out of six developed symptoms after one month, with the female-male ratio at 2:3. Students who lived in dorms when it burned down had significantly more PTSD than those who didn't live there $p<0.01$, RR=5.16(4.04-6.6). The age and history of facing disastesr or traumatic experience were not difference between group. Conclusion: Post-traumatic stress disorder is a common disorder in children after a disaster. Although some can recover shortly after incidence there others who develop symptoms one month after the incident. Direct exposure to trauma is a risk factor that can lead to the development of PTSD.

No. 30

Gender Specific Manifestations of Conduct Disorder in the Female Adolescent Patient

Poster Presenter: Crystal D. Reyelts, M.D.

SUMMARY:

LM, a 15 year old Caucasian female with past psychiatric history of post traumatic stress disorder (PTSD) and disruptive mood dysregulation disorder (DMDD), presents to the child and adolescent inpatient psychiatric service for worsened urges of hurting and killing animals. The patient had endorsed killing hamsters and birds for the past three years. She had not told anyone about her killing of animals until her psychiatric hospitalization. Although she endorsed not wanting to hurt animals, the patient reported that killing animals allowed her to feel empowered and in control. The patient reported that her feelings of power were brief and this is why she continued to hurt other animals over multiple years. On admission, patient endorsed thoughts of hurting other people but she denied homicidal ideation, suicidal ideation or self harm thoughts. Of note, patient also had history of PTSD due to two past episodes of sexual assault and reported verbal abuse from mother. She also reported persistent irritable mood along with verbal outbursts towards her mother which meet diagnostic criteria for DMDD. Due to her presentation at admission of killing animals, a thorough psychiatric evaluation was necessary to determine if patient also meet diagnostic criteria for conduct disorder (CD). Although the prevalence of CD has been found to be up to ten times higher in males than in female, it is still a common disorder in adolescent females. In this poster, we discuss differences in the presentation of and risk factors for CD between males and females. We will also discuss neuroimaging evidence for a pathophysiological basis between male and female presentations of CD.

Consultation-Liaison Psychiatry in a Pediatric Setting: An Argentinian Experience

Poster Presenter: Jaime Mario Kuvischansky, M.D.
Co-Authors: Leonardo Hess, Julia Javkin, Romina Martinangeli, Antonela Nasello, Corina Ponce, Ezequiel Rodenas, Carla Graziadei, Pablo Bassanese,

Javier Monaco, Manuel Francescutti, Maria Jimena Matacin

SUMMARY:
Introduction: The steady rise in psychiatric consultation noticed in our country in the last few years, frequently related to drug use disorders, suicidal behavior and its clinical consequences, made a major need of developing a consultation-liaison psychiatry service, specifically to work in a pediatric setting. It must be remarked that before doing a pediatric consultation the psychiatrist needs to understand the context, including the general medical condition and its prognosis. Objective: Illustrate our experience in liaison psychiatry with this particularly sensitive population. It also tends to describe the most frequent chief complaints and the psychiatric approach chosen. We used specific algorithms to give the most accurate and actualized treatment to this population. Methods: This is a descriptive study, based on a population composed by children under 18 years old admitted in "Sanatorio de Niños" (Childs Hospital), Rosario, Santa Fe; Argentina between January 2015, and July 2017. Data was collected from medical records and analyzed with GraphPad v5.0. Results: During this period 58 patients were treated, 38 were women and 20 were men. The age range was from 5 to 18 years old. Only 16 were on previous psychiatric or psychological treatment. The most common reasons for consultation were: drug intake in the absence of suicidal behavior and nonsuicidal self-injury. Only 7 patients received psychopharmacological treatment during this stage. Only 3 patients received indication of a psychiatric hospitalization, and 55 continued outpatient treatment. Conclusion: This study shows our experience in the consultation in a pediatric setting. The findings prove the importance of an early detection of any sign or symptom that suggests mental illness, to give specific and specialized treatment. It is also remarkable the importance of keeping safe and away of children any medication to prevent serious consequences.

No. 32

Social Functioning and Occupational Adjustment Level Aqmong Patients With Schizophrenia Spectrum Diagnosis

Poster Presenter: Jaime Mario Kuvischansky, M.D.
Co-Authors: Romina Martinangeli, Leonardo Hess, Julia Javkin, Carla Graziadei, Antonela Nasello, Maria Jimena Matacin, Manuel Francescutti, Javier Monaco, Ezequiel Rodenas, Pablo Bassanese

SUMMARY:
Introduction Schizophrenia is a chronic disease that has a progressively deteriorating course that affects multiples areas. The average prevalence of this disease is of 1% among the general population. The aim of this article is to describe the labour integration, the level of autonomy and the chances this population has to achieve social development. Furthermore this investigation tends to illustrate the impact that this situation has on the patient and his family. The purpose of this investigation is to provide information to allow specific medical approach. Methods This study includes 51 patients with schizophrenia diagnosis (Diagnostic and statistical manual of mental disorders, 5th edition; 2013), 22 were women and 29 were men. All the patients were receiving outcome treatment at a medical center in Rosario city. The data was collected from medical records from January 2014 to January 2016 and analyzed with Microsoft Excel.
Results/Conclusion Most of the patients were unemployed. Those who could ensure a work opportunity was at the expense of a family business venture. The level of autonomy was limited in most cases. These results reflect the environmental impact of schizophrenia, affecting social, family and economic sphere.

Drug Intake Beyond Suicidal Behavior: A Study in Pediatric Patients

Poster Presenter: Jaime Mario Kuvischansky, M.D.
Co-Authors: Antonela Nasello, Leonardo Hess, Maria Jimena Matacin, Romina Martinangeli, Carla Graziadei, Ezequiel Rodenas, Julia Javkin, Javier Monaco, Julia Javkin, Manuel Francescutti

SUMMARY:
Introduction Suicidal behavior includes a wide spectrum: from the ideation, development of a plan and a method of acquiring the means to do so until the possible consummation of the act. The suicide attempt is defined as any act in which an individual cause himself injury, or damage (variable) regardless

of the mobile and the result is lethal or not, in order to die. Drug intake is the method most frequent used, however it is not always used as a suicidal behaviour. Methods This is a prospective and descriptive study; the populations included were patients with a drug intake no matter the aim of the consumption. The data were collected during 12 moths using two questionnaires, one during the admission and the other one during the following. The data collected were analyzed with GraphPad v5.0 software Results This report shows several differences among the social-demographic groups; illustrate the risk factors and the different medical approach. Increased risk for further attempts. They increase the chances of clinical complications. Increased risk for medical complications. There are not standarized methods for evaluate risk. Most frequent in adolescents. Nonsuicidal self-injury (NSSI) might promotes similar behaviours among their peers. Irrational use of medications is a risk factor. Conclusion These results reflect the importance of an accurate prescription of drugs. This study presents characteristics of self-injurious behaviours in the absence of suicide attempt. These behaviours are considered an aggravating factor for the patient's progress. This study provides useful results for further investigations.

No. 34

Schizo-Obsessive Disorder

Poster Presenter: Frederick Afari

SUMMARY:

1. Introduction Obsessive compulsive disorder (OCD) is considered to be closely related to anxiety disorder, per DSM-V; obsessions are defined as recurrent and persistent thoughts, urges, or images that are experienced as intrusive and unwanted, whereas compulsions are repetitive behaviors or mental acts that an individual feels driven to perform in response to an obsession or according to rules that must be applied rigidly. On the other hand, DSM-V explains schizophrenia as having abnormalities in one or more of the following five categories: delusions, hallucinations, disorganized thinking/speech, grossly disorganized or abnormal motor behavior and negative symptoms. Although, these two disorders have been individually recognized in DSM-V, no reference is made as to the relationship between OCD and schizophrenia.

No. 35

A Case of Delusional Parasitosis With Prodromal Alcohol Abuse

Poster Presenter: Gargi Patel, M.D.
Co-Author: Nancy Kerner

SUMMARY:

Background: Delusional Parasitosis (DP) is a rare psychiatric disorder, in which patients have fixed false belief that their bodies are infested with small pathogens. The initial psychiatric diagnosis is often based on the exclusion of organic causes. By the time patients are referred for psychiatric evaluation, they already have had significant function decline; in severe cases, patients are impaired globally and lack capacity for self-care. While treatment of DP has been the focus, psychiatric warning signs in the prodromal stage receive little attention. Here we present a case of DP comorbid with alcohol abuse. Case Presentation: the patient is a 61-year-old woman, single, childless, retired physician, lives alone in NYC with no formal psychiatric history, who presented to ED with c/o leg swelling and skin infection with flies and fly larva. She provided a huge photo collection of her stool and nasal mucous tissue and claimed that they were infested. She firmly believed that she suffered from a condition called myiasis, although laboratory workups from different medical providers showed no evidence of infestation. She received a psychiatric evaluation in the ED, which revealed that she had a history of episodic alcohol and cannabis abuse for many years and increased a significant amount of alcohol intake for the past 6 months. She explained that the renovations were started in the apartment above hers 6 months ago and many small flies came into her apartment and began to lay larvae in her body. This led to her abusing laxatives to cleanse her GI tract, causing her significant weight loss, moving out of her apartment into hotels, and treating the infested skin with topical medications. Although she acknowledged that myiasis was primarily only seen in a tropical environment, but felt that her case was "unique." She expressed significant stress and stated, "No one believes me, but I have been suffering!" Collateral from her family confirmed that

the patient had gradually lost her ability for self-care along with increasing alcohol intake. The patient was admitted to inpatient psychiatric care involuntary for 3 weeks. She was treated with risperidone 4mg daily. Upon her discharge, she was no longer delusional and did not have a desire to drink alcohol. During the 3 months of outpatient psychiatric treatment, risperidone was decreased to 2mg daily. She initially attended weekly therapy, but slowly returned to drinking alcohol for "anxiety". She eventually left treatment and was unreachable. Conclusion: DP is a serious psychiatric disorder with rapid function decline in previously high function middle-aged and older individuals. Identification of prodromal symptoms (e.g., substance abuse, anxiety, and mood disturbances) before DP is fully developed has an important clinical implication. Treatment of comorbid psychiatric conditions is equally critical as treatment of DP to prevent relapse and recurrence.

No. 36

Decrease of Relapses in Long-Term Medicated Schizophrenic Patients

Poster Presenter: Gema Medina Ojeda
Co-Authors: Claudia Noval Canga, Adrián Alonso Sánchez

SUMMARY:

INTRODUCTION Long acting medication has been a massive advance in schizophrenia and schizoaffective disease treatment helping those patients with bad previous adherence. Nonetheless, adverse effects such as prolactin serum levels increase or metabolic syndrome have been reported. OBJECTIVES Observe clinical and psychopathological long term evolution of patients treated with Long term injectables, including Paliperidone, Aripiprazole and Zuclopentixole. METHODS Each 6 months blood tests with metabolic parameters and weight measures have been done to the patients included in this study. Also psychopathological and live quality scales have been fulfilled half-yearly. All people included in this study were psychopathologically stable at the moment of recruitment. RESULTS None of the — patients included in this study missed any of the injections, showing a better pharmacological and therapeutical adherence compared to oral medication. Up to this date, none readmission nor severe relapse has been reported in any of the patients. This stability seems to be related to life quality improvement reported in the scales. Weigh gain has been the most evident adverse effect, with an average increase of — kilograms. Moreover, mild prolactin serum levels increase has been detected, especially in those treated with Long term Paliperidone, with low clinical impact. CONCLUSIONS Long term antipsychotic medication continues being one of the best tools to deal with bad adherent patients. As some mild adverse effects may appear, close clinical observation is needed in order to preserve patients' clinical health.

No. 37

Delusions of Self Accusation in a Sexual Abuse Victim

Poster Presenter: Hajra Ahmad

SUMMARY:

This case report is clear depiction of the devastating aftermath of sexual violation in an individual. We present a case history of an individual who presented with delusions of self accusation. He had fixed delusions of being a sex offender and a murderer and had called the authorities many times and turned himself in. Since no proof was found against him he was released on bail but was registered as a sex offender. His fixed delusions seemed to have stemmed from his extremely abusive childhood and adolescent memories. He felt the need to be punished and had extreme feelings of shame, guilt and inability to make social interactions. From this case we try and understand the extreme psychological trauma of the victims, their negative self-imagery and the dysfunctional coping methods that these individuals adopt in their adulthood. I chose this case because this case also brings our attention to male survivors of sexual abuse as this is not as widely discussed topic as female sexual abuse. It not only shows patient's distorted relationship with others but also with himself. As mental health professionals we should strive to find more effective ways to bring these individuals back to the normal life through a combination of medications and therapy.

No. 38

How to Safely Prescribe Antipsychotic Drugs During

a Pregnancy

Poster Presenter: Hema Mekala
Co-Authors: Simrat Sarai, Steven B. Lippmann, M.D.

SUMMARY:
The prevalent use of antipsychotic medication has increased rapidly. Among pregnant women, up to about one third are prescribed antipsychotic pharmaceuticals during gestation. These drugs commonly provide efficacy for people with psychoses, bipolar disorder, affective illness, or anxiety. Pregnant women with untreated psychiatric conditions are at greater risk for symptom relapse and that increases maternal and child morbidity rates. It raises the chances for bleeding, abnormal placental development, and/or eclampsia, as well as for substance abuse and for inadequate prenatal care. Treating women with emotional illnesses during a gestation requires extra care since antipsychotic medicines could induce teratogenicity in newborns. Nevertheless, when clearly indicated, haloperidol or second generation antipsychotic pharmaceuticals like quetiapine, risperidone, or olanzapine are commonly the preferred pharmacotherapy during a gestation. There is evidence that the fetal malformations are not significantly increased when pregnant women are prescribed antipsychotic medications, as compared to those not exposed. Of course, these drugs are not consistently safe nor effective during pregnancy; each case has its own individual risk-to-benefit ratio. Nevertheless, when appropriately indicated, prescribing antipsychotic medication during a gestation should facilitate better obstetric, neonatal, and psychiatric prognoses. It is important to advise pregnant women experiencing a significant mental illness regarding consistent medication and prenatal vitamin intake and about obstetrical and psychiatric follow-up. Guidance about diet and not smoking, using drugs, or taking non-indicated medicines is also advantageous.

No. 39

Worsening Depression After Treatment of "Pleasant" Psychotic Symptoms: A Case Report

Poster Presenter: Jaison Josekutty Nainaparampil, M.D.
Co-Author: Richard Calvin Holbert, M.D.

SUMMARY:
Introduction: Schizophrenia and its related disorders significantly decrease quality of life. Patients have impaired interpersonal relationships, diminished educational attainment, lessened occupational functioning, and worse medical health than those without the disorder. The disorder is characterized by delusions, hallucinations, disorganization, negative symptoms and cognitive symptoms. Auditory hallucinations are usually ego dystonic for patients. They can disrupt one's ability to stay focused on reality and can increase the risk of suicidal ideation. However, case reports by Siris et al. discuss two patients whose positive psychotic symptoms may have decreased their suicide risk. In this case report, we will discuss a patient with ego syntonic auditory hallucinations that led to severe disorganization putting them at risk of self-neglect and when resolved with treatment led to hopelessness and suicidal ideation. Case Presentation: The patient is a 50-year-old Caucasian male suffering from schizoaffective disorder, bipolar type. Co-morbidities include alcohol use disorder, severe and cocaine use disorder, severe. The patient presented with various delusions. He believed he was the reincarnation of Jesus, a "sun god," and a man who could speak telepathically to his nine wives. He felt that others were jealous because of his "powers." The patient expressed to staff that he "enjoyed" his auditory hallucinations. Because he was resistant to prior neuroleptics, the patient was started on clozapine during his psychiatric admission. While the medication was titrated, the patient's delusions and auditory hallucinations began to subside, and the patient was then seen to endorse depressive symptoms including suicidal ideation. He reported that he felt "lonely" when his voices left him. Discussion/Conclusion: This case raises several questions about the proper way to assess a patient's psychotic symptoms. There are already categories that organize auditory hallucinations into "command" or "conversing," but it is not as common to categorize these symptoms into "pleasant" or "non-pleasant." Doing so may yield further insight into a patient's suicide risk. Additionally, clozapine is an agent that has been shown to be protective against suicidal behavior. Although clozapine's side effects may have contributed to this patient's worsening mood, the

patient only suffered from mild constipation and sedation. The qualitative content observed in our patient may suggest exceptions to the finding that clozapine is associated with the alleviation of depressive/suicidal symptoms.

No. 40

Treatment Challenges With Psychosis-Induced Catatonia

Poster Presenter: Tarek Kanaa, M.D.
Co-Author: Tayyaba Ali

SUMMARY:

The patient is a 31 years old Hispanic male with unknown past psychiatric history presents to the hospital as an Emergency Detention (ED) for bizarre behavior. Per records that arrived with the patient, he was witnessed to be sitting on a bus bench for hours before attempting to get onto a bus. Patient current state in the hospital ER lobby made it difficult to assess the patient as he would not speak or interact. Records from the Crisis Center indicates that the patient has been minimally responsive and had not been eating or drinking for the past few days. A phone call to the patient's parents reveals that the patient moved from North Carolina to Houston for employment, but he has a history of being on medications and has had episodes in the past where he stops communicating. A concern for catatonia is strongly considered at this time. However, his catatonia presentation was not classic as he was able to move and follows orders with prompting. The patient was started on Zyprexa Zydis and Ativan. In this poster, we will discuss the difficulties and challenges in treating mutism catatonia in a patient with poor previous records of psychiatric illness.

No. 41

Efficacy of Adjunctive Loxapine in Clozapine-Resistant Schizophrenia

Poster Presenter: Umang Shah, M.D., M.P.H.
Co-Authors: Lauren Diefenderfer, Jianwei Jiao, M.D., Ph.D.

SUMMARY:

Clozapine has been widely accepted as the most effective treatment for schizophrenia, refractory to other antipsychotic drugs, which comprise of about 25% to 30% of patient population. However, a significant portion, 45 to 70%, of clozapine-treated patients show a partial or inadequate response to treatment. There is scarcity of established evidence to guide clozapine-resistant psychosis in patients with schizophrenia or schizoaffective disorder. Several augmentation strategies including addition of another antipsychotic, mood stabilizers, anxiolytics, antidepressants, and glutamatergic agents, have failed to demonstrate convincing efficacy. Some data suggested promising efficacy of adjunctive ECT, however its clinical application cannot be generalized. The treatment of this subgroup of patients remains a major challenge, with increased health care costs and poor quality of life for affected individuals. Current data suggests that with similar efficacy to the other antipsychotics, loxapine, a dibenzoxazepine tricyclic, acts like a second generation antipsychotic at lower doses, but has an adverse effect profile comparable to that of the first generation antipsychotics at higher doses for chronic treatment. A clinical trial observed improvements with adjunctive treatment with loxapine for patients with refractory psychosis, insufficiently responsive to clozapine alone with no effect of loxapine on plasma clozapine levels. This is a case discussion about a 24-year-old African-American woman, non-smoker, diagnosed with schizophrenia and benign ethnic neutropenia. Patient has a long standing history of auditory, visual and tactile hallucinations, poorly controlled with multiple antipsychotic regimens including an ECT course. Her medications included adequate trials of fluphenazine, fluphenazine decanoate, haloperidol, haloperidol decanoate, lurasidone, paliperidone, paliperidone palmitate, risperidone, ziprasidone, quetiapine, olanzapine, and aripiprazole in various combinations. Divalproex and lithium were used as augmentation agents; however, she continued to exhibit psychotic symptoms that hindered her capacity for self-care, performing ADLs and interacting socially, for several years. The patient was started on clozapine for resistant psychosis, which helped improve her hallucinations for brief period of time before she gradually decompensated again. A trial of loxapine as an adjuvant therapy was planned. Within a week of tolerating adequate dose, patient's symptoms have improved significantly. This was evident by Global Clinical Impression, BPRS

scores, group attendance, and self-care. She has been performing ADLs independently, including hygiene and grooming. As we continue to monitor her symptoms with a hope of continued stabilization, her current improvement in quality of life, provides a rationale to further explore the efficacy of combining clozapine with loxapine for treatment resistant psychosis.

No. 42

Management of Lithium Toxicity in a Patient With Multiple Medical Comorbidities

Poster Presenter: Salman N. Salaria, M.D., M.P.H.

SUMMARY:

Lithium toxicity can result in patients who are on lithium therapy and have predisposing factors (ex: dehydration). The importance of this case report is to highlight the necessity to narrow down a broad differential diagnosis in an individual that presents with lithium toxicity with multiple medical comorbidities. Effective and efficient management are crucial in the prevention of future toxicity. Methods of practice which increase the awareness and knowledge of lithium toxicity among health care professionals and patients will help prevent lithium toxicity in patients on lithium therapy. With this protocol in mind, lithium can effectively stabilize individuals with a mental illness that will require its therapeutic effects for the entirety of their lives.

No. 43

Managing and Discharging a Case of Treatment-Resistant Schizophrenia With a History of Arson

Poster Presenter: Salman N. Salaria, M.D., M.P.H.

SUMMARY:

This is a case report on Mr. X, a 47 year old African American male with a diagnosis of treatment resistant schizophrenia. Mr. X has had a previous history of several hospital admissions in the past, starting from the early 1990's due to his mental illness. Client's legal history includes a charge of arson in the third degree. Mr. X had been prescribed several different psychotropic medications which include olanzapine, risperidone and quetiapine with little improvement. His most recent medication protocol before his discharge included clozapine, haloperidol decanoate and lithium. The importance of this case report is to investigate the link between schizophrenia and arson and to also stress the hurdles that are faced by health care workers when finding adequate long term placement for these individuals; once they are stable enough to be discharged into the community.

No. 44

Schizophrenia in Transitional Age Youth: Challenges in Diagnosis and Access to Services

Poster Presenter: Vanessa Schmidt, M.D.
Co-Author: Meelie Bordoloi, M.D.

SUMMARY:

INTRODUCTION: Schizophrenia is a neurodevelopmental disorder manifesting usually in late adolescence or early adulthood causing significant dysfunction. Psychotic symptoms may be common in children but diagnosis of schizophrenia rare. Diagnosis may be difficult with co-morbid substance use. Being a rare disorder in childhood comes with its own challenges with access to appropriate services, availability of medications covered by insurance especially for patients who have a history of non-compliance. CASE STUDY: X is 17 year old AA male who presented to the inpatient unit with bizarre behaviors. He believed that he was a famous rapper and had a UDS positive for THC. He was on aripiprazole, citalopram and trazodone but stopped 1 week ago after release from the Department of Youth Services after successful completion of substance abuse treatment and had been in their care for 7 months. During his 1 week hospitalization he was restarted on home medications with resolution of his symptoms. On follow up in clinic he was non-compliant with his medications, started having strange behaviors like talking to self and trees, laughing inappropriately, knocking on neighbor's doors and was hospitalized. His UDS was again positive for THC. He was referred to substance use Rx and after reaching the facility patient eloped. Family contacted outpatient provider informing that patient was non-compliant with medications, substance use treatment and he could not be located. Months after the elopement, the patient was arrested for attempting to steal a car and was incarcerated. He stayed in jail for about 4 months and after his release was hospitalized. During his incarceration he was off medications and

was in solitary confinement. After being released, he didn't recognize his mom. Upon admission he was paranoid and believed soap, food was poisoned. He had minimal interaction and was responding to internal stimuli. He would be sexually inappropriate and requested discharge to his "wife." Given his noncompliance, team believed he would do better with a long acting injectable. He had done well on oral aripiprazole and team decided to try LAI but given his age insurance would not cover it. He was the started on a trial of oral Haldol and slowly transitioned to Haldol-D. After 5 weeks he started to doing better but was not back to baseline. A diagnosis of Schizophrenia was made based on history and evaluation. One month after discharge he was readmitted a few days prior to his next Haldol D injection. He was getting agitated and bit his mother and sibling. He was pacing and more anxious and disliked being alone. His dose of his Haldol D was increased and he was discharged because of some improvement in symptoms. DISCUSSION: First break schizophrenia may occur during adolescence. Providers working with transitional age youth with diagnosis of schizophrenia also continue to struggle with problems such as non-compliance, lack of wraparound services for patient and family.

No. 45

Relationship Between ANKK1-Taq1a Polymorphism, Overweight and Executive Dysfunction in First-Episode Psychotic Patients: A Controlled Study

Poster Presenter: Vanessa Sanchez-Gistau
Co-Author: Sara Arranz

SUMMARY:

BACKGROUD: overweight observed in schizophrenia and the subsequent risk for developing the metabolic syndrome is a major concern in the treatment of psychosis. It has been reported overweight rates to 48.3% in first episode patients (FEP) treated with antipsychotics for less than 6 months. Consequently, it has been suggested that tendency to become overweight is related not only to antipsychotic treatment itself but also to the interaction with other environmental and genetic factors present from the illness onset. Cognitive deficits are one of the core symptoms of schizophrenia and executive dysfunction has been also implicated in the pathogenesis of obesity.The A1 allele of the ANKK 1-taqIA polymorphism modulates the density of D2 receptors in the striatum and has been associated with both schizophrenia and obesity. It is controversial the nature of this association but there is some evidence of a relationship between the presence of A1 allele and poorer executive function performance in both schizophrenia and obesity. However, any previous study has investigated the interaction of overweight, executive dysfunction and taqIA polymorphism in incipient psychotic patients METHODS: We included 116 outpatients with an incipient psychotic disorder , 78 FEP with antipsychotic treatment of less than 3 months and 36 At risk mental state (ARM) attending the Early Intervention Service of University Hospital, Pere Mata Institute of Reus, Spain. Total DNA was obtained from the peripheral blood and the rs1800497 variant was genotyped. All subjects underwent executive function assessment by means of parts A and B of trail making test (TMT), the interference score of the Stroop test and the Wisconsin Card Sorting test (WCST). A set of ANCOVAS were performed to determine the effect of the interaction of overweight and allele status on executive function after controlling for confounders. RESULTS: Mean age of the sample was 24.4 (5.16) years and 67.7% were males. Nearly 30% showed a BMI higher than 20 and 67.5% were on antipsychotic treatment. No differences in chlorpromazine equivalent dose of antipsychotics were found between overweight and non-overweight patients. Two-way ANCOVA revealed a significant main effect of group status (F= 7.42; p= .008) and interaction effect group x allele status (F= 4.77; p =0.032) in the interference measure of Stroop. CONCLUSIONS: The overweight A1 carriers performed worse than A1-non carriers, whereas among non-overweight no differences were found in executive function performance. Although limitations, these findings suggest new evidence about the contribution of a gene involving dopamine control in weight gain via executive dysfunction in psychotic patients. Identifying psychotic subjects at higher risk to develop metabolic syndrome can help clinicians to promote preventive and intervention-based measures in the multidisciplinary treatment of psychosis.

Mystery of Auto-Enucleation: What Is Behind the Eye?

Poster Presenter: You Na P. Kheir, M.D.

SUMMARY:

Mr. C is a 20-year-old African American male with a previous history of schizophrenia and history of multiple suicide attempts who presented to hospital for evaluation and management of self-inflicted enucleation of his right globe. He was initially seen at a local psychiatric emergency room and was placed on an involuntary commitment due to his psychosis and unwillingness to be hospitalized. While he was waiting, he complained of eye pain with concern for conjunctivitis. While waiting for medical clearance for transfer, the patient entered the bathroom without supervision and exited after he removed his right eye. He told the staff that he was simply scratching his eyes. He required immediate medical transfer to stabilize his condition and subsequent surgical intervention to clear the right orbit of the remaining nonviable tissue and repair laceration of his left eye. He was subsequently hospitalized psychiatrically and during hospitalization, Mr. C received a prosthetic replacement of right eye, as well as a prostatic cap to make the eye look more natural. He was stabilized on olanzapine, but he was mostly guarded with restricted affect, requiring a prolonged one-on-one monitoring while in the unit. He refused to discuss why he removed his eye or how he felt at that time, and he demonstrated limited insight about the episode. In this poster, we discuss the several hypotheses on causes and risk factors of auto-enucleation and cross-cultural implications of auto-enucleation in psychiatric disorder.

No. 47

Diabetes Care in Schizophrenia: What Results in Better Care?

Poster Presenter: Jonathan Hsu, M.D.
Co-Author: Paul Kurdyak

SUMMARY:

Introduction: Individuals with schizophrenia have high rates of diabetes and receive poor care. Diabetes guidelines, based on high quality evidence, suggest that optimal diabetes care includes periodic HbA1C, eye and cholesterol testing. Little is known about what determines the diabetes care quality within this population. Objective: Investigate the factors which impact diabetes care quality in patients with schizophrenia. Methods: A retrospective cohort study of Canadian administrative health records in individuals aged 18 or older with schizophrenia and diabetes on April 1, 2011 who reside in the Province of Ontario. Patients were divided into groups depending on how many of the three guideline-concordant diabetes care procedures they received in a two-year period. Optimal care was defined as having all three of the following in a two-year period: 4 HbA1C tests, 1 eye test and 1 cholesterol test. Demographic, clinical and service utilization characteristics were compared across three levels of diabetes care (0 vs. 1, 2, or 3 diabetes tests received) using multinomial logistic regression odds ratios. Results: Among 26,259 individuals in the Province of Ontario, Canada with diabetes and schizophrenia, 4019 (15.3%) had none, 7506 (28.6%) had one, 8378 (31.9%) had two and 6356 (24.2%) had all three diabetes care tests which consists of 4 HbA1C testing, 1 eye testing and 1 cholesterol test in a 2-year period from the index date. The overall number of primary care visits was not associated with diabetes care quality. However, primary care visits for non-mental health reasons only was strongly associated with better care [0 vs. 1 OR 2.68 (95%CI 2.38-3.01), 0 vs. 2 OR 4.50 (95%CI 4.00-5.10) and 0 vs. 3 OR 6.37 (95%CI 5.51-7.36), p-value = <.0001]. In addition, more outpatient psychiatrist visits were associated with better diabetes care and an increased number of psychiatric hospitalizations was associated with worse diabetes care. Conclusions: The results suggest that primary care physicians who focused on the medical issues of our schizophrenia population provided better care, whereas those focused on psychiatric issues were less likely to adhere to diabetes quality guidelines. The pattern may be suggestive of “diagnostic overshadowing”, where health care providers emphasize psychiatric illness issues to the detriment of chronic medical illness. It also appears that good diabetes quality of care is contingent upon good psychiatric care (psychiatric stability and frequent follow-up), which may lessen the burden of competing mental health issues.

No. 48

Ipratropium as a Rare Cause of Visual Hallucinations: A Case Report

Poster Presenter: Fatima Iqbal, M.D.
Co-Authors: Ali Raza, Zohaib Majid, Asghar Hossain, M.D.

SUMMARY:

Introduction: Hallucinations are intense and substantial sensory perceptions that occur without external stimuli. Hallucinations also differ from delusional perceptions, in which a correctly sensed and interpreted stimulus i.e., a real perception is given some additional/absurd significance. Hallucinations can occur in any sensory modalities i.e., visual, auditory, olfactory, gustatory etc. They are associated with mental illness but also can be related to organic disease and drug or toxic exposure. A visual hallucination is "the perception of an external visual stimulus where none exists". Here we report a case of a 60-year-old male who experienced visual hallucinations while on ipratropium inhaler. Case Description: Patient was a 60-year-old African American male with chronic alcohol use disorder and COPD, who was admitted for rehabilitation from alcohol. While inpatient he suddenly developed visual hallucinations after 15 days. At first it was thought that patient was delirious however all basic lab work such as Complete Blood Count, Complete Metabolic Profile, Ammonia levels and Urinalysis came out to be normal. He was vitally stable. Patient was on standing dose of Ipratropium bromide for his worsening COPD for couple of days that led to development of his visual hallucinations. The visual hallucinations later abated when he was changed to PRN dose of the medication confirming our finding that it was ipratropium induced and relatively rare. Discussion: Ipratropium bromide is a bronchodilator generally used to control and prevent symptoms of asthma and COPD. Ipratropium bromide is an anti-cholinergic agent that blocks the neurotransmitter acetylcholine in the central and the peripheral nervous system. When inhaled, ipratropium travels directly to airways, and very little is absorbed into the body. It has a half-life of 2 hours after inhalation or intravenous administration. Ipratropium bromide is considered well tolerable, with no severe adverse effects or drug interactions. The usual side effects are often disregarded as minor or as result of a patient's preexisting condition. However, the anticholinergic side effects can cause physical as well as mental impairment and are divided into two types: peripheral and central. The anticholinergic effect of ipratropium may be pertinent and relatable to the visual hallucinations. The pharmacoepidemiologic studies have demonstrated possible association between drugs and hallucinations. This relationship involves not only some already suspected drugs but also other drugs less known to induce such an adverse reaction. Conclusion: From the above case, we concluded that the anticholinergic activity of Ipratropium bromide can lead to visual hallucinations that is relatively rare but equally significant. The mechanism of action is not completely understood at this moment and future researches are required to establish this rare side effect of Ipratropium Bromide.

No. 49

Late-Onset Schizophrenia in Patient With Dandy Walker Syndrome: Case Report

Poster Presenter: Fatima Iqbal, M.D.
Co-Authors: Mehwish Hina, Asghar Hossain, M.D.

SUMMARY:

Background: Dandy-Walker Syndrome (DWS) is one of the congenital posterior fossa malformation associated with hypoplasia of cerebellar vermis and dilatation of fourth ventricle. Psychiatric symptoms range from psychosis to cognitive impairment in such cases. In many instances; ataxia, muscular weakness and nystagmus also contribute to clinical symptomatology of the cases. In DWS, mostly there is an early onset of schizophrenia manifesting in late adolescent age. Several cases have been reported where DWS presents as new onset of psychosis especially in adolescent patient. We report a case of psychosis in adults with DWS Objective: The objective of this case is to highlight the late onset of psychosis in DWS and to review the variability in symptomatology. This also enables us to study the long-term prognostic outcome of schizophrenia in co-existent congenital brain syndromes. Case Discussion: 42 y/o M with history of multiple psychiatric hospitalizations admitted to our psychiatric facility with worsening psychosis,

disorganized behavior and depressive symptoms. His first episode of psychosis as reported was at age of 35. During these 7 years he was managed with psychotropic medications while no neuroimaging done. During inpatient stay at our facility, his clinical picture of psychosis complicated with ataxia, which prompted MRI brain – revealing DWS. He responded well with antipsychotics and antidepressants; however, his subtle ataxia persisted and was recommended by the neurologist close observation with serial MRI's. Discussion: Schizophrenia is one the challenging psychiatric illness to manage and has been one of the leading psychiatric diseases claiming for disability in United States. Literature has shown the variability in response to antipsychotics in such congenital diseases, which attributes to pressure effect on brain and potential disruption in brain architecture. Symptomatology may range from subtle ataxia to florid psychosis and significant deficits in cognition. The prognosis of schizophrenia generally depends on the extent of the congenital maloformation and adequacy of social support available in such cases. Our care emphasizes the need to identify any congenital brain malformation in context of schizophrenia in early phase of illness and their prompt and aggressive management to affect the prognostic outcome. Conclusion: The primary emphasis of this case is to highlight the association of schizophrenia with Dandy-Walker Syndrome. Early detection of this inter-relation may affect the outcome of schizophrenia and will help physicians to adapt multidisciplinary approach for effective case management. Significant cognitive deficits, ataxia and muscular weakness may also constitute part of clinical picture and vigilant physical exam is recommended. This observation warrant further studies and follow up in terms of management.

Major Depressive Disorder in a Chronically Ill Patient Unable to Speak: A Case Study on Supportive Psychotherapy

Poster Presenter: Brigitte DeLashmette
Co-Authors: Ramaswamy Viswanathan, M.D., D.Sc., Paulo Marcelo Gondim Sales, M.D.

SUMMARY:
Introduction: Chronically ill patients often develop comorbid conditions that are addressed by a multi-disciplinary team. About one third of them fit criteria for adjustment disorder or another depressive disorder (1). While significant attention is given by the team to the management of general medical problems, the existential needs of this population is not usually prioritized, especially when the patients are difficult to engage or have special communication needs. This case report aims to discuss how to teach medical students basic supportive psychotherapy techniques applicable to patients with special communication needs under severe stress and depressive symptoms. Results: A 54-year-old woman with no prior psychiatric history and a past medical history of hypertension, systemic lupus erythematosus with lupus nephritis, cerebrovascular accident, and NeuroMyelitis Optica (NMO) was admitted for shortness of breath in the context of a flare of NMO complicated by transverse myelitis and new-onset paraplegia. Her hospital course was further complicated by Klebsiella bacteremia, Clostridium difficile colitis, deep venous thrombosis, stage IV sacral decubitus ulcer, and acute respiratory failure that required chronic support with a ventilator through a tracheostomy. She was initially seen by Psychiatry for depressed mood and refusal to undergo frequent painful phlebotomies to monitor her arterial blood gases. After being diagnosed with adjustment disorder with depressed mood, she was started on sertraline 50mg daily due to the severity and chronicity of her depressive symptoms. After two months of her trial on Sertraline, she still endorsed depressive symptoms, but started to develop occasional suicidal ideation with the plan of removing the tracheostomy tube in reaction to acute pain or when feeling isolated. These symptoms ameliorated after she remained for a few days on constant observation, but over the subsequent weeks, she developed conditional suicidal ideations (e.g., if her brother would not be present). She benefited by provision of supportive psychotherapy by the medical students, supervised by a psychiatry resident and attending physician. Discussion: This case illustrates a unique opportunity for medical students to be called upon to help with this patient's need for consistent interaction and support. Supportive psychotherapy interventions are effective to address patients in acute suicidality (2), especially for those struggling

with depressive disorders (3). At the same time, these students gained experience with supportive psychotherapy that applies to other clinically relevant situations. In summary, this case humanized the learning experience of the basic supportive psychotherapy interventions to patients with special communication needs and allowed students to be curious and learn how to provide a biopsychosocial model of care.

Addiction Medicine Education on a Scale From 1 to 5: Review of Teaching Methods and Assessment of Addiction Medicine in Undergraduate Medical School

Poster Presenter: Catherine Boylan
Co-Author: Rashi Aggarwal, M.D.

SUMMARY:
Background: With the ACA expanding substance abuse health care coverage to over 62 million Americans the need for addiction medicine services is growing. Though medical schools are integrating addiction medicine into their curriculum, it is not well known how medical students are receiving education on addiction and whether that education is effective. Objective: Explore teaching methods and learning assessment of addiction education in medical schools. Methods: A literature review was performed by searching PubMed using keywords "addiction" "education" "curriculum" and "medical students" for articles published in the last 10 years. References from articles were also reviewed. Results: Sixteen articles met the inclusion criteria of addiction medicine and undergraduate medical education. They include a mix of educational case studies, qualitative analyses, prospective studies, randomized controlled trials involving one to a few schools, and cross-sectional studies surveying 5 or more medical schools. The literature examined ways which addiction medicine is taught to students, students' reactions to the teaching methods and to addicted patients, when addiction medicine is being taught in the curriculum, and efficacy of the education. The most common modes of teaching cited were didactics, novel elective rotations, and internet-based learning modules. The elective rotations varied from 5 half-days in one week to 7 full weeks. Didactics and internet-based learning were built into the curriculum during the psychiatry rotation, family or internal medicine rotations, or longitudinally across courses and rotations throughout medical school. Efficacy of the addiction medicine curriculum was assessed in 11 articles. Five studies used a qualitative Likert type scale where students scored their own confidence in their training. Three studies analyzed themes in students' reflection essays for their reactions to the learning method as well as their feelings on treating patients with addiction. Only 3 studies used pre- and post-learning examinations and 2 studies used OSCEs to quantitatively evaluate students' acquisition of knowledge. Hours spent teaching addiction medicine were not consistently reported, and ranged from 1 hour to 6 months part time. One study reported aspects of addiction being taught in an average of 258 teaching sessions over the course of undergraduate medical education. Conclusion: As teaching addiction medicine becomes a growing concern, medical schools build the subject into their curriculum using both well-established and modern methods. Little research quantifies students' acquisition of knowledge on how to treat patients with addiction. Standardized assessment of efficacy of the addiction education in medical schools is needed.

Undiagnosed Autism Spectrum Disorder in Adulthood

Poster Presenter: Chineze Worthington

SUMMARY:
Introduction Autism Spectrum conditions are just as prevalent as schizophrenia, 1% across all ages. Traditionally, a diagnosis of Autism had to be made in childhood, contemporary diagnosis no longer has that requirement. The broadening of the diagnostic criteria has made diagnosis in adulthood an important clinical issue. In the 1940s, Infantile Autism was well delineated in children and was thought of as a developmental disorder. The disorder was thought to have onset in childhood and was characterized by social aloofness and obsessive insistence on sameness or routine. Autism presentation in adulthood was not well studied until the 1980s, with the increasing awareness of the heterogeneity of the disorder. The heterogeneity as

well as the work of Asperger in Vienna lead to the concept of spectrum of disorder characterized by developmental difficulties. The diagnosis of Asperger syndrome in DSM IV became applicable to adolescents and adults not well characterized by Infantile Autism, which required delay in language or cognitive abilities. Autism studies have shown that as many as ? of affect Autistic individuals either make it to adulthood without being diagnosed. In addition, gender may play a role in the delay of diagnosis or even miss-diagnosis. We present a case of a 30 year old female with past psychiatric diagnosis of Bipolar d/o, OCD, ADHD and Anxiety disorder, who self-referred due anxiety triggered by disruption of routine at work. Case Patient is a 30 year, single, mixed Ecuadorian and Italian descent, domiciled in a shared apartment with a friend, recently employed as program manager at a non-profit organization that offers free classes, past medical history of mild obstructive sleep apnea, past psychiatric diagnosis of ADHD, Bipolar disorder and OCD, self-referred to outpatient psychiatry clinic with anxiety that's interfering with her job, no history of substance abuse, no family history of DSM diagnosis but notes maternal mother and aunt had fixed way of performing tasks, and reported father had anger managements issues with tendency towards violence. She endorsed chief complaint inability to focus at work. She describes her thoughts as "it feels like there are 15 TVs on different channels and a conveyer belt spinning around my head". In addition she reports getting anxious and agitated at work when her way of performing a task was interrupted or when asked to do it differently. She stated "being around people drains me" and often avoids social activities. Her brain CT scan showed mild bifrontal cortical and superior vermian atrophy. Lab work showed slight elevation in alkaline phosphatase, CBC shows borderline normal hemoglobin level with high variation in size. Her urine toxicology was negative. EEG done recently at outside facility was normal. Neuropsychological testing done at age 16, brought in by patient, showed poor executive function but 96 percentile in IQ. Two ASD screening tools re

No. 53

Training Psychiatry Residents in Long-Term Psychodynamic Psychotherapy

Poster Presenter: Dusan Kolar, M.D.

SUMMARY:

The goal of this review is to provide the structure and specificities of psychotherapy training in psychodynamic psychotherapy for psychiatry residents at Queen's University, Canada. Some common difficulties encountered in teaching psychodynamic psychotherapy to residents will be also outlined. The Royal College of Physicians and Surgeons of Canada requires a minimum of 32 weeks of the PGY2-PGY5 psychotherapy experience. Most of Canadian universities organize training in supportive psychotherapy, cognitive-behavioral therapy and long-term psychodynamic psychotherapy for psychiatry residents. The summer didactic sessions on case formulation and psychotherapy interviewing skills are required before beginning psychotherapy practice. A workshop on Psychodynamic Psychotherapy is included in psychotherapy curriculum and completion is mandatory for all residents. Second year residents provide individual supportive psychotherapy to patients with the minimum of 20 patient sessions in supportive psychotherapy. They participate in group supervision sessions from for 1.5 hours each week for eight months. Fundamentals and common factors in all psychotherapy modalities will be learned during these group sessions in the context of case supervision. This psychotherapy approach has many elements of supportive psychodynamic psychotherapy and this is the best preparation for a long-term psychodynamic psychotherapy. At the beginning of third year of the residency training residents are assigned their long case supervisor and they begin supervised practice in long-term psychodynamic psychotherapy. A minimum of one year of supervised treatment is required for all residents at Queen's University while some others Canadian universities, such as University of Toronto extended this requirement to two years of supervised practice in psychodynamic psychotherapy. Some residents may perceive psychodynamic psychotherapy as too complicated and they may require in supervision more guidance in psychotherapy technique and understanding psychotherapy process. This is understandable because they did not have personal/didactic analysis prior to starting practice in psychodynamic

psychotherapy. Unlike the psychoanalytic training organized by psychoanalytic institutes, training psychiatry residents in dynamic psychotherapy is less clearly conceptualized in terms of standards and expectations from both residents and supervisors. The profile of psychodynamic psychotherapy supervisors for residents may vary significantly with regards to their training, experience and personal style in supervision. Criteria for assessment of resident performance and their progress in training are not well established. Residency training committees and psychotherapy training committees should work on developing more sophisticated training standards of psychodynamic psychotherapy training for psychiatry residents.

Reported Substance Use Among Young Medical Doctors Applying for Medical Residency Programs in Brazil

Poster Presenter: Eduardo de Castro Humes, M.D.

SUMMARY:

Reported substance use among young medical doctors applying for Medical Residency Programs in Brazil Authors: Eduardo Humes, M.D., Renerio Fraguas, M.D., Ph.D. Abstract: Background: We have previously reported the association between reported psychiatric diagnosis (rPD) and poorer performance during Medical Residency Selection in a Brazilian Sample. In Brazil, medical examination for residency programs involves a written examination to access clinical knowledge, and in general also includes a clinical skills evaluation, as well as an interview with curricular analysis. This examination should be the same to any given specialty at each residency training program. Now, in the sample of our previously reported study, we investigated the relationship between the reported use of substances and the performance in the residency selection process, considering the potential influence of a rPD. Methods: The University of São Paulo Medical School (FMUSP) Ethical Review Board approved this study (Registration number 419/2014). Candidates were invited to join the study as they finished the clinical skills examination. All participants signed an informed consent form. Performance on the residency selection was accessed by the final grade on selection process, which takes in account the written clinical knowledge examination, the clinical skills examination, and the interview. Substance use and psychiatric diagnosis were self-reported. Results: The authors invited all 643 candidates and 515 (80.09%) accepted to participate in the study. Sixty-eight participants (13.44%) reported a psychiatric diagnosis and 126 (24.47%) reported use of psychotropic medications on the 3 months prior to the evaluation. The psychotropics most frequently reported were antidepressants, by 67 candidates (13.01%); methylphenidate by 40 (7.77%); and benzodiazepines by 30 (5.83%) candidates. Other, frequently reported medication use, also used aiming at improving the performance on the examination, were beta-blockers (53; 10.29%) and complementary treatments, such as herbal medicines, homeopathy and vitamins (49; 9.51%). Candidates reporting compared to those not reporting use of psychotropics did show a worse performance (p=0.010). However, the significance of this association did not maintain after controlling for rPD. Similar findings were found among candidates reporting use of benzodiazepines (p=0.044). No association was found for antidepressants (p=0.150) and methylphenidate (p=0.541), as well as for beta-blockers (p=0.535) and complementary treatments (p=0.253). Methylphenidate use was not associated to improvement of performance among candidates reporting (p=0.849) or not reporting (p=0.595) psychiatric diagnosis. Conclusion: In our sample, reported use of psychotropics was not associated with differences in performance, including the use of methylphenidate. These findings were present both for those reporting or not psychiatric diagnosis.

No. 55

Family Therapy on the Child Psychiatry Inpatient Unit

Poster Presenter: Elyse Huey, M.D.
Co-Authors: Mariam Rahmani, M.D., Kohl Mitchell Mayberry, D.O.

SUMMARY:

Inpatient psychiatric units can be effective agents for family change. Arguably, the most integral part of treatment during the child's hospitalization is a program of formal family therapy. In numerous training programs, as in our child unit at the University of Florida Health Shands Psychiatric

Hospital Unit, family therapy is led by one case manager and Counseling Students. During certain times of the year, such as semester breaks for counseling students and/or vacation/leave time taken by the case manager, family meetings for some patients were unable to be provided. The goal of this project is to train and integrate our Child Psychiatry Fellows at the University of Florida to lead family meetings while on their inpatient rotation. Some barriers to this goal have been that the Fellow was assigned to the inpatient unit for half-days for some days and they were not provided a formal curriculum for Family Therapy to be utilized on the child inpatient unit. We have started implementing this project by increasing the Fellow's time on the inpatient unit from 0.6 FTE in 2014 to 0.8 FTE in July 2016. This gives them more time to be physically present on the unit and provide more extensive care to the patients in the hospital. We are measuring the Fellow's level of confidence and fund of knowledge in leading family therapy meetings by conducting a pre-survey before they start their inpatient rotation. Fellows will receive didactic seminars on family therapy (at least 4-5 per year) and receive other resources (books, articles) that will help Fellows provide effective family therapy. The family therapy cases led by the fellow will processed in supervision with the Child Attending. Finally, a post survey will be conducted to again measure the Fellow's level of confidence and fund of knowledge in leading family therapy sessions. This project is currently in progress and we expect that this will help in meeting the child psychiatry Fellows ACGME requirements of providing family psychotherapy and family-centered care, as well as improve patient care on our child psychiatric inpatient unit.

Teach Hope for Treating People With Borderline Personality Disorder? A Curriculum on Borderline Personality Disorder for Psychiatry Interns

Poster Presenter: Erica Robinson

SUMMARY:

Title Teach Hope for treating people with Borderline Personality Disorder? : A Curriculum on Borderline Personality Disorder for Psychiatry Interns Co-authors Erica Robinson, M.D, Sarah K. Fineberg, M.D PhD. Background: Many providers feel overwhelmed and ill prepared in caring for patients with Borderline Personality Disorder (BPD). Provider attitudes toward people with BPD may affect the care they deliver. We hypothesized that a focused educational intervention about BPD would increase provider empathy, comfort, and positive attitudes towards patients with BPD. Method: We designed and implemented a unique curriculum for psychiatry interns to learn about BPD. The curriculum was designed to be accessible: it was delivered by a second-year resident (ER), it acknowledged intern uncertainty and frustrations, and it delivered simple useable content. We aimed to increase knowledge and decrease patient- and provider- stigma about the disorder. Interns attended two one-hour didactic sessions. Session one focused on identifying core diagnostic criteria, disclosing diagnosis, etiology, prognosis, and stigma. Session two focused on current treatments and introduced clinical strategies from the Good Psychiatric Management (GPM) manual. Participants: Sixteen first year residents in the Yale Department of Psychiatry took the sessions during their inpatient rotations. Outcome Measures: We administered5-minute pre- and post-tests on the Qualtrics survey platform with short answers and 6-point likert scales to assess knowledge and attitudes. Pre- and post-test scores were averaged and compared using t-tests. Results: Before training, interns associated equally neutral and negative connotations with BPD patients but no positive. There was a significant shift toward positive words after training (t-test $p = 0.019$). Before training, interns correctly listed 2.59±0.30 core diagnostic criteria. After training, this increased to 3.57±0.30 (t-test $p = 0.035$). Intern comfort diagnosing BPD also increased with training: pre-test mean 2.14 ±0.59 increased to post test mean 4.14 ±0.46 (t-test $p = 0.021$). Comfort treating patients with BPD also significantly increased from before (mean score 2.14 ±0.59 to after training (mean score 4 ± 0.48; t-test $p = 0.033$). Conclusions: We developed a novel intervention to increase knowledge and increase positive attitudes toward BPD among psychiatric interns. We implemented the training in a small pilot sample with promising initial results. Future plans include data collection in a larger sample of interns to assess response to intervention, repeated post-test data collection after 6 months to assess durability of the intervention, and distributing the

curriculum to other psychiatric programs. We are hopeful that interventions like this will not only serve as a method of disseminating knowledge to residents but in turn could also lead to lower levels of provider stress when working with BPD.

No. 57

Cost-Efficiency and Utility of Obtaining Routine Admission Laboratory Testing in Adult Psychiatric Inpatients

Poster Presenter: Thripura S. Thirtala, M.D.

SUMMARY:

Routine laboratory testing for all admitted psychiatric patients is predominantly based on concerns that a potential concurrent medical condition may be contributing to the acute psychiatric presentation. Thyroid disease, hypercalcemia, sub acute combined degeneration, and other conditions are well known to occasionally present similarly to primary mental disorders. Public health mandates can also determine the types of tests done routinely during psychiatric admissions. For instance, routine screening for syphilis in newly admitted psychiatric patients occurred in some regions due to the higher risk for this disorder seen in psychiatrically admitted patient populations. The not uncommon failure of preliminary, emergency department medical evaluation of psychiatric patients to adequately detect underlying and potentially life threatening medical conditions, substance intoxication and withdrawal syndromes, and delirium is the subject of myriad studies. Furthermore, among patients admitted to psychiatric units who subsequently are found to have exacerbated or co-morbid medical conditions, considerably fewer underwent thorough laboratory and radiological testing, suggesting that there is an important role for selected diagnostic studies in the evaluation of patients being psychiatrically admitted. A search of the literature suggested that there are relatively few studies analyzing the value of medical test screening in psychiatric admissions. The main objectives of this study are to: • Understand the prevalence of abnormal findings and cost efficiency of lab tests performed routinely during psychiatric admission. • Compare the prevalence of clinically significant lab abnormalities by diagnosis. • Clarify if these tests alter the treatment modalities of psychiatric inpatients. This retrospective chart review will analyze records from more than 100 randomly selected patients admitted to Memorial Medical Center adult inpatient psychiatric unit over an 24 month period to determine how important the routine laboratory screening is for treatment of psychiatric patients. The study will also analyze how the results of screening lab tests are utilized and if any abnormal tests alter our treatment modalities. Descriptive statistical analysis will be performed using excel software. Revisiting the question of utilization of routine screening is important in this age of cost effective health care. Targeted laboratory tests may produce cost savings while not adversely affecting patient care, however the value of routine screening for all patients must be scrutinized carefully. Given the possibility that spurious results may increase costs and create unnecessary anxiety provoking further evaluation.

No. 58

Diagnosing and Treating Bipolar Disorder in Geriatric Population: A Case Report

Poster Presenter: Thripura S. Thirtala, M.D.

SUMMARY:

Mr. SC, a 75 year old Caucasian male patient with past psychiatric history of Major depressive disorder was admitted to medical floor for confusion and altered mental status. Primary team consulted neurology as they suspected stroke. Psychiatry team was also consulted as his stroke work up was all negative and patient was having abnormal behavior, on assessment patient was hyper talkative, grandiose, not sleeping in the hospital, jumping from topic to topic, and had tangential thought process. He was taking Venlafaxine 75 mg and celexa 40 mg at home, psychiatry team thought he might have late onset bipolar disorder, stopped his antidepressant and started on Zyprexa 5 mg qhs and Depakote 500 mg BID, for which patient responded. He was closely monitored in the hospital and in outpatient clinic. Patient mood was stabilized on zyprex 5 mg qhs and Depakote 500 mg BID, later zyprexa was changed to abilify as patient was concerned about weight gain. He is now on maintenance dose of Depakote, and Abilify 10 mg qday. His primary care physician noticed changes in his mental status and behavior and coordinated his

care with psychiatry team. As diagnosing mania in elderly population is uncommon and elderly patients with bipolar disorder are increasing, in this poster we will discuss diagnosing and treating bipolar disorder in elderly population.

No. 59

Case Report: Clinical Challenges in the Diagnoses and Management of Delirious Mania in a U.S. Veteran With a Mental Health History of Bipolar Disorder

Poster Presenter: Muhammad Ali Zaidi, M.D.
Co-Author: Aquanette T. Brown, M.D.

SUMMARY:

A 46 year old Caucasian male veteran with a mental health history of Bipolar Disorder was admitted to the inpatient psychiatric unit following an episode of mania. He was re-started on his outpatient medication regimen for mood stabilization with Quetiapine, Lamotrigine, and Clonazepam. He improved initially, however, on hospital Day 3, the veteran was noted to have acute worsening of manic and psychotic symptoms including, decreased need for sleep, excess energy and responding to internal stimuli. Additionally, he developed symptoms which were atypical for mania, including unprovoked agitation, depersonalization, difficulty sustaining attention, and visual hallucinations. These mental status changes were associated with, excessive motor movement, walking with bizarre postures, squatting, laying taut on the ground, and standing still for several minutes in uncomfortable positions. At this time, Seroquel was switched with Olanzapine for management of mania and psychosis. On physical exam, his vital signs were notable for tachycardia and fever, his extremities were noted to have a normal range of motion; he also experienced loss of bowel continence. The treatment team initiated a medical work up for delirium which revealed no infectious, neurological, or metabolic cause. Of note, there was concern for benzodiazepine withdrawal; however, adequate management did not relieve the symptoms. The veteran was transferred to medicine and neurology was consulted to assist with medical workup. His neuroleptic and benzodiazepine medications were discontinued at that time, except for Lamotrigine. The veteran was then transferred back to psychiatry after medical stabilization, Lamotrigine was discontinued at that time. He was started on Haloperidol, Benztropine and restarted on Clonazepam. At this time, veteran experienced improvement on his mental status exam, with resolution of mania, psychosis, and delirium. However, after two days of treatment, he developed acute rigidity in his extremities. Intramuscular Benztropine and Lorazepam improved his rigidity. Haloperidol was discontinued because of side effects and the veteran was managed with Risperidone and Ativan. He continued to show improvement in his mental status examination and was discharged on a medication regimen of Risperidone, Clonazepam, and Benztropine. The veteran experienced signs and symptoms which were atypical in nature for Bipolar Mania, such as fever, movement disorder, and delirium. This presentation is consistent with a rare medical condition, Delirious Mania for which limited research is available. Delirious mania meets the criteria for mania and delirium without an underlying medical disorder. Delirious mania is a potentially life threatening but under-recognized neuropsychiatric syndrome. Early recognition and aggressive treatment can significantly reduce morbidity and mortality.

Obsessive Compulsive Symptoms May Herald the Onset of Psychosis: A Case of Schizo-Obsessive Disorder

Poster Presenter: Muhammad Ali Zaidi, M.D.

SUMMARY:

On initial inpatient presentation to our community hospital patient was a 28 years old, college educated single male with a new onset Obsessive compulsive symptoms (OCS). Based on the neurobiology of the obsessive compulsive disorder he was started on an SSRI and an atypical antipsychotic. Since it was a judicial hospitalization the patient had a prolonged hospital stay. Patient was continued on this regime; with time he developed disorganized behavior such as licking the floor, continuous banging on doors so much so that it lead to bleeding hands, extremely poor boundary appreciation and hyper sexuality with a tendency to stick his fingers in anus and then licking them. Considering it as a symptom of mania his SSRI was discontinued and he was started on Invega Sustena every 4 weekly. The psychotic

symptoms improved initially for few months but relapsed after a lucid interval of 5 months. The OCS remained as a persistent feature. While initially the patient presented with symptoms in line of OCD. The later development of psychotic symptoms prompted us to consider the obsessive symptoms as a potential prodromal for schizophrenia like illness. Co-occurrence of obsessive compulsive symptoms and psychotic illness was first recognized over a century ago. There is a growing evidence that patients with co-morbid obsessive-compulsive disorder and schizophrenia may represent a special category of the schizophrenia population.

No. 61

Bipolar Disorder in the Setting of Arachnoid Cyst

Poster Presenter: Kamal Patel, M.D.

SUMMARY:

Introduction; Arachnoid cysts are benign space occupying lesions containing cerebrospinal fluid which are usually diagnosed incidentally on neuroimaging due to most cases being asymptomatic. However several case reports have shown coexistence of psychiatric illness and arachnoid cyst, however this clinical presentation varies depending on the size and location of the arachnoid cyst. We present a case of a 51 year old male with bipolar disorder and new onset psychosis. Case Presentation; Patient is 51 year old, single, Caucasian male with past medical history of coronary artery disease, traumatic brain injury, pseudo-seizure, and arachnoid cyst on right middle cranial fossa displacing right temporal lobe tip seen on outpatient setting after being referred by his primary care physician to evaluate for his "depression." Patient had reported having depression since his childhood year secondary to his abuse both physically and sexually from ages five to fifteen. However he also endorsed having mood instability during his teenage years. Patient had reported having several days of elated mood and then days where he felt depressed and down. He denied having periods of time where his mood was relatively stable. He reported having changes in his mood every three to four weeks. During his days when his mood is elated, he endorsed having racing thoughts, irritability, increase activity, energy, irritability, hypersexual with multiple partners, and sleeping 1-2 hours each day. During his initial visit patient was in hypomanic state and then in depressed phase during four week follow up appointment. He also endorsed having paranoia during his follow up visit which he had denied previously. Patient had endorsed increase in intensity of his symptoms over the past couple years and especially over the past six month prior to his initial psychiatric visit. In conclusion, although we cannot certainly conclude the arachnoid cyst as initial cause of patient bipolar symptoms, we do believe it may have contributed with worsening of symptoms.

No. 62

Who Done It? A Stevens-Johnson Syndrome Case Report

Poster Presenter: Lindsay K. Works, D.O.

SUMMARY:

Background: Stevens-Johnson Syndrome (SJS) is a rare, but serious, acute inflammatory skin disease involving necrosis and detachment of the epidermis which is associated with several medications (sulfas, NSAIDs, anticonvulsants) and infections (herpes, Mycoplasma pnuemoniae, EBV). Due to the reaction having many known causes, it can often be difficult to identify the offending agent. The reaction is termed SJS when less than 10% of the epidermis is involved and toxic epidermal necrolysis if it involves greater than 30%. In the practice of psychiatry, the reaction is a known side-effect of Lamictal (Lamotrigine) and there are strict titration guidelines recommended in attempt to decrease the risk of the reaction. Early detection and immediate discontinuation are key to mitigate the severity of reaction. There is typically a prodrome consisting of fever, fatigue, and sore throat 1 to 3 days before eruption of rash, which is often the first indication of reaction and should not be ignored. Psychiatrists are often tested on SJS and are expected to be able to identify the signs and symptoms, but early identification often falls to PCM or ED. Case: 38 year old Indian male with no significant past medical history and previous diagnosis of bipolar disorder presented with complaint of progressive difficulty breathing and painful rash with 5 days of cold/flu-like symptoms despite initiation of antibiotics. The patient had been started on Lamictal nearly five

weeks prior and had slowly been increasing his dose. Cold symptoms were reported and the patient was started on Augmentin by his PCM. The symptoms worsened so the provider switched to Azithromycin. His symptoms continued to progress and culminated in difficulty breathing and painful rash which included genital and oral mucosal. Prominent oral mucositis was noted as well as conjunctivitis and vesicular rash with scattered peticia on groin, chest, abdomen, and legs. After presenting to the emergency room, the patient required emergent intubation due to acute hypoxemic respiratory failure. The patient was stabilized and successfully extubated the next day, but required another two weeks of hospitalization due to severity of his mucosal lesions and requiring IV hydration. Discussion: The patient developed SJS after taking Lamictal, Augmentin, and Azithromycin. Lamictal and Azithromycin were initially both considered culprits. To confirm most likely offending agent, ALDEN algorithm was applied, with the likely triggering agent being identified as Lamictal. The patient had been on Lamictal for about 4.5 weeks. The provider had slowly increased the dose, but at slightly increased rate than recommended. SJS prodrome was missed despite the patient presenting to the ED or PCM three separate times. The severity of the patient's symptoms would have been decreased if Lamictal had been discontinued upon first complaint of rash, as recommended.

No. 63

Managing Longstanding Depression in Bipolar Disorder

Poster Presenter: Maria Plata, M.D.
Co-Authors: Phebe Mary Tucker, M.D., Charles Huston Dukes, M.D., Britta Ostermeyer, M.D.

SUMMARY:

Mr. K is a 53 yo Caucasian male with a psychiatric history of bipolar I disorder, alcohol use disorder, and borderline personality disorder with 48 psychiatric hospitalizations and 20 suicidal attempts. Persistent depression with suicidal ideation in the context of alcohol intoxication led to his 49th hospitalization. Mr. K has been treated with copious combinations of mood stabilizers, antidepressants, and antipsychotics, but he continues to present with ongoing depression. This led to the concern of unsuitable medication management in a patient with long-standing bipolar depression. In this poster, the medication management of chronic depression in bipolar disorder will be discussed with comorbid conditions. Mr. K presented to the ED with plan to slit his wrists in the setting of worsening depression, alcohol intoxication, and a discharge 12 days earlier. He reported initial improvement of depression and medication compliance, but once home he started drinking liquor daily. His medications included fluoxetine 40mg PO QAM, aripiprazole 15mg PO daily, and haloperidol decanoate 50mg IM q28 days. He was diagnosed with bipolar I disorder in 1991and initiated on lithium. His first admission and suicidal attempt was not until 2009 when he presented with depression and mania. Fast-forward 8 years and he's had multiple suicidal attempts with a theme of medication overdose and alcohol. In Dec 2015 he was started on fluoxetine 20mg PO QAM and aripiprazole 5mg PO daily. These medications were titrated to 40mg and 15mg respectively. Haloperidol decanoate 50mg IM q28 days was added in May 2017. On this admission haloperidol decanoate was increased to 75mg. Even so he keeps presenting with deteriorating depression, suicide, and alcohol intoxication. Research on antidepressants has revealed they may be effective in the acute treatment of bipolar I or II with depression, but as opposed to bipolar II, antidepressants in bipolar I are linked to adverse outcomes including an increased risk of mania, rapid cycling, and induction of a chronic irritable dysphoric state. Has fluoxetine induced rapid cycling in Mr. K? Reports suggest that rapid cycling of manic and depressive episodes can be induced by antidepressants and dwindle after their discontinuation. In rapid cycling, a person with bipolar disorder experiences 4 or more episodes of mania, hypomania or depression in 1 year. More commonly, frequent episodes of depression dictate the picture leading to a misdiagnosis of unipolar depression and an episode of hypomania can be mistaken for a period of remarkably good mood. Certainly, substance abuse and an impulsive personality play a role in Mr. K's presentation, but fluoxetine may be contributing to his recurring mood instability and dysphoria. Perhaps tapering the antidepressant with an effective dose of a mood stabilizer approved for bipolar depression is the

solution to this case, as is treatment of comorbid disorders.

No. 64

Menstrual Psychosis in an Adolescent Female: Evaluating and Understanding a Zebra Diagnosis

Poster Presenter: Maura Tappen, M.D.

SUMMARY:

CS is a 16 y/o woman with a history of psychosis who was mental hygiene arrested and admitted to inpatient psychiatry for recent onset of psychosis and erratic behaviors. This was her 3rd admission for psychosis over the past 2 years. Per family, for the past several months prior to admission CS experienced 1-2 week episodes of disorganization with pressured speech, insomnia, and inappropriate laughter. During these periods she failed to take care of basic activities of daily living. Throughout her admission she demonstrated varying levels of these symptoms. The team felt her presentation was most consistent with an underlying bipolar disorder with psychotic features and recommended treatment with a mood stabilizer as well as an antipsychotic medication to help with acute agitation and psychosis as it related to mania. The diagnosis was supported by bipolar disorder with psychotic features in an immediate family member who had responded positively to combination treatment of lithium and clozapine. The patient's family was reluctant to consider this assessment, noting a prominence of symptoms that coincided with the patient's menstrual cycle and urged consideration of menstrual psychosis as diagnosis. Additionally, they refused evidenced based treatments for bipolar disorder, advocating instead for consideration of intervention via hormone medication (clomiphene and thyroid hormone) and nutritional supplementation. The patient's parents' negative association with traditional medication further exacerbated the patient's paranoia and the patient refused all medication. The team pursued a collaborative approach; expert consultation was sought from neurology, gynecology, and UK based academic provider who specialized in menstrual psychosis. Birth control medication was started to minimize potential impact of menses on mood. The team took careful logs of mood and psychotic symptoms, sleep, and menstrual cycles without finding correlation between menses and psychiatric exacerbations. The team weighed the risks and benefits of filing legal action for continued hospitalization and medications over objection, with particular consideration of risks of perpetuating the family's mistrust of the mental health system. An ethics consultation was obtained to help evaluate the balance of beneficence and non-maleficence. Collaborative family work was expanded to include the family member that had responded positively to traditional psychiatric treatments for bipolar disorder. Ultimately, close attention to underlying sources of resistance and barriers to engagement increased cooperative treatment planning resulting in compliance with a mood stabilizer and discharge to home with home based psychiatric interventions and intensive outpatient follow up care. This case highlights an unusual presentation of bipolar disorder that also underscores the unique challenges faced when a family and treatment team have different expectations for diagnosis and management.

Difficulties in Managing Attention-Deficit/Hyperactivity Disorder in Adults With Bipolar I Disorder

Poster Presenter: Mirim Yun

Co-Authors: Yong Chon Park, M.D., Yubin Cho, Seokmin Noh

SUMMARY:

Mr.S., a 20-year-old Korean male with a past psychiatric history of Attention deficit hyperactivity disorder, came to emergency department with recent onset of increased goal directed behavior, pressured speech and violent behavior. He was admitted to the inpatient medicine service 2 years ago. After discharge, he came back to high school. Although he has had medication, he still has had distractibility, irritability. Since he became college student, he had many problems associated with interpersonal relations, maintaining a part time job and organizing things. So he was stressed out and leave school. 2 month ago, he discontinued his medication and has had increased goal directed activity, such as enrollment in computer learning program and English academy. 2 weeks ago, he started to present a pressured talk, hyperactivity,

irritability, insomnia, violent behavior. At admission, medical team made a decision that treat bipolar I disorder first and then titrate ADHD medication carefully. In this poster, we discuss the challenges and importance of differentiating manic symptoms from ADHD symptoms during the treatment and careful titration stimulant for ADHD symptoms .

No. 66

Acute Nicotine Withdrawal Presenting as Manic Symptoms

Poster Presenter: Allison Narta
Co-Author: Caesa Nagpal, M.D.

SUMMARY:

Background: Acute mania is characterized by abnormally elevated mood, decreased need for sleep, inflated self-esteem, distractibility, increased goal directed activity and excessive involvement in pleasurable activities that have high potential for painful consequences. While these symptoms are mostly seen in Bipolar disorder, it can sometimes be seen with use of drugs or several medical conditions. Nicotine has been shown to work on many of the same neurotransmitters as those involved in the proposed pathophysiology behind mania, but it has not been directly linked. We report a case of a 27-year-old Hispanic male with a presentation consistent with symptoms of a manic episode that are suspected to be a result of acute nicotine withdrawal. Method (Case Report): Mr. T, a 27 year old Hispanic male with a past psychiatric history of Bipolar disorder was admitted to an acute psychiatric facility for bizarre behaviors and running around naked in public. Upon examination, the patient was acutely manic with pressured speech, tangential thought process, and poor processing. His mood was labile. He was restless and noted to be pacing and jumping around the unit. He was very intrusive with poor boundaries and was flirtatious with many members of the treatment team. He was started on Quetiapine 200 mg/day. He had a past history of similar episode 8 years ago when he was treated with psychotropic medications for a month and has been off of any medications since that time. Upon further questioning, patient reported being hospitalized about 5 days ago for dizziness, nausea, vomiting, poor appetite, and stomach pain. He had been working in tobacco fields for over 13 hours per day for about 4 months mostly irrigating the fields with chemicals and would frequently not wear protective covering. It is suspected these symptoms were due to acute nicotine intoxication secondary to occupational exposure. He was discharged after 2 days and developed increasingly bizarre behaviors the following day. Over the course of his stay in this hospitalization, Quetiapine was increased to 400 mg/day with the patient displaying resolution of manic symptoms. Discussion: There are many reports of tobacco products favorably assisting bipolar patients with mood regulation. On a grander scale, it is possible that acute nicotine withdrawal may have precipitated this patient's manic episode. It is necessary to be mindful of the possible effects of abrupt nicotine cessation on a patient's mental health and stability as this case demonstrates a clear picture of nicotine intoxication followed by withdrawal and subsequent manic episode. Conclusion: This case illustrated the importance of taking a detailed history and inquiring about tobacco use and nicotine exposure in manic patients.

No. 67

Late-Onset Bipolar Disorder in a Patient With Lacunar Thalamic Stroke

Poster Presenter: Ana Margarida Romao Franco
Co-Authors: Inês Fonseca, Nuno Ribeiro

SUMMARY:

Bipolar disorder (BD) is an affective disorder characterized by fluctuations in mood, energy and activity. Published information regarding BD following stroke is sparse although in recent years there has been an increase in case reports and systematic reviews concerning the subject. A few cases of late onset bipolar disease have been described as a consequence of lacunar ischemic lesions following cerebrovascular disease, with specific brain regions like the basal ganglia and the thalamus being frequently implicated. Recent studies have also implied that intrinsic brain functional connectivity may play a role in bipolar disorder pathophysiology. We present the case of a 55-year-old Caucasian woman with no previous history of psychiatric disease until 2011 when she complained to her Family Doctor about depressive mood, hypersomnia and anhedonia. She was prescribed Paroxetine 20mg with improvement.

These symptoms appeared one year after having a hemorrhagic stroke with a lacunar lesion in the thalamic area and posterior arm of the right internal capsule that resulted in left hemiparesis, with partial response to physical rehabilitation. Four years later she was evaluated at Psychiatric Emergency Service with hypomanic symptoms for which she was medicated accordingly, but she showed noncompliance and stopped all medication. After three years, she was once again evaluated at our Psychiatric Emergency Service with maniac symptoms and admitted to our Acute Psychiatric Unit. She presented with dysphoric mood, pressure of talk, increased energy, flight of ideas, grandiose and mystical delusions and lack of insight. This case suggests a significant role of stroke-associated lacunar thalamic lesions in late-onset bipolar disorders, underlining the importance of searching for brain injury in such patients. The findings of this case are coincident with the most recent evidence regarding brain function connectivity in mood disorders.

No. 68

Culture Clash: Hikikomori's Impact on Assessing Major Depressive Disorder in Japanese-American Adolescents and the Importance of Cultural Competency

Poster Presenter: Samuel Schiavone
Co-Authors: Megan Chochol, M.D., Sean Pustilnik, Ana Maria Jaramillo, M.D., Puja Sawhney

SUMMARY:
Objective: We present a case of major depressive disorder with suicidal ideation in a Japanese adolescent man complicated by cultural stigma toward mental health successfully treated through an innovative approach prioritizing the understanding of Hikikomori. Methods: A review of the literature was preformed using Ovid and PubMed. Results: We present a 16-year-old Japanese man admitted for osteomyelitis and no formal psychiatric history who requested to speak with a psychiatrist. On assessment it was apparent he was suffering from recurrent severe major depressive disorder (MDD) with longstanding thoughts of suicidality. He adamantly refused to involve his parents in his psychiatric care because he felt they would dismiss his concerns, attributing them to a teenage phase, specifically Hikikomori. However, after building rapport, he agreed to involve them. His treatment was complicated by readmission for self-harm after a Japanese internist endorsed his parents' belief that the patient's presentation was a phase of adolescence. An interdisciplinary meeting between US and Japanese providers clarified the importance of psychiatric treatment, and with family support, psychotherapy, and psychopharmacology he has shown significant improvement. Discussion: The DSM-5 recognizes cultural influences on emotional experiences. There are numerous syndromes unique to Japanese culture including Taijin Kyofusho, a fear of one's body or functions offending another1, Hitomishiri, shyness1, and Hikikomori. The concept of Hikikomori is relevant to our patient given its hallmark is social isolation/withdrawal. 2 In a cultural context, widespread use and subsequent normalization of the term help to destigmatize the behavior3 and provide parents a framework within which to understand their children's behavior.2 It is known that minorities are less likely to report psychiatric symptoms and seek help.4 In Japan, mental disorders, specifically mood disorders, are associated with a greater risk of suicide.5 It is important for clinicians to appreciate the extent that cultural beliefs impact willingness to seek help, recognition of serious symptoms, diagnosis, clinical course, and treatment. Our innovative approach built on a foundation of cultural sensitivity strengthened the therapeutic alliance and ultimately helped the patient recover from his severe depression.

No. 69

Identifying the Current Guidelines for Evaluating and Treating Psychosis in a Child With Narcolepsy: A Case Report and Literature Review

Poster Presenter: Marie F. Rodriguez, M.D.

SUMMARY:
The interaction between sleep disorders and psychosis has been moderately studied in adults, but it requires further investigation in the child and adolescent population. This literature review aims to identify the current standards of care for evaluating and treating psychosis and behavioral manifestations in children with narcolepsy, and to discuss treatment options available when variable

barriers to proper treatment are present. Methods: A retrospective chart review was completed, in addition to a PubMed search using the terms “narcolepsy,” “psychosis,” and “children.” Results: A 10 year old Haitian-American male presented to a psychiatric inpatient unit with psychosis, after initially being diagnosed with narcolepsy and started on psychostimulants. He soon began exhibiting psychotic features and was medically hospitalized, but when further diagnostic tests were recommended, his family refused. Hospitalization was on an involuntary basis, as parents also disagreed with psychiatric treatment. His symptoms tended to wax and wane, at times being minimally responsive, at times agitated and responding to internal stimuli. The child was treated with antipsychotics with mild improvement. There were challenges in treating both psychotic and narcolepsy symptoms, thinking about improving one while preventing the exacerbation of the other, all beset with the difficulties of obtaining consent from the family. A review of the literature demonstrated the current standard of care for treatment of narcolepsy in children and adolescents is Modafanil, psychostimulants, and Sodium Oxybate.

No. 70

The Role of Doctor-Patient Relationship on Medication Adherence in Non-Chronic Schizophrenia Patients

Poster Presenter: Jhingoo Chang
Co-Author: Chan-Hyung Kim

SUMMARY:

Background : Although the quality of doctor-patient relationship could influence in medication adherence, only small number of researches support it in schizophrenia. In this study, we investigated the relationship between medication adherence and the quality doctor-patient relationship in non-chronic schizophrenia patients. Methods: We performed a cross-sectional study in one university hospital outpatient clinic. Among 81 schizophrenia patients who agreed with research, we excluded patients who had been treated over 10yrs. 40 patients were remained for analysis. Adherence rate and the quality of doctor-patient relationship were assessed with Medication Adherence Rating Scale (MARS) and Scale To Assess the Therapeutic Relationship (STAR). STAR is a self-rated questionnaire which is consisted with 2 subscales; Non-supportive clinician input and positive collaboration. Demographic and clinical data were also collected. Pearson’s correlation analyses between MARS and STAR were performed. In order to identify the effect of doctor-patient relationship on adherence, a multiple linear regression model was applied with MARS scores as dependent variable. Insight, drug adverse effect were considered potential confounding factors. Results: MARS score was not associated with STAR total score but showed significant correlations with STAR-Non-supportive clinician input score($r=0.51$, $p<0.01$). With the results of regression, medication adherence was significantly predicted from non-supportive clinical input(? = 0.316, $P<0.05$) and medication adverse effects(? = -0.486, P<001). These variables explained 42% of the variance. Conclusions: Clinician’s supportive attitude to patients and effort to reduce the medication adverse effect could improve medication adherence in non-chronic schizophrenia patients.

No. 71

Chronic Urticaria Masquerading as a Selective Serotonin Reuptake Inhibitor Cross-Sensitivity

Poster Presenter: Karolina S. Mlynek, M.D.
Co-Author: Brandon Hamm

SUMMARY:

Dermatological adverse effects from exposure to serotonin re-uptake inhibitors (SSRIs) and gabapentin are uncommon, but adverse reactions have been reported. Chronic urticaria (CU) is a dermatological condition lasting over 6 weeks that is estimated to be experienced by 0.1-3% of persons, and has been found to be associated with neurotic personality traits, very high psychiatric co-morbidity, and impaired quality of life. We report a case of CU after initiation of fluoxetine, with eruptions also following initiation of sertraline and gabapentin. A young adult female of Southeast Asian descent presented with obsessive compulsive personality traits, mild trichotillomania, and a single depressive episode. Past medical history was significant only for mild eczema in the winter months. One month after initiating fluoxetine 10 mg by mouth daily, the patient-noticed early benefit in concentration and anxiety, but developed a pruritic, blotchy,

erythematous rash with 1-2 cm lesions on the arms and face. No angioedema or anaphylaxis was present. Patient denied any changes in dietary habits, hygiene products, and medications. Fluoxetine was discontinued, and rash resolved after two weeks with fexofenadine 180 mg by mouth daily. Two months later, she was initiated on sertraline 25 mg by mouth daily, but after 7 days, the patient awoke with redeveloped rash, though pruritic erythematous maculopapular lesions were much larger than the earlier rash and were restricted to the hands and arms. Zoloft was discontinued and rash again resolved over the course of two weeks on fexofenadine 180 mg by mouth daily. She was then started on gabapentin 100 mg twice daily, with perceived benefit in anxiety, but after 3 weeks, again awoke with pruritic, progressive to rash on the upper arms and hand swelling. The rash resolved with discontinuation and similar treatment to above. Initial consultation with Dermatology and Allergy and Immunology determined inconclusive etiology, with possibilities including atypical presentation of chronic urticaria, serum-sickness reaction, leukoclastic vasculitis. Later dermatological eruption occurred in the absence of medication changes, and biopsy at that time was histologically consistent with urticaria. Chronic urticaria is a dermatological phenomenon that may be experienced in the setting of trialing psychotropic medications for this populations' highly prevalent psychiatric comorbidities. In the setting of rashes following the initiation of dissimilar psychotropic medications, CU should be considered as an alternate etiology to medication allergy, which would entail a different treatment approach.

No. 72

A Case of Olfactory Reference Syndrome Treated With Pimozide and Fluvoxamine

Poster Presenter: Karthik Reddy Cherukupally, M.D., M.P.H.

Co-Authors: Inderpreet Singh Virk, M.D., Tolulope A. Olupona, M.D., Oluwole Jegede, M.D.

SUMMARY:

Introduction: Olfactory Reference Syndrome (ORS) was described over a century ago but very little is published in literature about the syndrome. ORS is described as a false belief that one emits an offensive body odor with prominent delusions of reference and a repetitive set of behaviors aimed at checking or reducing the perceived odor. ORS is often accompanied by shame, embarrassment, significant distress, avoidance behavior and social isolation. Unfortunately, the documented treatment for Olfactory Reference Syndrome is very limited. So far, various treatment modalities have been tried ranging from antidepressants, antipsychotics and cognitive behavioral therapy (CBT) but no consistent clinical improvements has been found and available data is limited on their efficacy. Case Report: We describe a case of a 75 year-old African American woman with a symptom onset of ORS two years ago. The patient was brought in to the emergency room by a family member because of a suicidal attempt. She had reportedly tried to stab herself with a knife. The patient described extreme feelings of guilt, shame, distress, social anxiety to the point of totally isolating herself in her room due to the belief that there is a foul smell emanating from her vagina. Her thought content was also accompanied by extreme delusions of reference. She appeared depressed and hopeless. The patient reported frequent showers and vaginal washes accompanied by multiple visits to gynecologists and other specialists seeking for help. She had also been treated with various medications including Haloperidol, Fluphenazine, Citalopram, Sertraline and Risperidone for an earlier diagnosis of possible late onset schizophrenia/schizoaffective, depressive type, all treatments to no avail. During this admission, however, the patient's diagnosis was revised to Olfactory Reference Syndrome and was successfully treated with Pimozide and Fluvoxamine and she continues to make sustained improvement on outpatient follow up with a complete resolution of her symptoms. Discussion: Currently, ORS has been included in the last Diagnostic and Statistical Manual of Mental Disorders (DSM-V) under the section of other specified obsessive-compulsive and related disorder and not as a major entity. The identification and diagnosis of ORS is complex and critical as there is an overlap between ORS and other disorders as was seen in our patient, she was initially misdiagnosed and treated for schizophrenia without any symptoms improvement.

No. 73

Antipsychotic-Induced Gastrointestinal Dysfunction: A Common Yet Often Overlooked Side Effect

Poster Presenter: Katy Lunny
Lead Author: Monica Cory Federoff, Ph.D.
Co-Author: Alexis A. Seegan, M.D.

SUMMARY:
Constipation is a well-known and often underreported side effect of treatment with antipsychotic medications (1). In fact, patients taking antipsychotic medications are commonly treated with prophylactic bowel regimens, despite the lack of randomized controlled trials demonstrating increased efficacy of one pharmacological intervention for constipation over another (2). Further, while multiple case reports consistently describe the elevated risk of gastrointestinal issues associated with clozapine use, reportedly causing constipation in up to 60% of patients, few studies describe significant associations between other specific antipsychotics and pronounced gastrointestinal dysfunction (3). Here we report a rare case of colonic pseudo-obstruction and paralytic ileus secondary to multiple antipsychotic treatment trials. The patient is a 23-year-old man with a history of schizoaffective disorder, bipolar type who was admitted to the acute inpatient psychiatric unit for suicidal ideation, delusions, and auditory hallucinations in the context of medication non-adherence and cannabis use. Treatment with haloperidol was initiated with minimal improvements in psychotic symptoms, after which haloperidol was cross-titrated with quetiapine, with the patient complaining of constipation after four days. He subsequently developed abdominal distention with watery, non-bloody diarrhea and had several episodes of non-bloody, non-bilious emesis. An abdominal series demonstrated a partial bowel obstruction and significant colonic distension. The patient was urgently transferred to the internal medicine service where supportive treatment resulted in resolution of the pseudo-obstruction and ileus. The patient returned to the psychiatry unit once medically stabilized and his medication regimen was changed to monotherapy with risperidone. Within two days of starting risperidone, the patient again developed abdominal distention with emesis and multiple episodes of non-bloody diarrhea. A CT abdomen was consistent with return of paralytic ileus and colonic pseudo-obstruction, requiring discontinuation of risperidone. The patient was then started on aripiprazole which was selected due to its lower risk of causing ileus after careful review of the current literature . While further studies are required to elucidate potential associations and risk profiles between several antipsychotics and gastrointestinal dysfunction, our findings suggest that prophylactic treatment and recognition of these side effects is important, especially given the potentially fatal consequences of complications. In this poster, we discuss the importance of recognizing the various manifestations of antipsychotic-induced gastrointestinal illness and managing gastrointestinal complications in the context of necessary ongoing antipsychotic treatment.

No. 74

Efficacy and Profiles of Use of Low Doses of Paliperidone

Poster Presenter: Laura Mata Iturralde
Co-Authors: Alba Sedano Capdevila, Raquel Alvarez, Sergio Sanchez Alonso, Santiago Ovejero Garcia

SUMMARY:
Introduction: Antipsychotic treatment significantly reduces the risk of relapse and the secondary tendency to establish a functional disability. Practice guidelines by the American Psychiatric Association recommend the use of the lowest possible effective dose for the maintenance treatment. The antipsychotic paliperidone is available as once-daily extended-release oral paliperidone (ORAL paliperidone),once-monthly LAI paliperidone palmitate (PP1M), and once-every-3-months LAI paliperidone palmitate (PP3M) Objectives: To determinate the patient profile of use and efficacy of low dose of paliperidona (oral paliperidone: 3mg,6mg,9mg,12mg, PP1M: 50mg,75mg, PP3M: 175mg, 263mg) in an outpatient sample. Methods: This is a descriptive analysis of 56 patients with diagnosis of Schizophrenia (Sch), Schizoaffective Disorder (SD), Delusional Disorder (DD) and Bipolar Disorder (BP) recruited for a period of two years in Fundación Jiménez Diaz Hospital, Madrid (Spain). These patients had treatment with low doses of the three presentations of paliperidone. Some variables

were collected: age, sex, type of paliperidone treatment, assistance to psychiatric emergencies and hospitalizations one year before and one year after the initiaton of paliperidone treatment at low doses, years of disease diagnosis, psychiatric comorbidity, pharmacological polytherapy and sexual dysfunction. Results: Our sample comprises 56 patients, 61% were women and 39% men. About diagnosis 9% were BP, 14% of DD, 13% of SD and 64% of Sch. The median age of schizophrenic group was 52 years. Psychiatric comorbidity in 3.5%, substance abuse in 7% and with more than 5 years of diagnosis in 71%. The most used pattern of paliperidone are oral form with N=22 (39.28%) in comparison with PP1M with N= 20 (35.71%) and PP3M with N=14 (25%). Only in the 13% of cases used pharmacological polytherapy. The 96.5% of patients had no sexual dysfunction. The number of hospitalizations during the year prior to the current treatment with paliperidone was N = 15 (0.26%) and after one year of treatment initiation was reduced to N = 3 (0.053%), this difference was significant (p<0,01). The year before the onset of paliperidone, the number of psychiatric emergencies were N = 10 (0.382), and after one year of paliperidone, it was reduced to N = 8 (0.142), although no significant differences were found. Conclusions: Efficacy of low doses of paliperidone was high, with a significant reduction in hospitalizations for 12 months after initiation of treatment. Although it is not a young sample and there is a predominance of patients with more than 5 years of evolution of the disease, the use of low doses of paliperidone (in any of its presentations) should be considered within the treatment strategy in young patients and in the first psychotic episodes, given the efficacy evidenced by the reduction of relapses as well as by the low presence of sexual dysfunction and the low presence of associated po

Recurrence of Psychotic Symptoms When Switching From Long-Acting Risperidone to Long-Acting Paliperidone in a Patient With History of Schizophrenia

Poster Presenter: Lorena Cancino, M.D.
Co-Authors: Eric Michael Ewing, M.D., Raj V. Addepalli, M.D.

SUMMARY:

Risperidone and Paliperidone are atypical antipsychotics that are similar in terms of chemical structure, efficacy and side effect profile. To our knowledge, there have been few reports in the literature that indicate that switching from long acting Risperidone to long acting Paliperidone could cause a recurrence of psychotic symptoms. Patient is a 60 year old Hispanic woman with a past psychiatric history of schizophrenia, no history of substance or alcohol use, and no reported medical history. She had multiple inpatient psychiatric admissions over the previous ten years and a history of noncompliance with medications and outpatient follow up. On her last admission, she was discharged on oral Risperidone and, due to her history of non-compliance, long acting Risperidone at the dose of 25mg intramuscular, was started on her first appointment after discharge. She was compliant with biweekly administration of Long Acting Risperidone for approximately two years. Her primary psychiatrist, honored patient's preference to switch from long acting Risperidone 25mg intramuscular biweekly to monthly Paliperidone Palmitate 78mg intramuscular. She continued outpatient follow up and remained psychiatrically stable in the community for 6 months. However, 3 months after her first dose of Paliperidone Palmitate intramuscular, she was noted to have a brighter affect, and to be more talkative. One week after her last outpatient visit, she was brought in to the Psychiatric Emergency Service due to command type auditory hallucinations to hurt herself and her family. This case raised some concerns regarding the efficacy of switching from depot Risperidone to depot Paliperidone. It is not clear whether her decompensation emerged during the switch of depot antipsychotics, or if it was part of the normal course of the disease. A review of literature indicates differences in mechanism of action and side effect profile between Risperidone and Paliperidone. Switching between medications based on published manufacturer recommendations may require further study to identify the need for individualized switching strategies and dosing to prevent relapse of symptoms in this process.

Rapid and Sustained Improvement in Treatment-

Refractory Depression Through Use of Acute Intravenous Ketamine and Concurrent Transdermal Selegiline

Poster Presenter: Louis A. Doan, D.O.

SUMMARY:

Introduction: Treatment resistant depression remains a difficult clinical challenge for providers and one emerging intervention is intravenous ketamine infusion. Though rapidly effective as an acute treatment, the duration of the ketamine response is brief, and few studies had explored its utility as maintenance treatment. Among oral antidepressants, those in the MAOI (monoamine oxidase inhibitor) class are regarded as some of the most potent but still sparingly used due to adverse effects and dietary limitations. The recently available transdermal MAOI selegiline had lessened these concerns but still not widely used. We examined how a combination of these two powerful treatment modalities, acute ketamine and long term MAOI, can help to achieve and sustain antidepressant effects among severely patients that face imminent or prolonged psychiatric hospitalizations. Methods: Patients with severe, treatment refractory depression who could not undergo ECT (electroconvulsive therapy) were offered ketamine infusion treatment and concurrently initiated on transdermal selegiline patch. Many had failed numerous antidepressants but had not attempted an MAOI trial. Ketamine infusions were performed up to three times within a two-week period. Results: Thus far, five patients have received this combination treatment. Within a few days of finishing the ketamine infusion series, all five patients experienced improvement in depressive symptoms, which was sustained beyond a few months with combination of transdermal selegiline patches. Only one patient relapsed with a depressive episode two years after initial ketamine infusion and stability on selegiline. Discussion: This case series highlights a potentially powerful antidepressant treatment regimen for severely depressed patients unable or unwilling to receive ECT. Ketamine infusions enable patients to improve their quality of life quickly and diminish the prospect of a lengthy hospitalization. In particular, intravenous ketamine was not used as a maintenance treatment but as an acute treatment to offer immediate response until the patient was able to respond to MAOI treatment, specifically transdermal selegiline. The authors have no financial interests that can be seen as a real or perceived conflict of interest. This study has been approved by The Queen's Medical Center of Honolulu, Hawaii Institutional Review Board.

No. 77

Treatment of Raynaud's Phenomenon With the Serotonin and Norepinephrine Reuptake Inhibitor Venlafaxine

Poster Presenter: Madiha Syed, M.D.

Co-Author: David M. Leavitt, M.D.

SUMMARY:

Ms. H., a 38-year-old Caucasian woman suffered from Raynaud's phenomenon since mid-twenties. She experienced vasoconstrictor response of both hands consistently upon exposure to cold environment. Her hands would turn pale and then blue in the cold, and upon return to warm environment, she would experience tingling sensation in her fingers. Raynaud's phenomenon is recurrent vasospasm of the fingers and toes that usually occurs due to cold exposure. Ms. H has been an active runner since adolescence and takes part in marathons regularly but because of her symptoms, she had to discontinue running outside in the winter. She became depressed at 37 years old due to multiple stressors, and was started on venlafaxine (Effexor) to target depression. Immediately after beginning venlafaxine 37.5mg daily, she experienced mild improvement in her Raynaud's symptoms in hands - she recalled her hands not being as cold and pale as they used to be, and progressively over the month, her symptoms completely resolved. She had no previous trials of other agents to target Raynaud's symptoms or depression. She has tolerated an increase to venlafaxine 75mg for depression and her Raynaud's symptoms have remained in remission, allowing her to resume running outdoors throughout the year. One mechanism of Raynaud's phenomenon is considered to be due to the vasoconstrictor property of serotonin. The SNRI venlafaxine blocks uptake of serotonin into platelets and thus decreases the amount of serotonin released during platelet aggregation, which in turn, decreases arterial vasospasm. However, since SNRIs also block

reuptake of norepinephrine, there is a risk of vasoconstriction due to increased noradrenergic activity. Resolution of Ms. H's Raynaud's symptoms may thus be due to the serotonergic effect of venlafaxine. In this poster, we discuss the benefits of venlafaxine in a depressed patient with comorbid Raynaud's phenomenon. A detailed search in the medical literature reveals no previous reported cases of SNRI treatment benefitting Raynaud's Phenomenon.

Managing Erratic Levels of Lithium Following Vertical Sleeve Gastrectomy: A Case Report

Poster Presenter: Mahamaya Bhattacharyya, M.D.
Co-Authors: Sina Shah, M.D., Raj V. Addepalli, M.D.

SUMMARY:

Ms. Z is a 59-year-old woman with a past psychiatric history of Bipolar I disorder admitted to the inpatient service for manic symptoms in the context of non-compliance with medications. Prior to this admission the patient had been following up in the outpatient service of the same hospital for about 20 years and had been psychiatrically stable until recently. The patient is a heavy smoker on nicotine replacement, and blood alcohol levels and urine toxicology screens were consistently negative. Significant stressors included death of her husband and her father two years ago, as well as loss of employment due to an accident one year ago. Patient was started on Lithium carbonate 600 mg BID and Haldol 2 mg BID, and serial Lithium levels were monitored. Interestingly, lithium levels increased from less than 0.2 meq/l to 1.42 meq/l after nine days of administration of Lithium 300 mg in the morning and 600 mg at night time. The blood was drawn before Lithium administration and greater than 10 hours of last dose. The patient's glomerular filtration rate was consistently within normal limits and patient was not on any ACE-inhibitor. The patient did not show any signs or symptoms of Lithium toxicity. Upon further history taking, and corroboration as per records obtained from the operating hospital, it was learnt that the patient had undergone sleeve gastrectomy for weight reduction five years ago. Subsequently Lithium carbonate dose was decreased to 300mg BID and lithium was changed into an extended release formulation and after nine days the level decreased to 0.72. The suspected mechanism which caused lithium toxicity included possibility of increased stomach pH following sleeve gastrectomy which may facilitate the deprotonation of carbonate salt and result in an increased dissolution of lithium ions. Other factors which are poorly understood in patients who have undergone bariatric surgery include the type of formulation used tablet or liquid or extended release formulation, reduction in surface area, changes in transit time and reduction in food ingestion. Other factors which may influence serum lithium levels include gastrointestinal complications such as diarrhea which may cause hemoconcentration and dehydration and increase serum lithium levels. Further studies are required as there is limited literature. Considering that many patients who undergo bariatric surgery have mental illness and are on psychotropic medications, it is important to keep in mind the change in pharmacokinetic behavior of various drugs including lithium which may subsequently cause adverse effects.

No. 79

A Case of Haldol-Induced Syndrome of Inappropriate Antidiuretic Hormone Secretion: Case Report and Literature Review

Poster Presenter: Manan Gupta
Co-Author: Safa Rubaye, M.D.

SUMMARY:

Background: Syndrome of Inappropriate Antidiuretic Hormone Secretion (SIADH) is characterized by increased level of Antidiuretic Hormone (ADH) from the posterior pituitary gland resulting in increasing of water retention and hyponatremia 1. It has been reported that Haldol and other psychotropic drugs are associated with SIADH 1–8. In this article, we are reporting a case of SIADH induced by Haldol and reviewing literature about this rare side effect. Case History: A 34-year old Caucasian Male with history of hypertension and unspecified mood disorder who was transferred from jail and hospitalized for suicidal attempt. Three weeks prior to the admission, the patient was started on Haldol 2 mg at bed-time, while he was in jail, for "mood swings". Abruptly, his sodium level decreased to 116 mmol/L. He was admitted to the hospital for hyponatremia and put

on fluid intake restriction to 1.5 L/day and fluid replacement. Hydrochlorothiazide and Losartan were held as well. The patient was discharged back to jail with a level of 131 mmol/L. Upon discharge, hypertension medicines were restarted. Ten days later, patient was presented to ED with chest pain. Primary team consulted psychiatry for medication recommendation and safety risk assessment. Accidently, sodium level was found to be as low as 114 mmol/L. SIADH was on the deferential diagnosis list due to the presence of hyponatremia, polyuria and polydipsia. Psychiatry recommended stopping Haldol on day 3 of admission. After stopping Haldol, sodium level increased to 136 mmol/L after (day 5). Discussion and Literature Review: In this case, we describe a patient who presented with accidental hyponatremia after three weeks of starting Haldol. Sodium level was corrected by discontinuing the Haldol. Five other cases of Haldol-induced SIADH were reported 2–6. Literature review shows a wide range of dosage and duration of treatment may cause SIADH. A dosage as low as 2mg may cause hyponatremia. However, the duration of treatment varies from few weeks to years. In conclusion, Haldol-induced SIADH is a very rare but serious possible side effect of Haldol and should be on the differential diagnosis list of patients presented with hyponatremia. Detailed work up and treatment is important to diagnose and treat hyponatremia. However, the only effective treatment is discontinuing the causative agent. It is unclear whether dosage and duration of treatment play a role in inducing SIADH as the dosage ranges from 2mg to 80mg. It is also unclear if the presence of predisposing factors is important to develop SIADH in patient on Haldol.

No. 80

Clozapine: The Protean Culprit

Poster Presenter: Samantha Kamp, M.D.

SUMMARY:

M was a 70 year old woman with a documented history of schizophrenia, intellectual disability, seizure disorder, hypothyroidism presenting with painless jaundice in the setting of a biliary tract neoplasm at the confluence of the right and left hepatic ducts. She was on levothyroxine, Donepezil, hydrochlorothiazide, Hydroxyzine, Clozapine and Lovenox among multiple PRN medications. She was admitted to the hospital for a planned ERCP but was found to have an prolonged PTT to 71, also found on previous recent labs. Patient was admitted to the medicine-psychiatry floor to work-up her PTT and assist with medical management. During her lab work-up it was found that in addition to an elevated aPTT, she had an elevated direct and indirect bilirubin, AST, ALT and Alk Phos. Hematology was consulted to assist with the case. It was noted that the patient's 50:50 mixing study did not correct (indicating that she had a circulating inhibitor) and she also had a positive lupus anticoagulant (which can cause a prolonged PTT). Given these alarming findings and the implications for the patient, Oncology was consulted on hospital day 3 to comment on prognosis with and without the procedure given Ms. M's complicated status and concerns that she would appear to require both high-dose steroids (which could cause a psychiatric decompensation) +/- cyclophosphamide and apheresis. Ms. M received pan-scans with results that matched those obtained as an outpatient. Oncology was able to provide that given the likely diagnosis, the patient would likely not have a very long life but the likelihood of the complication of cholangitis and death would rapidly shorten her expected lifespan without receiving an ERCP. Given that the patient did not have capacity to make complicated medical decisions, her Health Care Proxy was reached out to. Given that her proxy was suffering from advanced dementia, it was felt that she would require a new HCP to assist her in decision making. Her remaining relatives, who had not seen her in years, were agreeable to a family meeting and after a great deal of discussion, Ms. M chose a new HCP, who agreed to her need for ERCP despite the risks from treating the elevated PTT. Due to consultation by Hematology-Oncology with outside sources, it was shortly thereafter found that the prolonged PTT and positive lupus anticoagulant were secondary to clozapine and the patient was not at increased bleeding risk. Indeed, she was increased clotting risk. Her ERCP quickly proceeded with no need for the extensive treatments discussed so extensively. Shortly after this she was discharged home on Lovenox and a decreased Clozapine dose.

Gabapentin: Culprit or Cure? A Case Report
Poster Presenter: Selcuk Uremek, D.O.

SUMMARY:
Background: Very little is known about sudden gabapentin cessation, making its management a unique challenge. There are 23 reported cases of gabapentin withdrawal. 6 of these potentially described encephalopathy with agitation. **Case:** A 57-year-old man reportedly taking gabapentin 3600mg daily with history of stroke, hypertension, hyperlipidemia, atrial fibrillation, type 2 diabetes, COPD, asthma, chronic pancreatitis, cocaine abuse, tobacco abuse, frequent falls, and obesity was admitted to the hospital after a falling on his chest, resulting in rib fractures. On arrival, he was found to be retaining urine with acute kidney injury and in diabetic ketoacidosis. He was admitted to hospital for continuous pain management and treatment of kidney injury and ketoacidosis. On day 1 of admission, he had altered mental status and it was thought to be secondary to the opioids he received and metabolic acidosis. On day 2 of admission, he exhibited threatening behavior and psychomotor agitation. Over the next 6 days, the medical team treated metabolic acidosis, hyperkalemia, acute anemia, and acute kidney injury secondary to obstructive nephropathy, and they ruled out alcohol withdrawal delirium, urinary tract infection, hepatic encephalopathy, vitamin B-12 and folate deficiency, and iron abnormalities. ANA was negative. Head CT was negative. CT chest and abdomen positive for rib fractures only. Urine drug screen was not done. During those 6 days he required multiple 4-point physical restraints, and was given benzodiazepines and antipsychotics due to violent and threatening behavior. Psychiatry was consulted and it was noticed that gabapentin was abruptly discontinued on admission. A decision was made to restart gabapentin on day 7. Within 24 hours, his motor agitation resolved and his mental status returned to baseline and he had no memory of being admitted to the hospital. He remained pleasant and cooperative until his hospital discharge on day 10. **Discussion:** Our patient presented with multiple risk factors for encephalopathy: (1)Brain vulnerability with history of stroke (2)Recent physical trauma (3)electrolyte and metabolic disturbance (4)Deliriogenic medications: opioids, benzodiazepines, and medications with anticholinergic effects. Knowing gabapentin increases GABA in the brain, we postulated that abrupt discontinuation of gabapentin could lead to decreased levels of GABA, leading to a rebound excitatory effect, presenting as confusion with psychomotor agitation. Gabapentin withdrawal may have contributed to a complicated multifactorial encephalopathy. **Conclusion:** Although there are no set guidelines to manage abrupt gabapentin cessation, this case demonstrates the need to keep the possibility of withdrawal from medications, including gabapentin, in mind when considering the differential diagnosis of acute delirium.

No. 82
A Case of Human Rabies Encephalitis and a Review of Neuropsychiatric Symptomatology
Poster Presenter: Marie Lyse Turk, M.D.
Co-Author: Lauren Solometo, D.O.

SUMMARY:
Human rabies cases in the United States are rare, with only 1 to 3 cases reported annually. The last time the Virginia Department of Health reported a human rabies case in Virginia was in 2009. A delay in the diagnosis of rabies may lead to fatality as almost all symptomatic patients die from this disease. Obtaining a travel history is often overlooked by healthcare workers (1). We describe the case of a 65 year old female with no past psychiatric history and no past medical history on whom psychiatry was consulted for management of agitation. The patient had no prior medical problems until 3 days prior to admission when she experienced a tingling sensation in her right arm, with pain gradually moving up to her right shoulder. She also developed intermittent shortness of breath and presented to an urgent care clinic and was given meloxicam and hydrocodone for her pain. The patient went to the Emergency Department the following day and had a Chest X-ray, troponins, and D-dimer tested and found to be normal. She was discharged home with Lorazepam for presumed panic attacks. The patient's symptoms worsened as she started experiencing hydrophobia, agitation and confusion. She was brought back to the Emergency Department and was admitted to the MICU for management of ST changes on EKG as well as confusion. A travel history was obtained at that

time and revealed that the patient was bitten by a stray dog while on a recent vacation in India. While in the MICU, the patient became increasingly agitated and required a total of 25 mg of Haloperidol, 1.5 mg of Lorazepam and 2.5 mg of Olanzapine over the course of the night. She was eventually intubated and was diagnosed with rabies via saliva PCR. Patient's respiratory and neurological systems worsened over the course of days and she died after 2 weeks. This case focuses on the importance of obtaining a travel history, the need to recognize the neuropsychiatric symptoms of rabies and the need to seek immediate medical evaluation after an animal bite as fatality from rabies could be easily prevented with prophylactic vaccination. (2)

No. 83

The Emergence of Mania in a Patient With Bipolar Disorder After the Use of Dextromethorphan/Quinidine: A Case Report and Literature Review

Poster Presenter: Marie Lyse Turk, M.D.
Co-Author: John Azer, M.D.

SUMMARY:

Nuedexta, a combination of Dextromethorphan and Quinidine, is an FDA approved medication for the treatment of pseudobulbar affect (1). Until now, there has been no case reports linking the use of Dextromethorphan / Quinidine with the emergence of mania. We describe the case of a 52 year old male patient with a history of Bipolar Disorder Type 1, who was admitted to the inpatient psychiatric unit for management of an acute manic episode. The patient had been enrolled in a research study that was testing the efficacy of Dextromethorphan / Quinidine in treatment-resistant depression and has been taking one capsule of Dextromethorphan / Quinidine per day, with each capsule containing 20 mg of Dextromethorphan Hydrobromide and 10 mg of Quinidine Sulfate. Before his enrollment in the study, the patient did not disclose that he carries a diagnosis of Bipolar Disorder. There was no evidence to suggest abuse of his prescribed Dextromethorphan / Quinidine or of any other substance. The appearance of his manic symptoms seems to be coinciding with the starting of his Dextromethorphan / Quinidine. Although 20 mg of Dextromethorphan Hydrobromide is a dose comparable to cough and cold preparations of the drug, Quinidine dramatically increases the levels of plasma Dextromethorphan due to decreasing its metabolism. The emergence of manic symptoms in our patient, who was stable for several years could have been secondary to Dextromethorphan / Quinidine use, or was simply due to the natural course of his mental illness. It is nevertheless important to highlight the possible risk of switching to mania which has not been previously documented or mentioned in the drug pamphlet. This case also focuses on the importance of retrieving psychiatric records before enrolling patients in a study in order to prevent the worsening of their illness and to obtain more accurate and non-confounding results.

No. 84

A Case Report of Tardive Dyskinesia Caused by Clozapine Withdrawal

Poster Presenter: Marie Lyse Turk, M.D.
Co-Author: Anita Louise Hammer Clayton, M.D.

SUMMARY:

Tardive dyskinesia affects 9% of patients who are treated with an antipsychotic medication (1). Clozapine has a low risk of causing extrapyramidal symptoms. Some studies also showed that Clozapine is effective in improving symptoms of tardive dyskinesia (2). Little is known about the risk of developing tardive dyskinesia as a result of decreasing or discontinuing Clozapine. We describe the case of a 23 year old woman, diagnosed with schizoaffective disorder, bipolar type, who developed tardive dyskinesia in the context of Clozapine non-compliance. The patient has been on Clozapine monotherapy for 3 years and her most recent dose was 150 mg daily. The only other medication that was added to her regimen was Lamotrigine to target her mood lability. She presented to the clinic for follow up with new onset jaw and tongue movements, and had an AIMS score of 13. She reported that she has been skipping some Clozapine doses. On follow up, her AIMS score decreased to 1 after resuming her full Clozapine dose. We will discuss the pathophysiology of tardive dyskinesia and how some antipsychotic medications can cause or alleviate symptoms of this disorder, including Clozapine. We will also expand on the potential relationship between the emergence of

tardive dyskinesia in the setting of Clozapine dose reduction or discontinuation, which was discussed in few case reports (3).

No. 85

Psychiatric Management of Patients With Wilson's Disease: A Case Report

Poster Presenter: Sahil Munjal, M.D.

SUMMARY:

Wilson's disease (WD) is a rare autosomal-recessive, inherited disorder caused by a mutation in the copper-transporting gene ATP7B affecting the liver and nervous system. About 30% of patients with WD may initially present with psychiatric symptoms, and diagnosis can be difficult to establish. The diagnosis is often delayed when psychiatric symptoms preceded neurological or hepatic involvement. These patients commonly undergo psychiatric treatment before they are diagnosed and get treated with specific chelation therapy. The mechanism of psychiatric symptoms in Wilson's disease is not clear. As they can occur at the start of the illness, they are not fully explained by the psychosocial impact of a medical condition. Initially it was thought that basal ganglia abnormalities led to various psychiatric symptoms through dopamine dysregulation. More recent studies have explored the role of copper and other microelements in schizophrenia and bipolar illness. Although the lifetime prevalence of psychiatric symptoms in WD patients is unclear, the estimated range is from 30 to 100% of symptomatic patients. Specific therapies for WD lead to a good life expectancy, adherence to medications and clinical monitoring should be warranted by a multidisciplinary approach, including a hepathologic, neurologic, and psychiatric careful evaluation along with education of those affected and their relatives. These patients do exhibit sensitivity to antipsychotic medications, Close collaboration with the medical team is essential in the long-term management of these patients. Treatment of psychiatric symptoms in WD may require slower titration of psychotropic medications and should accompany therapy for WD directed at the prevention of accumulation and the removal of copper. Even when severe psychosis is present, the aim of care should be full recovery, since patients may maintain remission for years after psychotropic medications have been discontinued. We present a case of a 37 yo male with multiple psychiatric hospitalizations, acute behavioral issues with irritability, poor frustration tolerance, lability, later diagnosed with Wilson's disease. His serum copper and ceruloplasmin levels low, urine copper levels were high. MRI of brain showed mild cerebral volume loss, evaluated by ophthalmology and the patient was positive for Kayser- Fleischer rings. We will present the challenges faced in the management of this patient and will review the literature on the treatment of psychiatric symptoms in patients with WD.

No. 86

Ziprasidone in the Treatment of Stuttering

Poster Presenter: Sahil Munjal, M.D.

SUMMARY:

Stuttering is a disturbance in normal fluency and time patterning of speech that is inappropriate for the person's age. The prevalence of stuttering is approximately 1% of the population, affecting an estimated 3 million individuals in the United States. Various factors like incomplete lateralization of abnormal cerebral dominance, genetic factors and overactive pre-synaptic dopamine systems in regions of the brain that modulate verbalization have been implicated in the etiology of stuttering. The dopamine hypothesis of stuttering explains that abnormally increased cerebral dopamine affects the balanced levels that maintain the basal ganglia circuits, which helps with timing cues in initiating speech. Pharmacologic research has suggested that older generation dopamine antagonist/ typical antipsychotic medications improve stuttering symptoms, but are associated with poorly tolerated adverse effects. Also, there has been evidence of atypical agents including risperidone, olanzapine, asenapine and aripiprazole in the treatment of stuttering. Till date, there is no published report on the use of ziprasidone which has a much favorable metabolic profile. Here, we present a case of stuttering resistant to speech therapy that remitted with ziprasidone. Mr. X is a 42 yr old male with a h/o Bipolar 2 disorder who presented to the outpatient clinic on the regimen of valproic acid, venlafaxine, clonazepam and risperidone for continued medication management. He reported that he had

been prescribed risperidone for many years for his stuttering by his previous psychiatrist to good effect. However, patient had significant side effects including hypertriglyceridemia and breast enlargement. The patient was weaned off the risperidone and Stuttering Severity Instrument (SSI) was administered and the score was compared to the score on this instrument on the ziprasidone. Patient had a total score of 31, which is a "moderate-severe" vs 21 which is a "mild" rating for adults with dysfluencies. Patient exhibited 16% vs 4% stuttering or dysfluencies in a reading task, 21% vs 8% dysfluencies in a descriptive task, 51% vs 13% dysfluencies in a conversation, 16% vs 0% dysfluencies in the counting speech task. Lastly, the prolongation of sounds lasted from 1-8 seconds vs 2 seconds. Overall as per the speech pathologist's evaluation, patient had improved significantly from his initial assessment. Patient's metabolic profile improved as well. This suggests that ziprasidone may be an effective and well-tolerated medication for the treatment of stuttering.

No. 87

Analysis of Simulated Patient Interviews as a Teaching and Resident Assessment Tool

Poster Presenter: Alexander C. L. Lerman, M.D.
Lead Author: Peter Spyrou
Co-Author: Katherine G. Nordgren

SUMMARY:

Rationale: Interviewing is a critical skill for both psychiatric and non-psychiatrist clinicians. Many patients fail to disclose important information, due to shame, fear of the interviewer's response, secondary gain, or a variety of other factors. Our current findings indicate that beginning interviewers tend to have difficulty with such patients. This training builds skills in understanding and engaging non-disclosing subjects, through a collaborative process of group and self-study (Shea 1998) Methods: Learners in our simulation center conduct videotaped interviews with professional actors portraying challenging patients (i.e. paranoid, self-deceptive, psychopathic). Videos are evaluated and rated by a team of trained learner/raters using scales to assess basic interviewing, empathy, and advanced interviewing techniques (identification of discrepancies, confrontation, management of interviewer's anxiety, etc. Every effort is made to reduce anxiety and engage learners in a non-judgmental, constructive and affirmative discussion process. Results are shared privately + included in didactic presentations to groups of learners. Further research data will focus assessment of skill development over training, and correlation between interviewing/formulation skills and other benchmarks of training progress. Interviews are conducted through the year, with feedback and assessment occurring thought the academic calendar. This program is already under way, and has generated > 100 hours of interview material. Evaluation plan: This advanced Simulated Interview program has been highly successful and generated interest and participation among residents. Unlike patient material, SP interviews have no privacy concerns and can be widely used in supervision, didactics and resident assessment. Qualitative assessments have added depth to evaluation and feedback to learners. Rating assessment tools focus on four domains: basic interviewing, empathy, formulation guided interviewing, rapport. The experience of rating interviews, and watching other learners engage the identical clinical scenario is unique to the simulated patient exercise. Both psychiatric residents and medical students have enjoyed participating.

No. 88

"Biggie," a Non-Disclosing Patient: A Clinical Exercise for Psychiatric Residents

Poster Presenter: Alexander C. L. Lerman, M.D.
Lead Author: Katherine G. Nordgren
Co-Author: Peter Spyrou

SUMMARY:

Patient distortion and non-disclosure (DND) is a ubiquitous behavior which frequently distorts patient outcome and triggers conscious and unconscious withdrawal on the part of the clinician. When detected and engaged, DND behavior represents a mental status finding which can offer unique insight into a patient's motivation and psychopathology. Indicators of DND include a distorted narrative (e.g. breaks in timeline, logical inconsistencies), non-verbal affective "tells" (e.g sighs, tears, changes in vocal tone), clinician "counter-transference" emotional response (e.g.

boredom, anxiety, feelings of incompetence, and psychological withdrawal)" Patients may or may not be aware that they are engaging in DND, which can be driven by a range of heterogeneous factors including anxiety, shame, and fear of clinician or institutional response to candor. This presentation represents an aggregation of data derived from videotaped interviews with a simulated patient presenting with relatively obvious factitious symptoms, and underlying problems of depression and chronic developmental trauma Methods: Formal evaluation of the clinician's interview rests on qualitative assessment of empathy, specific information that is or isn't elicited during the interview, and the clinician's capacity to develop a clinical formulation and treatment plan and communicate this to the patient. During the simulated patient (SP) interview, each patient starts from a position of relatively obvious non-disclosure, while simultaneously offering nonverbal cues and openings for more meaningful engagement. More information is provided if, and only if, interviewer follows up. Selection and placement of transactional "gates" put emphasis on non-linear interviewing strategies, including use of a global case formulation, "following affect", and integrating emotional support while identifying and engaging points of non-disclosure in the patient's presenting history. Evaluation plan: 22 psychiatric residents in their 2nd-3rd training years were presented with the same 15-minute Simulated Patient "Biggie". Interviewers were instructed to reach a decision of whether or not to hospitalize the patient by the end of the interview. Interviewers were assessed by non-blinded raters for a) discernment of patient's non-disclosure b) empathy and response to affective cues, c) persistence in patient assessment. Results: All interviewers correctly determined that the patient should be hospitalized. Qualitatively, interviewers appeared to be either frustrated or confused by the patient's falsified symptoms, and to adopt one of two postures, or oscillate between them: "Bobble-heading", i.e. nodding and making verbal affirmations excessively while providing no structure during the interview, in response to which the patient produced irrelevant material; "Templating", i.e. reverting to standardized mental status and DSM-driven interview questions of limited relevance.

No. 89

Severe Persistent Anxiety and Labile Mood: Remember Cannabis Withdrawal Syndrome!

Poster Presenter: Michelle Lynn Bryant, M.D.
Co-Authors: Nicole Abbot, M.B.B.S., Vinod N. Alluri, M.D.

SUMMARY:
After years of debate over the existence of cannabis withdrawal syndrome (CWS), proponents have realized its inclusion in the DSM – 5. It features multiple mood and somatic symptoms that could last up to a month. Psychiatric co-morbidity and co-morbid substance use disorders may complicate management and cause a more severe presentation. We present a case of a patient with CWS with prominent anxiety, and mood lability despite appropriate medication trials resulting in a prolonged and perplexing course. 41-year-old lady with a history of traumatic brain injury, cannabis and tobacco use disorders, schizoaffective disorder, and unspecified anxiety, presented with latency of speech, thought blocking, labile mood, disorganized thought process, heightened anxiety and inability to function. At the time of admission, she was continued on her home medications: lamotrigine, lithium, duloxetine, gabapentin, clonazepam, eszopiclone, and hydroxyzine. She was previously started on a clonazepam taper as an outpatient due to substance use problems, however due to concerns for benzodiazepine withdrawal clonazepam dosage was increased but with limited effect. During her hospital course, she fluctuated between being very irritable, to being more docile. She remained very anxious, paranoid and easily confused which resulted in non-fluent speech, and restlessness. She had neurological symptoms that included confusion, tinnitus, and headache. Brain MRI without contrast showed no significant abnormality. Initially quetiapine was added, which was later cross-tapered with fluphenazine which improved her paranoia and disorganized thinking. Duloxetine was increased from 60mg to 90 mg daily for anxiety. Lithium was initially increased from 600mg to 900mg for mood stabilization but was decreased back to 600mg due disturbances in coordination. Her blood pressure was elevated and was treated effectively with metoprolol. Her symptoms gradually improved

such that at the time of discharge she had regained functionality, her mood was pleasant, and anxiety was controlled. The DSM-5 suggests that up to one third of regular cannabis users experience withdrawal and it lists the following symptoms; irritability, anger, or aggression; nervousness or anxiety, sleep difficulty, decreased appetite or weight loss, restlessness, depressed mood, and somatic symptoms such as headache. Differentials for our patient's presentation included tobacco withdrawal, and benzodiazepine withdrawal from recent taper of clonazepam, however symptoms did not abate with nicotine replacement therapy or with increasing benzodiazepine dose, and persisted for weeks. Literature on treatment is sparse. Gabapentin and cannabinoid analogs have shown benefit (1). Lithium did not show efficacy over placebo (2). Cannabis use disorder and withdrawal syndrome could be more severe and complex in the presence of co-morbid psychiatric illness and substance use. More studies are needed on effective treatment options.

No. 90

A Case Report of Aripiprazole Leading to Pathological Gambling Activity

Poster Presenter: Michelle Tom

SUMMARY:

Aripiprazole is an atypical antipsychotic FDA approved for the treatment of schizophrenia and mood disorders and can be used as an off label to treat other psychiatric conditions, such as tourette syndrome and stuttering. It acts as a partial agonist at dopamine receptors with increased affinity for receptors D2 and D3. Some of the known side effects of aripiprazole include orthostatic hypotension, akathisia, anxiety, and weight gain. Recently, there have been increased reports of unexpected behavioral changes, such as decreased impulse control, that occurred with aripiprazole. Cases of gambling disorder have been reported as an adverse effect following treatment of psychosis with aripiprazole. Here, we present a case report of a patient with stuttering who developed pathologic gambling activity after treatment with aripiprazole. Gambling impulses subsequently resolved when aripiprazole was switched to Cariprazine, a D2 and D3 receptor partial agonist with high selectivity towards the D3 receptor.

No. 91

Delirium Prediction Utilizing Text Mining and Machine Learning Algorithms

Poster Presenter: Gen Shinozaki, M.D.
Co-Authors: Nick Bormann, Sivakrishna Kuragayala, Lindsey Gaul, Mason Klisares, Julian Robles, Jonathan Heinzman, Gabrielle Duncan, Sydney Jellison, Nicholas Coon, Theodosis Chronis, Kasra Zarei, Kumi Yuki, Sayeh Sabbagh, John Cromwell

SUMMARY:

Background: Delirium is a fluctuating level of consciousness that stems from underlying physiologic/medical disturbances. Current screening methods are designed to identify delirium once it is present. Electronic records in modern healthcare systems allow for the identification of at-risk patients by utilizing automated mathematical modeling. Through this approach, machine learning and predictive analytics can identify patients who are at risk for developing delirium from patients who have not developed delirium based on progress notes and lab data. This study aims to investigate the effectiveness of this approach and introduce the concept of using models for early identification of at-risk patients prior to the clinical onset of delirium. Methods: We examined records from two cohorts of patients: 1) general medicine patients, and 2) orthopedic hip fracture repair patients admitted to the University of Iowa Hospitals and Clinics. Delirium status was confirmed through chart review. Daily progress notes, lab data and patient demographics were obtained from the electronic medical record. Text mining, using latent semantic analysis , was employed to extract concepts from unstructured progress notes. Two independent concepts served as continuous features in subsequent models of delirium risk. Words highly associated with delirium cases (i.e. delirium, encephalopathy, EEG, etc…) were marked as stop words and removed from the analysis. Discretely encoded variables of albumin, BUN, WBC, AST, history of dementia, age, and BMI were included based on a previous machine learning model examining ~13,000 subjects, which demonstrated their importance as predictors. Statistica (v 12.3) and R (v 3.4.1) were used for

analysis. Results: 243 patients (93 positive for delirium and 150 negative controls) participated. The discrete variables and extracted concepts on these subjects were used in subsequent machine learning models. A neural network model provided the best results. 83 of 93 delirious patients (sensitivity 89.2%) and 133 of 150 controls (specificity 88.7%) were correctly predicted (accuracy 88.9%). When compared with discrete data alone, these results emphasize the value of the previously underutilized free text contained within the electronic medical record. Conclusion: Our data illustrate the strength of using predictive algorithms created from pre-existing data from patient charts. Future investigations will focus on patients who enter the hospital non-delirious and subsequently develop delirium. Our validated model will be executed repeatedly throughout their stay to identify potential lag time from positive algorithm-based screening to clinical recognition of delirium.

No. 92

Diagnostic Approach to an Active Duty Servicemember With an Evolving Presentation of Major Depressive Disorder and Psychosis

Poster Presenter: Savannah Lee Woodward, M.D.
Co-Authors: Robert Myslin, M.D., Laura Francesca Marrone, M.D.

SUMMARY:

One of the unique features of psychiatry is the complexity of the factors that contribute to the presentations of our patients. There is little in the literature, however, that discusses a multifactorial approach when assessing and evaluating a diagnostically unclear case. This poster will examine the case of a 20 year old active duty service member who presented with bizarre and atypical suicidal and self-harm thoughts with marked thought disturbance in the context of starting his School of Infantry training at the beginning of his enlistment. Throughout his month-long hospitalization, his presentation ranged from that of Persistent Depressive Disorder to Schizophreniform to Unspecified Anxiety, to the final diagnosis of Major Depressive Disorder with Psychotic features, and appeared to evolve with the initiation of each new pharmacologic intervention. We will discuss the extensive medical and psychological work up completed in this patient, with particular attention to his response to multiple neuroleptics and antidepressants, the results of extensive psychological testing, and ultimately a possible concern for a variant of Wilson's Disease. Additional considerations will include a complex stress diathesis construct examining how multiple social factors including a childhood characterized by periods of neglect and social isolation, maternal history of Bipolar Disorder and Alcohol Use Disorder, and Native American Reservation upbringing, may have contributed to this patient's initial decompensation in the setting of a highly stressful military training environment.

No. 93

The Delayed Diagnosis of Multiple Sclerosis in a Patient With Comorbid Posttraumatic Stress Disorder, Major Depressive Disorder, and Migraines

Poster Presenter: Heather Anne Jones, D.O.
Co-Author: Anil Sighal, M.D.

SUMMARY:

Mr. P is a 35 year old Caucasian male with a past psychiatric history significant for Post Traumatic Stress Disorder and Major Depressive Disorder with a history of comorbid chronic migraines who presented for a Neurology consult following a sixteen month delay in referral. On physical exam at this time the patient was found to have difficulty maintaining lateral gaze, hypersensitivity to pain sensation on the first rib on the right, a positive Rhomberg's test and an inability to do tandem walking or to stand on one leg for any period of time. A thorough review of systems revealed significant changes in vision, headaches, loss of balance, gait disturbance and dizziness for the past year. The patient was seen multiple times in a Veterans hospital system by a Psychiatrist and a Primary care physician during this sixteen month time period. The patient presented to his primary care physician on multiple occasions requesting a referral to Neurology for his persistent headaches. He was denied this request during multiple visits and his complaints were dismissed as psychiatric in nature. The Psychiatry notes indicate that he attempted to address these issues with this physician and he was dismissed and diagnosed with an axis two disorder due to his complaints and

worsening depression symptoms. No Neurological examination was ever performed at any of the eighteen Psychiatric and Primary Care visits. In this poster we discuss the difficulty in diagnosing multiple sclerosis in patients with comorbid psychiatric illness and the importance of a thorough Neurological examination in this patient population.

No. 94

Subjective Memory Complaints and Symptoms of Nightmare in the Elderly With Chronic PTSD

Poster Presenter: Moon Yong Chung
Co-Author: Sukhoon Kang

SUMMARY:

Objectives: The association between sleep disturbances wit nightmare and cognitive decline in the chronic PTSD has been putative and controversial in the elderly. We evaluated the relation between sleep problem with nightmare and cognitive function in the chronic PTSD patients. Method: 80 subjects with chronic post-traumatic stress disorder (PTSD) and without depression or neurologic disorders (mean age 67.2±6.1) were analyzed in this study. All the participants completed the Korean version of the consortium to establish a registry for Alzheimer's disease neuropsychological battery (CERAD-KN) as an objective cognitive measure and subjective memory complaints questionnaire (SMCQ). Based on the clinical interview and item of B-2 in the clinician-administered PTSD scale for diagnostic and statistical manual of mental disorders 4th (CAPS-IV), 3 points and more was categorized "nightmare (+)" and 1~2 points was defined "nightmare (-)". Results: All subjects were men, 42 with normal to mild nightmare and 38 subjects with moderate and severe symptoms of nightmare. PTSD subjects with frequent nightmare reported more depressive symptoms and more use of sleep medication, and showed higher SMCQ scores than PTSD with mild nightmare, but there was no difference in any assessments of CERAD-KN. In the regression analysis, depressive symptoms and sleep disturbance with nightmare were associated with subjective memory complaints (?=0.288, p<0.001; ?=0.189, p=0.005). Conclusion: In the elderly patients with chronic PTSD without depression, sleep disturbance caused by frequent nightmare was associated with subjective memory complaints, but not with objective cognitive measures. As subjective memory complaints might develop into cognitive disorders, clinicians should be aware of significance for subjective memory impairment at examining prominent symptom of nightmare in the elderly with chronic PTSD.

No. 95

So You Want to Start a Mental Health Film Series!

Poster Presenter: Harry Karlinsky, M.D.

SUMMARY:

The use of dramatic and documentary films as pedagogical tools to explore the stigma, representations and misrepresentations that surround mental illness and addiction is now well known and accepted. Towards this end, an increasing number of student/resident training programs, consumer and arts organizations, health care settings as well as academic institutions are now running ongoing film series and festivals to promote both public and/or professional education of matters related to mental illness and wellness. This abstract aims to share these real-world experiences by presenting a case study: the University of British Columbia's Frames of Mind Mental Health Film series. Initiated in 2002, Frames of Mind consists of monthly evening screenings (at the non-profit Cinematheque theatre in downtown Vancouver) of a commercial feature length dramatic film or documentary directly related to a particular mental health theme, which is then followed by a presentation and Q and A (see http://www.framesofmind.ca for further details). Over 15000 individuals have now attended the film screenings; over 100 community organizations have been involved as community partners and co-sponsors of specific screenings; and speakers have ranged from psychiatrists to individuals with lived experience to film directors. The "nuts and bolts" that underlie the successful operation of a mental health film series will be identified, including the requisite issues of film and speaker selection, marketing and promotion, partnerships, financial sustainability, choice of venue, community engagement, accessibility, safety and evaluation strategies. In anticipation that some Conference attendees may wish to establish similar programs in their own jurisdictions, and for those already doing

so, we also hope this poster generates interest in establishing a supportive community of practice of those involved with mental health film series. The envisioned benefits would include information sharing, the establishment of communal resources (such as inventory of mental-health films) and joint enterprises such as touring collaborations.

No. 96
Zelig's Syndrome: Reel or Real?
Poster Presenter: Harry Karlinsky, M.D.

SUMMARY:
In his film titled Zelig (released in 1983), Woody Allen introduced the world to the story of Leonard Zelig, a man who could seamlessly and involuntarily mirror the identities and, even more remarkably, the physical characteristics of those in his immediate proximity. Zelig could become, among other examples, an Oriental-looking man in a Chinatown restaurant, a corpulent individual in the company of the obese, and even a black trumpet player when drinking at a Chicago speakeasy (the film is anchored in the Jazz age of the late 1920s). Not surprisingly, Zelig's seemingly impossible transformations bring him to the attention of the psychiatric profession. Despite diagnostic and therapeutic missteps, professional boundary violations, and serious relapses along the way, Zelig's psychiatrist - Dr. Eudora Fletcher - eventually cures Zelig's unusual illness with an unorthodox approach involving reverse psychology, hypnotic trances, and unconditional love. Yet curiously, Leonard Zelig's story did not end with the closing credits of Allen's mockumentary. Reports began to emerge in the psychiatric literature of real patients with "Zelig-like" symptoms. Did Woody Allen anticipate a new psychiatric disorder? Could so-called Zelig's syndrome actually exist and, if so, by what underlying psychological and physiological means? This poster summarizes the relevant literature pertaining to "Zelig-like" phenomena, and draws particular attention to the following issues: the construction of identity, echophenomenon, mirror neurons, and the environmental dependency syndrome. Learners will be left with that old conundrum: does life imitate art or is it the other way around?

No. 97
Assessment of Social and Emotional Well-Being in Australian Aboriginal People
Poster Presenter: Aleksandar Janca
Co-Author: Zaza Lyons

SUMMARY:
Background: The assessment of Social and Emotional Wellbeing (SEWB) among Australian Aboriginal people is a complex and challenging task. Adoption of a yarning approach during an interview and demonstration of cultural competency and sensitivity is important. There are limited tools and instruments that can be used to assist in the assessment process. The aim of the project was to develop a culturally appropriate screening tool for the assessment of mental health problems in Australian Aboriginal people. The focus of our screening tool was on the current (i.e. here and now) mental health problems including the Aboriginal concept of SEWB. Consequently, the tool we developed was entitled Aboriginal Here and Now Assessment (HANAA). Methods: The initial phase of HANAA development involved consulting with key informants across Western Australia who work in the field of Aboriginal SEWB. A glossary of terms and concepts relating to SEWB was developed to identify ten key domains. These included physical health, sleep, mood, suicidality, substance use, memory, unusual experiences, functioning, life stressors and resilience. The HANAA is implemented by initiating a semi-structured interview that covers each of the domains. The respondent is encouraged to tell their story in the form of a narrative which is recorded by the interviewer. The aim is to determine if there is a problem or not, in each domain. At the end of the interview a 'recommended action' is determined. The HANAA was evaluated by exploring cultural applicability, feasibility, reliability and validity on a sample of 30 Aboriginal participants from urban and rural settings across Western Australia. Results: The cultural acceptability of the HANAA was rated highly. Reliability was good with agreements between Aboriginal and non-Aboriginal interviewers measured by kappa statistics ranging from 0.5 to 1.0. Overall agreement between interviewers on the narratives ranged from 60% - 96%. There was also good agreement between interviewers and treating

clinicians in identifying the main SEWB problem and recommended course of action. Conclusion: The HANAA is a culturally acceptable, valid screening instrument for the assessment of SEWB among Australian Aboriginal people. It can also be used as teaching and training tool for various types of mental health, general health and other professionals who deal with Aboriginal people in the context of education, legal and prison systems etc. This was an unfunded study.

No. 98

Creating a Self-Sustaining Naloxone HCL Education and Distribution Program for Families and Care Takers of Adolescent Opioid Users

Poster Presenter: Avaas Sharif, M.D.
Co-Authors: Tarek Aly, M.D., Jessica Bayner, M.D., Asghar Hossain, M.D.

SUMMARY:

Drug overdoses killed over 60,000's individuals across America in 2016, with a quarter of these deaths stemming directly from heroin; this is a 500% increase from 2010. As opioid use and availability sweep the country, one of the demographics that is being drastically affected is the adolescent population. Naloxone HCL is a well-known antidote, acting as an antagonist for heroin overdose with great results if delivered promptly. With Naloxone HCL being available over the counter in over 40 states now, family and friends can save their loved ones with swift action if they are educated to identify signs of how opioid overdose presents. We have designed a step-wise process on how to build a self-sustaining Naloxone HCL education and distribution program for families and caretakers of adolescents to help minimize heroin overdose causalities. Program targets can be broken down into three categories and several subcategories including: 1) product-centric goals, which explore everything from how to acquire and administer Naloxone HCL; 2) client consolidation goals, which address how to identify adolescents who are at risk of overdosing, as well as how to connect with their caretakers; and 3) family and friend education goals, which entail the distribution of a specific curriculum, designed to educate patients' families and caretakers about signs of overdose and how to administer Naloxone HCl. The goals of this establishing such a program, in addition to the obstacles of creating it will be discussed in detail.

No. 99

A Retrospective Study of Mental Health in the Southern Appalachian Collegiate Population

Poster Presenter: Brittani Lowe

SUMMARY:

The purpose of this research was to investigate and describe Appalachian college students seeking psychiatric care, and in particular, to determine if such students differed from studies of students in other areas of the nation. Southern Appalachia is a rural location with limited mental health availability, as well as being immersed in an epidemic of opioid and other drug use disorders. Teenagers and young adults in Southern Appalachia do not have as much access to health care as similar populations in urban locations due to a number of factors (lack of transportation, poverty, lack of mental health professionals, stigma/cultural issues.) These factors may be significant enough to create differences in psychiatric profiles manifesting in college students in this area. Such information would be critical in planning for appropriate treatment and access to care. To our knowledge, no data exists regarding the psychiatric disorders and characteristics of college students seeking psychiatric care in this region. We conducted a retrospective chart review of 100 college students who sought psychiatric care from an on campus psychiatric clinic at a southern Appalachian university (Marshall University). Data including gender, age, race, marital status, year in college, past psychiatric history, history of suicide/homicide attempt, current suicidal or homicidal ideation, current psychiatric diagnosis, and substance use disorders was collected, entered into SPSS, and analyzed. The results and a review of the literature will be presented.

No. 100

How Does Culture Affect the Therapeutic Alliance? Patients' Perspectives on Their Therapists' Cultural Identity and Cultural Competencies

Poster Presenter: Steven M. Kam, M.D., M.B.A.
Co-Author: Elliot Feld

SUMMARY:

Background: Psychiatric research on patients of all ethnic backgrounds has demonstrated that a strong working alliance is associated with improved adherence to treatment recommendations and therefore improved outcomes. Working alliance is also positively correlated with therapists' cultural competency; providers who are more adept in cross-cultural relationships are more likely to foster stronger bonds with their patients. Much of the literature has examined therapists' self-reports of cultural competency with fewer studies considering patients' perspectives of their therapists' cultural competency. Generally these studies have failed to demonstrate significant agreement between therapist and patient perspectives of the therapist's cultural competency. As such, the current study explored patients' perceived cultural competency (PCC) of their therapists, as well as the perceived cultural similarity (PCS) between themselves and their therapists. We hypothesized there would be a positive correlation between PCC and working alliance and were also interested in exploring the possible influence of PCS on working alliance and PCC. Methods: Adult patients (18 years and older) with recent attendance at the outpatient psychiatry clinic at Albany Medical Center were offered the opportunity to be included in the study. Participants voluntarily completed questionnaires consisting of: (1) demographic information; (2) perception of cultural similarity between themselves and their therapists (a four-point self-rated item); (3) the Perceived Cultural Competency scale (PCC); and (4) the Working Alliance Inventory-Short Revised (WAI-SR). Patients were invited to complete their questionnaires before or after their appointments with a total time commitment of approximately ten minutes. The results were examined with SPSS statistical software using linear regression analysis. Results: We collected responses from a total of 119 patients. The demographic distribution of participants was predominantly White (68.4%), female (66.9%), and Christian (63.2%). The average length of treatment was 10.75 months. Preliminary analyses were consistent with our hypothesis and suggested a significant correlation between PCC and WAI-SR total scores ($r = 0.63$, $p < .01$). We also found a significant relationship between PCC and PCS ($r = 0.42$, $p < .01$). PCS and WAI were not significantly correlated ($r = 0.14$, $p = .16$). Conclusion: Therapists' cultural competency appears to be related to the working alliance which is in turn important for positive treatment outcomes. As our society continues to diversify, it becomes increasingly important to be aware of the influences of cultural similarities and competencies on the therapeutic relationship.

No. 101

Attitude Toward Seeking Professional Help for Mental Health Problems in a South Korean Population

Poster Presenter: Yungseo Ryu
Co-Authors: Soyoung Lee, Jung Han Yong, Shin Gyeom Kim, Jeewon Lee, SangWoo Han, Sehoon Shim, Doohyun Pak, EunJee Kim

SUMMARY:
Objectives : The primary objective of the present study was to examine the attitude toward seeking professional help for mental health problems and disclosing mental health problems to others among the general population in Bucheon city. The secondary objective of the study was to identify factors associated with the attitude toward seeking professional help for mental health problems. Methods : A total of 1,075 community-dwelling adults completed a self-report measuring willingness to seek professional help for mental health problems, willingness to disclose mental health problems to others, past history and family history of mental illness, frequency of contact with the mentally ill, awareness of stigma and discrimination toward the mentally ill, and the attitude toward the mentally ill using the Community Attitude toward the Mentally Ill (CAMI) scale. Participants were categorized into Help-Seeking Group and Non-Help Seeking Group according to their attitude toward seeking professional help for their mental health . Student's t-test, chi-square test and fisher's exact test were used to compare various variables between the two groups. Regression analyses were performed to examine the variables affecting the attitude toward seeking professional help. Results : 783(72.8%) participants reported being positive and 292(27.2%) participants reported being negative toward seeking professional help for their mental health problems. 270(25.0%) participants reported they would neither seek professional help for their

mental problems nor disclose their mental health problems to others. Help-Seeking Group had more family history of mental illness and more frequent contact with the mentally ill than the Non-Help-Seeking Group. In CAMI scale, Help-Seeking Group showed higher scores in authoritarianism and social restrictiveness and lower scores in benevolence and community mental health ideology. Regression analysis showed that subjects who had more awareness of the stigma and discrimination toward the mentally ill were more willingly to seek professional help for their mental problems (OR=2.485, 95% CI (1.638-3.769), p<0.001). Conclusion : Factors that facilitate and inhibit one's willingness to seek professional help for mental health problems should be further evaluated in different sites and demographics. Considering the factors associated with the attitude toward seeking professional help for mental health problems could increase effectiveness of public education efforts in the community to reduce barrier to mental health services.

No. 102

Perspectives on the Happiness of Community-Dwelling Elderly in Korea

Poster Presenter: Jinwoo Kim
Co-Authors: Sang Won Jeon, Kang-Seob Oh, Lee Ung

SUMMARY:

Objective: A community survey was performed to investigate the factors and perspectives associated with happiness among the elderly in Korea (?60 years). Methods: Eight hundred volunteers selected from participants in the Ansan Geriatric study (AGE study) were enrolled, and 706 completed the survey. The Happiness Questionnaire (HQ), which asks four questions about happiness, was administered. To explore the relationship between happiness and depression, the Geriatric Depression Scale (GDS) and the Beck Depression Inventory (BDI) also were administered. Results: The participants' average level of happiness, determined using a 100-mm visual analogue scale (VAS) of the HQ, was 64.7±26.0. The happiest situations for most people were "getting together with family" (23.8%) and "living in peace with family members (well-being)" (13.2%). Frequent reasons for not being happy were "worsened health condition" (28.7% of the not-happy group), "economic problems of their own" (16.5%), and "economic problems of their children" (14.8%). The participants' choices regarding the essential conditions for happiness were "good health" (65.3%) and "being with family" (20.5%). The BDI and GDS scores were negatively related to the happiness score. A preliminary scale (Happy (Haeng-Bok, ??) aging scale) based on the HQ for measuring the happiness level of the Korean elderly was suggested for follow-up studies. Conclusions: The most important factors determining the happiness of the community-dwelling elderly in Korea were good family relationships, economic stability, and good health. A higher depression score negatively impacted happiness among Korean elders. Further studies on the factors in their happiness are required.

No. 103

The Association Between Weekly Working Hours and Symptoms of Depression and Anxiety in Korean Employees

Poster Presenter: Jinwoo Kim

SUMMARY:

Objective : The aim of this study was to investigate the association between weekly working hours and symptoms of depression and anxiety in Korean employees. Methods : We studied 76,043 employees who attended annual health screenings in 2014. Weekly working hours were assessed with a self-reported questionnaire and categorized in one of 3 subcategories: <52, 52-59, and ?60 hour per week. Symptoms of depression and anxiety were assessed with the Korean version of the Center for Epidemiologic Studies Depression scale and the Beck Anxiety Inventory, respectively. We used multiple logistic regressions to calculate odds ratios for symptoms of depression and anxiety according to weekly working hours category, after adjusting for age, gender, marital status, education, smoking, alcohol consumption, sleep duration, occupational stress and either anxiety or depressive symptoms. Results : The prevalence rate for depressive and anxiety symptoms was highest at more than or equal to 60 h per week. The odds ratio for symptoms of depression and anxiety in groups of ?60 h was 1.147 (95% CI 1.036-1.271) and 1.231 (1.062-1.426) times higher than the reference group (<52 h per week).

Conclusion : Prolonged weekly working hours was associated with symptoms of depression and anxiety in Korean employees. The results of this study might help determine permissible working hours to protect employees from mental health problems.

No. 105
Efficacy of Vortioxetine in Patients With Major Depressive Disorder
Poster Presenter: Samuel Leopoldo Romero Guillena
Co-Authors: Beatriz Oda Plasencia García de Diego, Olalla Santamaria, Reyes Navarro, Francisco Gotor

SUMMARY:
Background: Major depressive disorder (MDD) is a prevalent cause of loss of productivity, early retirement and absenteeism in Europe, and will be a leading cause of disease burden worldwide by 2030. Vortioxetine is an antidepressant with a multimodal mechanism of action which effectiveness and safety profile were established based on a series of clinical trials. The main goal of this study was to assess the efficacy (control of symptoms and functionality) of Vortioxetine in the treatment of major depressive disorder. Methods: This is a prospective observational 8-week follow-up study in a real setting. Population of study: patients >18 years of age with a diagnosis of MDD (according to DSM5 diagnostic criteria) with a score on Montgomery-Åsberg Depression Rating Scale (MADRS) of > 20 points, without any other psychiatric comorbidity, who initiated adjusted-dose Vortioxetine treatment (5-20mg/24h) in monotherapy and provided informed consent. Efficacy variables: the primary endpoint was changes in MADRS score at the end of the study with respect to baseline score. Secondary endpoints include changes with respect to baseline values in the overall score for anhedonia as assessed using the Snaith Hamilton Rating Scale (SHAPS), and functionality as measured using the Sheehan Disability Scale (SDS) at the end of the study. Also, the proportion of responsive patients (defined as a decrease of > 50% of the overall MADRS score) and in remission (defined as an overall score of < 10 on the MADRS) Evaluations were performed at baseline, 2, 4, and 8 weeks. Student's t-test and Chi-square test were used to assess differences between baseline evaluation and subsequent visits. Statistical analysis was performed with SPSS 22.0 Results: A total of 66 patients were included in the study (44 female and 22 male). With a mean baseline score of 29.7 (±5.3) on the MADRS and 7.5 (±1.2) on the SAHPS. The baseline mean score on the SDS-Work was 7.9 (±1.3), 8.2 (±1.3) on the SDS-Social life and 8.1(±1.1) on the SDS-Family life. We observed a significant decreased in the total score on: MADRS scale (Delta=20.5 ±8.7; p<0.01). Such decrease started after 2 weeks on treatment. SHAPS scale (Delta=3.2 ±1.5; p<0.05). Such decrease started after 4 weeks on treatment. SDS-work scale (Delta= 4.9±1.6; p<0.01). Such decrease started after 2 weeks treatment. SDS-social scale (Delta=4.4 ±2.1; p<0.05). Such decrease started after 8 weeks on treatment. SDS-family scale (Delta= 3.9±1.7; p<0.05). Such decrease started after 4 weeks treatment At the study end, the mean treatment response rate was 68.18%, whereas the mean remission rate was 54.4%; with a rate of treatment adherence of 78.78% Conclusions: This case-series study demonstrates that Vortioxetine is effective in reducing the symptoms of depression, and improves functionality in patients with major depressive disorder. This study does not have potential conflict of interest.

No. 106
Age and Chronobiological Characteristics in Treating Depression
Poster Presenter: Sergejus Andruskevicius
Co-Authors: Violeta Meiner, Giedre Vindasiene

SUMMARY:
Objective – to study the influence of age for circadian rhythms of the parameters of spectral analysis of heart rate variability in the treatment of depression. Methods. 68 patients have been studied (ICD-10: F 31.3 - 31.4, F 33.0 - 33.2). Mean age 43.8±10.4 years. The patients have been divided into two groups: group 1 – 40 patients (age 19 – 49 years) and group 2 – 28 patients (age 50 – 70 years). Severity of depression was determined in accordance with HAMD-17, the level of anxiety – in accordance with HAMA. Assessing the autonomous regulation of the cardiovascular system the spectral analysis of heart rate variability was applied. The

power spectrum density (PSD) of LF (low frequency) and HF (high frequency) range was established. The patients were examined at 1 a.m., 7 a.m., 1 p.m., 7 p.m. prior to the beginning of treatment, at the end of the first week of treatment and at discharge from the hospital. In order to determine the daily curve of changes in the indices under investigation the control group (15 mentally healthy people, mean age 44.9±9.3 years) was examined at 1 a.m., 4 a.m., 7 a.m., 9 a.m., 11 a.m., 1 p.m., 3 p.m., 4 p.m., 5 p.m., 7 p.m. in summer. Results. The primary more pronounced features of desynchronisation for the middle age people (group 1) were characteristic in the night and in the morning hours, for the old aged people (group 2) – in the day hours. Group 1 already at the beginning of the therapy has experienced the resynchronisation features. In the group 2 the desynchronisation was getting stronger during the whole day. By the discharge the resynchronisation was more completed in the middle age group (group 1). Conclusions. The investigation data show the reduction of compensation possibilities for desynchronising circadian rhythms by aging in the treatment of depression.

No. 107

Social Pain: A New Clinical Construct in Psychiatry

Poster Presenter: Shavonne Julien-Huang, M.D.

SUMMARY:

Ms. H was a 23-year-old Chinese graduate student at an American University. She was first seen in the emergency department after being referred by her counselor at the graduate school. Ms. H reported that for the past year and especially the last six weeks she had increased depressive symptoms; a significant amount of weight loss, increased insomnia despite over the counter medication, uncontrollable bouts of crying, and suicidal ideation. The only child of a high-ranking physician and governmental servant, she reported that since high school she was under increasing amounts of pressure to succeed. It appeared that any achievements she did reach were met with disdain. Ms. H appeared driven to do well no matter the consequence to her mental health and physical well-being. She shared that she had also been self-harming for some time, describing the first time injuring herself accidentally and enjoying the sensation. She characterized the incident as one in which her mental pain was “perfectly imitated” by the physical pain. She often cut as a form of punishment for her self-perceived failures and feelings of isolation. She described the shame of not only her” cutting” behavior but of her perceived inability to succeed. She reported that no matter the accomplishment she continued to become more depressed and the self-injurious behavior became progressively worse. The patient did not have many friends in the US, except for her boyfriend who lived in different state, and therefore felt completed isolated. She described having no one to support her emotionally during this increasing depression. Given her reported suicidality, lack of self-care, and lack of social support Ms. H was admitted for an extended observation and started on a low dose of Mirtazapine. Social pain is a reasonably new construct with increasing neurobiological evidence to support it. It can be described as the perception of pain following episodes of isolation, feelings of poor support, and/or the loss of support. Recent research has shown that both the unpleasant (affective) component of physical pain and social pain lead to an increase in activity of the dorsal portion of the anterior cingulate cortex and the anterior insula. In the above case, Ms. H likens her overwhelming but invisible social pain to her physical pain; she experienced all the factors that would make up social pain, from being isolated from family to a lack of support. It can be postulated that the patient chose to replace her feelings of rejection with something tangible that she could control, the physical sensations of her “cutting”. Social pain is not a concept that is often used in the psychiatric lexicon at present however, it is clinically relevant. Physical pain perception can be modulated therefore it may be worthwhile to research how the experience of social pain can be modulated as well. Social pain could come to be part of a patient’s biopsychosocial formulation and thus, their treatment.

Differential Effects of Self-Harm and Chronic Pain on Pain Sensitivity in Patients With Depression: An Exploratory Analysis in a Convenience Sample

Poster Presenter: Srinivasa B. Gokarakonda, M.D., M.P.H.

SUMMARY:

Lead Author: Srinivasa Gokarakonda, MD, MPH Co Authors: Lakshminarayana Chekuri, MD, MPH; Jessica Carbajal, MD; Prasad Padala, MD; Pedro Delgado, MD; Ricardo Cáceda, MD, PhD. Background: Many individuals engage in Non-Suicidal Self Injury (NSSI) to gain relief from dreadful states of mind. NSSI is considered a way of externalizing emotional or psychological pain. There is evidence of decreased pain sensitivity (elevated pain threshold and tolerance) in patients with depression and suicidal and non-suicidal self-harm. It is hypothesized that NSSI and chronic pain have an additive effect on pain threshold elevation in depressed patients. Methods: This is an exploratory secondary analysis of data gathered from a voluntary convenience sample. One hundred and seventy individuals aged between 18 years and 65 years were recruited between January 2015 and April 2017 from mental health care inpatient units and ambulatory care settings. Individuals with a diagnosis of Major depressive Disorder, Bipolar Disorder and depression NOS and with a positive history of intentional self harm behavior and or chronic pain were recruited to groups 1-4. Group 5 consisted of 20 healthy individuals with no history of depression and chronic pain and intentional self harm behavior. Medial tibial pain pressure threshold algometry was measured by using a hand-held gauge with a 1-cm2 rubber tip. Standard clinical research measures such as Beck Depression Inventory-II (BDI-II), Beck Anxiety Inventory (BAI) and Columbia Suicide Severity Rating Scale(C-SSRS) were used to recruit individuals to the five groups. Analysis of variance (ANOVA) using SPSS 24 was used to compare continuous variables. Significant results were followed by Tukey's test. A general linear model was run with pressure pain threshold as dependent variable, presence of chronic pain and self harm as factors, and depression, self harm score, physical and psychological pain as covariates. Chi square tests were used to compare categorical data. Results: All four groups of individuals with a history of depression displayed higher pressure pain threshold when compared with healthy controls ($p = 0.024 - < 0.001$). Individuals with history of depression and comorbid history of intentional self harm behavior and chronic pain reported higher pain threshold when compared with other groups ($p<0.05$). Pressure pain threshold in depressed patients with either self harm or chronic pain alone were not different from depressed patients with neither self harm nor chronic pain. Depressed patients with a co-morbid history of self harm behavior and chronic pain reported higher pain threshold than other depressed groups ($p =0.004$) in this study. Conclusion: A history of intentional self harm behavior and chronic pain appears to have an additive effect on pain sensitivity in depressed patients.

Change of Electroencephalogram Complexity After Electroconvulsive Therapy in Patients With Severe Depression: A Multi-Scale Entropy Study

Poster Presenter: Weicheng Yang

SUMMARY:

Background: Electroconvulsive therapy (ECT) is an effective and rapid treatment for patients with severe acute major depressive episodes. However,its mechanism remained unclear. In a clinical cohort receiving ECT, we compared the change of electroencephalogram (EEG) complexity before and after treatment using multi-scale entropy method, and explored difference of multi-scale entropy profile between remitted patients and non-remitted patients. Methods: Patients with severe major depressive episode (either major depressive disorder or bipolar depression) (N=130) requiring ECT were recruited. ECT was performed for a maximum of 12 treatments. Symptom severity was evaluated with 17-item Hamilton Depression Rating Scale (HAMD-17). Conventional EEG was recorded before and after ECT treatment, multi-scale entropy of EEG signal was calculated and compared between before and after treatment, and between remitted and non-remitted patients. Results: Among 130 patients underwent ECT, 116 patients completed treatment, 61 patients completed pre-treatment and post-treatment EEG and were subjected to analysis. Both patients achieved remission and non-remission have significant lower sample entropy at finer time scale (1-2) after ECT treatment ($p<0.001$ for remission group in all brain area, but in non-remission group prefrontal area showed no change, $p=0.117$, all p-value are corrected for multi-comparison). Only

remission group showed significant increase of sample entropy at coarser time scale (9) at left parietal area (p=0.049). Spearman correlation coefficient is calculated for change in symptom severity (HAMD % change) and sample entropy change (% change). Decrease of entropy at finer time-scale (scale 2) is significantly correlated to symptom improvement at central (p=0.034), right lateral frontal (p=0.022), left parietal (p=0.037) and left centro-parietal area (p=0.041). Conclusion: In depressive patients receiving ECT, sample entropy of EEG decreased significantly at finer time scales, and the change was correlated with clinical severity. It is possible that brain activity randomness increased at left frontal, left centro-parietal and left parietal area during depressive episode. Such increase in randomness may reflect local connectivity disturbance, and was normalized after ECT. However, there were no healthy control data for comparison, and further study is needed. This study was supported by Kai-Kaohsiung Municipal Kai-Syuan Psychiatric Hospital, Kaohsiung, Taiwan.

Cross-Cultural Adaptation, Reliability, and Validity of the Revised Korean Version of Ruminative Response Scale

Poster Presenter: Won Kim

SUMMARY:

Objective Rumination is a negative coping strategy defined as repetitive and passive focusing on negative feelings such as depression. The Ruminative Response Scale (RRS) is a widely-used instrument to measure rumination, but there is continuing argument about the construct validity of the RRS, because of probable overlap between the measurement of depression and that of rumination. The RRS-Revised, which removed 12 items of the RRS, is suggested as a more valid instrument for measuring rumination. Therefore, we translated RRS-R into Korean and explored the reliability, validity and factor structure in patients with major depressive disorders. Methods Seventy-nine patients with major depressive disorder took the Korean version of RRS, RRS-R, State Trait Anxiety Inventory, Beck Depression Inventory and Penn State Worry Questionnaire. We performed exploratory factor analysis of RRS-R, and tested construct validity, internal reliability and test-retest reliability. Results The internal and test-retest reliability of RRS-R was high. Factor analysis revealed that RRS-R is composed of two factors. 'Brooding' factor explained 56.6% and 'Reflection' factor explained 12.5%. RRS-R, especially 'Brooding factor', was highly correlated with other clinical symptoms such as depression, anxiety and worry. Conclusions In this study, we find out the RRS-R is more reliable and valid than the original RRS in Korean patients with depression because the RRS-R is free from the debate about the overlap of item with BDI. We also revealed that 'Brooding' is highly correlated with depressive symptoms. RRS-R may be a useful instrument to explore the implication of 'Brooding' in depression.

Association of Dopaminergic Polymorphisms With Cerebral Blood Flow in Psychomotor Retardation of Depression

Poster Presenter: Yingying Yin

SUMMARY:

Background: Several lines of evidence implicate dopamine is involved in the psychomotor retardation (PMR) in major depressive disorder (MDD). The cerebral blood flow (CBF) of PMR is also well investigated, which found abnormal CBF mainly in the cortico-basal ganglia-thalamo-cortical (CBTC) circuitry. We hypothesize that the polymorphisms of the dopaminergic pathway should be associated the abnormal CBF in the CBTC circuitry. Objective: To investigate the association of the polymorphisms throughout the dopaminergic pathway with the cerebral blood flow (CBF) of PMR in MDD. Methods: 107 antidepressant-free MDD patients were divided into PMR group (N=72) and NPMR (non-PMR) group (N=35) according to the Salpetriere Retardation Rating Scale (SRRS) score and underwent resting-state Arterial spin labeling magnetic resonance imaging (ASL-MRI). The ASL data were collected respectively for the CBF and calculation. The blood sample of 63 patients (23 PMR, 40 NPMR) were collected for genotyping the dopaminergic polymorphisms (92 SNPs from10 genes). After quality controlling, 15 SNPs in 8 candidate genes were entered into the mass univariate modeling analysis. For the statistical analysis, patients with

unqualified fMRI image and unmatched demographic data were ruled out. Consequently 56 patients (23 PMR, 33 NPMR) were taken into the statistical analysis. Results: Genotype-by-PMR associations with the CBF differences were identified for 7 SNPs with the lowest significant P values. The brain regions predominately distributed in bilateral prefrontal cortex (PFC), temporal cortex, and striatum, the left thalamus, the right primary motor cortex, insular cortex, fusiform gyri, and lingual gyri. The distribution of the significant brain region was similar in these genes. The genotype-by-PMR interactions at the CBF of these brain regions were also similar. The minor allele of DRD3_rs 6280 and SLC6A3_rs6347, and the major allele of other SNPs significantly increased the CBF. There were significant negative correlation between the CBF of the PFC and the PMR severity. However, the CBF of the striatum and the thalamus were positively correlated with the PMR severity. Conclusions: The polymorphisms of dopaminergic pathway are associated with not only CSTC circuitry, but also some other brain regions involving in cognition and emotion controlling. The minor alleles of DRD3_rs 6280 and SLC6A3_rs6347, and the major alleleminor allele of other dopaminergic polymorphisms might play a protective role in PMR. While the increased CBF of PFC might suppress PMR, the increased CBF of striatum and thalamus adversely aggravate PMR.

Meningioma and First-Time Onset Depresive Epsiode

Poster Presenter: David Schwartz, M.D.
Co-Author: Asghar Hossain, M.D.

SUMMARY:

Introduction: Meningioma – a tumor, usually benign, slow-growing, arising from meningeal tissue of the brain. This is common type of tumor that originates in CNS. The prevalence of pathologically-confirmed meningioma is estimated to be approximately 97.5/100,000 in the United States with over 170,000 individuals currently diagnosed with this tumor. Relatively big sizes of meningioma determine the brain damage by “pressure like” effect and consequently neuropsychological changes in patients. Objective:The objective of this article is to report a case of depression with meningioma and emphasize the reasons why these psychological changes occur. Discussion: There are studies which show correlation between brain tumor and depression. Because most meningiomas grow very slowly, symptoms often develop gradually, if they develop at all. Most common symptoms are: worsening headaches, mood disturbances, seizures, blurred vision, weakness in arms and legs numbness, speech problems. Pressure-like effect or “disconnection” of interrelated brain areas can cause significant problems. It is important to estimate brain tumor size and type in terms of developing symptoms. .Another important biological mechanism of depression is stress-related hyperactivity of the hypothalamic-pituitary-adrenal (HPA) axis. Chronic stress significantly diminishes feedback inhibition of glucocorticoid-induced reduction of HPA axis and thereby increases corticotrophin-releasing hormone (CRH) secretion. As a result expression of proinflammatory cytokines, including tumor necrosis factor-? (TNF-?), interleukin-1 (IL-1), interleukin-6(IL-6), is the main underlining mechanism of clinical

Does the Aftermath of 9/11 Still Exist? Delusional Disorder Versus PTSD After 9/11

Poster Presenter: David Schwartz, M.D.
Co-Authors: Asghar Hossain, M.D., Javeria Sahib Din

SUMMARY:

Background The 9/11 terrorist attacks shook the persons residing not only in New York but also those living outside USA. In initial evaluations, it was estimated that approximately 500,000 persons will develop PTSD following the event. Volunteer organizations reported stress reaction and adjustment disorder as the most common reported symptoms. Difficulty concentrating, difficulty sleeping, re-experiencing the event, nightmares etc. were some prevalent symptoms reported. Methods Literature on psychosis and use of psychotropic medications after 9/11 is reviewed from 2001 onwards. Database used is PubMed and Cochrane. Objective There is extensive data on PTSD after 9/11 incident, but little is known about association of a national catastrophe with psychosis or delusions. In our paper, we have discussed cases of psychosis reported after 9/11 incident. Hence, the purpose of

this review is to determine a positive correlation, if any, between psychosis and traumatic life event. Conclusion We found a positive correlation between traumatic life events and psychosis. From literature review, we found cases reported for psychosis after the 9/11 incident. There was an increase in the dosage of psychotropic medications used in NYC after the terrorist attack. Those patients who had a history of psychosis, developed delusions following the event. Australian inpatient hospital survey reported an increase in delusions in psychiatric patients after watching media footage of the incident. Hence, our patient possibly suffered from delusional disorder secondary to the trauma related to 9/11 attacks.

An Atypical Presentation of Trauma in an Older Patient

Poster Presenter: Ayotomide E. Oyelakin, M.D., M.P.H.
Co-Authors: Oluwole Jegede, M.D., Alexander Maksymenko, M.D., Ayodeji Jolayemi, M.D., Tolulope A. Olupona, M.D.

SUMMARY:

Introduction: Older patients who have experienced trauma in earlier years tend to present differently compared to the younger age group. The elderly population is expected to exceed 70 million by 2030 necessitating the need for in-depth understanding of the sometimes different clinical presentation of symptoms of posttraumatic stress disorder (PTSD) in that population. Trauma in the elderly is complex and often complicated by the presence of comorbid psychiatric diagnoses which may mask the way such cases present clinically. Role changes and functional losses including physical and cognitive impairments could also make coping with memories of trauma in earlier life more difficult for aging patients, and impact the way they present to the clinician. Case Summary: We present a case report of a 75-year-old African American female patient who was initially diagnosed with Schizoaffective disorder four years before her current presentation. At presentation, the patient appeared psychotic, and was disorganized in her speech and thought process. On further psychiatric evaluation, she revealed a past history of multiple trauma including rape, gunshot injury and traumatic loss of a grandchild. Most significant, she reported re-awakened memories of an incident of a rape 54 years ago which triggered her current acute presenting symptoms. Evaluation revealed that these symptoms were triggered by a smell and that led to the deterioration in her mental state. Patient had a strong avoidance of emotions and suppression of feelings preferring not to discuss her re-experiencing symptoms. The patient scored 20 on the PCL-S PTSD Checklist, 20 on Mini-mental State Examination (MMSE) and 16 on the Montreal Cognitive Assessment (MOCA). During the course of admission, the patient was initially placed on Haloperidol 4mg daily which was discontinued when she was diagnosed with Trauma related disorder. Sertraline 25 mg PO daily was prescribed with good response and resolution of presenting symptoms. Discussion: It is of note that in elderly patients like our patient, the clinical presentation might not meet the DSM-V criteria for PTSD; however, remembering or reliving the trauma could cause considerable distress and present as some other psychiatric illness such as psychosis, major depression, and severe anxiety. This brings to play the importance of a thorough history and evaluation in ruling out other psychiatric diagnoses from trauma related disorders in elderly patients. Conclusion: There is limited available literature on the presentation of trauma in older adults who have had traumatic experiences at an earlier age. Symptoms of past trauma in the this group of patients may be delayed and may show atypical features leading to a challenge in diagnosing as patients often present with symptoms suggestive of other psychiatric illness. A thorough evaluation and exploration of the past psychiatric history is imperative for a definitive diagnosis and effective management.

Bariatric Surgery Complications and Posttraumatic Stress Disorder: A Case Report

Poster Presenter: Shivnaveen Bains, M.D.
Co-Authors: Kanwalnaveen Bains, M.D., Rochaknaveen Singh Bains, M.D.

SUMMARY:

INTRODUCTION: There is very limited data available describing the impact of bariatric surgery complications on patient's mental health and risk of

developing Post traumatic stress disorder. In this case report we explore the relationship between bariatric surgery complications and PTSD. CASE: We present a case of a 56 y/o female with h/o HTN, GERD and depression s/p Gastric Bypass surgery for weight loss who presented to Visceral Inflammation and Pain Center for psychiatric evaluation. Patient had GBP surgery in 2008 and was eventually diagnosed with distal esophageal diverticulum for which she had a prolonged hospital stay in relation to laparoscopic diverticulectomy with conversion to laparotomy, lysis of adhesions, revision of prior gastric bypass. However, she developed complications which resulted in spleen injury requiring splenectomy and multiple surgeries for subsequent infections and endured 14+ surgeries which significantly decreased her quality of life. Patient reported h/o nightmares at night and flashbacks accompanied with hypervigilance and avoidance of hospitals. On examination, she reported her mood as sad and depressed with blunted and tearful affect, she appeared hopeless about her future and expressed feeling of guilt but denied any SI/ HI. She was diagnosed with MDD, single episode severe without psychotic features and Posttraumatic stress disorder from medical traumatization. Patent's depression was managed with Celexa 40 mg once a day, Wellbutrin 75 mg BID and prazosin 2 mg QHS for nightmares at night and Cognitive behavioral therapy. DISCUSSION: Adequate psychiatric follow after the surgical procedure is necessary to enable a long-term stabilization of patients with mental co-morbidities. Dietary regimens before and after bariatric surgery often create the perfect environment for serotonin depletion and makes patients vulnerable for worsening of depression. Post-operatively, patient's diet is limited to protein and supplements to prevent vitamin and muscle mass. Post-operative complications of GBP surgery can lead to significant mental trauma progressing to PTSD and worsening of depression. CONCLUSIONS: Furthermore, longer studies are needed to better define whether bariatric surgery has a positive or negative effect on the mental health of patients and to study the impact of surgical trauma. No doubt most bariatric surgery programs require pre-operative psychiatric evaluation, this case shows the importance of regular post-operative psychiatric follow up and considering PTSD as differential diagnosis.

Posttraumatic Stress Disorder in Raped Victims: Applicability of Interpersonal Psychotherapy
Poster Presenter: Cecília Roberti Proença, M.D.
Co-Authors: Andrea Feijo-Mello, M.D., Ph.D., Euthymia Prado, Thays Mello Ferreira Milan, Janaina Cruz, Luciana Nóbrega, Mariana Maciel, John C. Markowitz, M.D., Marcelo Mello, M.D., Ph.D.

SUMMARY:
Background: An estimated 18% of women suffer sexual abuse during their lifetime. Among them almost half develop posttraumatic stress disorder (PTSD) following the trauma. Prolonged Exposure Therapy (PE), a technique of cognitive behavior therapy is considered the most efficacious treatment but has high rates of dropout. Markowitz et. al proposed that a non-exposure therapy as Interpersonal Psychotherapy (IPT) adapted to the treatment of PTSD (IPT-PTSD) might have similar efficacy and better adherence. **Objective:** The aim of this study is to assess the applicability of IPT for the treatment of women with a confirmed diagnosis of PTSD between one and six months after being raped. **Methods:** The present study was initiated in October 2015, and it will enroll patients until 2018. In this two arm randomized controlled clinical trial raped victims who developed PTSD are receiving IPT-PTSD or sertraline delivered as standardized treatment. Sample: A subsample of 24 patients who received IPT-PTSD was analyzed. Four trained psychotherapists applied IPT-PTSD ("Treatment Manual: IPT for PTSD" (reproduced with permission of the authors). Sessions were supervised by expert IPT psychotherapists and recorded to certify therapy quality. Instruments: To confirm the diagnosis of PTSD and assess the evolution of symptoms of PTSD, anxiety and depression, the following instruments were used: MINI (Mini International Neuropsychiatric Interview); Clinician-Administered PTSD Scale (CAPS-5), Beck Depression Inventory (BDI) and Beck Anxiety Inventory (BAI). **Results:** Until this moment, nineteen out of twenty-four patients

completed the IPT treatment. The dropout rate was 16,6%, while the absenteeism rate was 22,8%. Women who received IPT experienced significant reduction in PTSD (p=0,001), depressive (p<0,001) and anxiety (p=0,002) symptoms. **Discussion:** This may be the first formal study of IPT for PTSD specifically due to sexual trauma. It is possible that IPT, focusing on feelings to help patients understand relationships, may fit raped victims particularly well. Dropout rates from PE usually range from 10–44%, so our findings suggest that IPT could be an interesting alternative therapy for this group of patients.

No. 118

Posttraumatic Stress Disorder in an Adolescent With Inflammatory Bowel Disease-Related Medical Trauma

Poster Presenter: Deepan Singh, M.D.
Co-Author: Surinder Moonga

SUMMARY:

The incidence of Post-Traumatic Stress Disorder (PTSD) after bowel surgery for Inflammatory Bowel Disease (IBD) has not been well described in the literature. This could be due to low incidence or lack of recognition amongst patients and clinicians. This report describes a fifteen-year-old female with a past medical history of Crohn's disease who presented with dissociative symptoms. These episodes were recognized to be a symptom of underlying PTSD from medical trauma related to IBD. To confirm, the Child PTSD Symptom Scale (CPSS) was administered, with higher scores indicating greater functional impairment. On initial presentation, her Part 1 score was 41 (max 51, min 0) and Part 2 graded YES 6 NO 1. In particular, her symptoms of hypervigilance, avoidance and negative alterations in both mood and cognition stood out. She was treated with sertraline, gradually increased to a dose of 100mg, and Cognitive Behavioral Therapy (CBT). The CPSS was administered again after two months of her treatment. Her Part 1 score was 21 with Part 2 graded YES 3 NO 4; this signaled significant improvement and remission from PTSD. The patient's depersonalization events have completely resolved along with her nightmares and hypervigilance. Over six months from initial presentation, the patient remains in remission from PTSD symptoms. Surgery is generally not considered trauma in the eyes of the clinician, though it may have a lasting effect on younger populations. Multiple physicians, and even a mental health professional, did not consider PTSD in this patient given the lack of exposure to "classically" traumatic experiences (violence, rape, war, etc.). Thus, it is likely that patients with similar presentations to our patient may go undiagnosed if not screened for the possibility of PTSD. If diagnosed earlier, this patient could have avoided life-impairing emotional distress as well as expensive medical workup. Although post-surgical PTSD in adolescents has not been commonly reported, screening patients for psychiatric pathology after bowel surgery could potentially avoid life-impairing emotional distress in patients with IBD.

No. 119

Ketamine and Mindfulness Therapy in PTSD Treatment

Poster Presenter: Esther Bilenkis, D.O.

SUMMARY:

Introduction: PTSD is a debilitating disease which has been found very difficult to treat and has a high relapse rate after treatment. TIMBER, or Trauma Interventions using Mindfulness Based Extinction and Reconsolidation for trauma memory has been shown to be an effective, personalized treatment for eliminating PTSD and when combined with ketamine, results are evident within four hours. Ketamine is the only pharmacological agent whose mechanism of action allows results within hours. This property lends to its great benefit in treatment of serious psychiatric disorders such as PTSD. Case Report: We present the case of a Biracial female who has been discharged from our care. Her PTSD has been cured and she is maintaining well at 7 months after discharge and returned to work. She suffered from SLE, PTSD from physical and sexual trauma, throughout no medication. Her treatment included just one infusion of ketamine and 12 face-to-face sessions of TIMBER and home practice sessions daily twice and as needed Conclusions: Ketamine and TIMBER leads to rapid treatment of PTSD. The rapid-acting Ketamine and the reinforcement with TIMBER leads to long-lasting results and allows the patient to return to life before the illness.

No. 120

PTSD Severity and Demographic Comparison in a U.S. Active Duty Military Population

Poster Presenter: Joseph Mansfield, D.O.
Co-Author: Christopher Jorgensen, M.D.

SUMMARY:

Background: Posttraumatic stress disorder (PTSD) has become a growing mental health concern with nearly 1 in 12 Americans having a change to be effected by it in their lifetime. In the military population, the change of being effected is much higher, nearly double that of the civilian population. This study investigated the relationship between PTSD and demographics in a sample of active duty U.S. military members presenting for inpatient psychiatric hospitalization. Objective: To compare PTSD severity in an active duty military population in regards to the gender, race and age of the participants. Methods: A de-identified database of psychiatric inpatient information was used to investigate a relationship between the PTSD Checklist-Civilian (PCL-C) and the subjects' gender, race and age. The subjects were adults (18-50). Inclusion criteria included admission to the San Antonio Military Medical Center inpatient psychiatric ward and an ability to complete psychometrics. Results: Psychometric and demographic data of 314 U.S. Military patients over a span of 9 months revealed a mean PCL-C score range of 31.82-51.06. The PCL-C aggregate scores were found to be higher for males, Hispanics and age over 30 for gender, race and age respectfully. However when reviewing the 95% confidence interval range, the only demographic marker that approached statistical significance was age over 30. Conclusion: Increased age (>30) in the target population did show a significant increase in PTSD symptoms over those in the younger age ranges (<18 and 19-21). No other demographics showed statically significant differences in their scores. Need for better understanding of the interaction between gender, race and age to help better understand their role in development of PTSD symptoms is required.

No. 121

Neurobiology and Transmission of Trauma: A Literature Review of the Biologic and Cultural Expressions of Transgenerational Trauma

Poster Presenter: Kimberly Stubbs, M.D.

SUMMARY:

Clinicians, therapists, and researchers alike have explored the effects of trauma that is transferred from a first generation of trauma survivors to second and further generations of offspring of the survivors. This type of historical trauma is frequently referred to as transgenerational trauma, intergenerational trauma or a subtype of Post-Traumatic Stress Disorder (i.e. post traumatic slavery disorder, post traumatic slave syndrome) in professional literature. Identifiable groups of persons effected by intergenerational transmission of trauma include African Americans, American Indians, and the family members of Holocaust survivors and War Veterans. These groups will be used to illustrate the residual effects of trauma for the purposes of this poster but is not an exhaustive list. Trauma is a relatively common chief complaint and/or precipitating factor seen by Mental Health clinicians and therapists. However, professionals continue to grapple with the intersection of neurobiology and an environment characterized by significant historical trauma. Common questions raised during the study of this intersection include: "What conscious or unconscious processes are involved in the transmission of trauma? Are there epigenetic factors? What are the clinical implications of historical trauma?" Incorporating knowledge of the hypothalamic pituitary adrenal axis in the response to stress and including a transcultural framework, researchers are addressing each of these questions. The purpose of this literature review is to discuss the neurobiology associated with trauma and clinical methods that will likely prove useful for understanding and transforming the impact of historical trauma.

A Case of Drug Rash With Eosinophilia and Systemic Symptoms (DRESS) Associated With Valproic Acid and Olanzapine

Poster Presenter: Lee Ung
Co-Authors: Sang Won Jeon, Kang-Seob Oh, Jinwoo Kim

SUMMARY:

Drug rash with eosinophilia and systemic symptoms (DRESS) syndrome is potentially life-threatening, medication-induced hypersensitivity reaction with long latency. It is characterized by fever, rash, leukocytosis with eosinophilia, atypical lymphocytosis, and internal organ involvement. The most common causes of DRESS syndrome is sulfonamides and anticonvulsants such as carbamazepine, lamotrigine. However, valproic acid and olanzapine could develop DRESS syndrome. We report a case of DRESS syndrome associated with valproic acid and olanzapine in 41 years old male patients with bipolar disorder.

No. 123

Natural Course of Posttraumatic Symptoms in Late-Adolescent Maritime Disaster Survivors: Results of a 12-Month Follow-Up Study

Poster Presenter: Lee Ung
Co-Authors: Sang Won Jeon, Kang-Seob Oh, Jinwoo Kim

SUMMARY:
This study is a prospective observational study on 75 late-adolescent survivors of a large passenger ship accident from immediately after the accident to one year later. Assessments of student survivors were conducted on day 2 and at months 1, 6, and 12. The PTSD Checklist (PCL), Patient Health Questionnaire-9 (PHQ-9), State subscale of the State and Trait Anxiety Inventory (STAI-S), Athens Insomnia Scale (AIS), and Brief Resilience Scale (BRS) were administered. When the assessments for day 2 and month 12 were compared, all the scales, except the PCL-avoidance subscale, showed a significant improvement in symptoms among males. However, among females, all the scales, except the PCL-re-experience subscale and the STAI-S, failed to show a significant improvement. All the symptoms for both males and females showed a pattern that decreased to the lowest level at month 1 (mandatory camp treatment period), then increased at months 6 and 12 (voluntary individual treatment after returning to school). The rapid deterioration of psychological symptoms was found during the chronic phase, when students returned to their daily routines and received voluntary individual therapy. There is a need to screen high-risk adolescents and be more attentive to them during this period.

No. 124

Analysis of Big Data From a Hospital Shows Haloperidol With an Increased Level of Serum Total Cholesterol

Poster Presenter: Jai Sung Noh

SUMMARY:
Background: The quality of medical information has been dramatically improved since the introduction of the electronic medical record system (EMR). Along with large sample sizes, the EMR system is not only easy to operate, but can also generate clinically relevant data with high quality without selection bias. Association of antipsychotics with metabolic syndrome is well known especially in atypical antipsychotics. Increased serum lipid level has been associated with antipsychotic treatment especially clozapine or olanzapine [1]. Haloperidol, a butyrophenone series of typical antipsychotic has been widely used for the treatment of schizophrenic disorders and other disorders with psychotic symptoms in psychiatric cares. Haloperidol has been known to have better serum lipid level effect than atypical antipsychotics. Here we tested the dyslipidemic effect of haloperidol using EMR data. Methods: We used a clinical database of an affiliated hospital [2] with a medical school located in Suwon, South Korea. Since its opening in 1994, this hospital has adopted the EMR system, which digitally collects and distributes patients' data to all of the departments in the hospital. The dataset used in this study is derived from this database with information such as admission, discharge, diagnosis, prescribed drugs and selected laboratory data for the period 1 June 1994 to 31 July 2013. This database contains information of total 461,170 patients with 4,920,758 prescriptions and 189467423 laboratory data. Extracting a dataset from this database to compare the levels of serum total cholesterol level before and after haloperidol usage. Results We selected 304 cases of data, 70% were males and mean age of the patients was 53 +/-17 years old. The levels of serum total cholesterol before and after haloperidol usage were 107 +/- 48.4 and 116 +/- 44.5 mg/dL respectively, and paired t-tests revealed that total cholesterol levels were significantly different (<0.05). Conclusion: Findings showed that an exposure to haloperidol could lead to an increase in levels of

serum total cholesterol. This suggest tha haloperidol would increase the risk of developing diabetes and coronary heart disease. Future study will be needed to discriminate direct and indirect effects of haloperidol on cholesterol level. Also we suggested that EMR data can be a valuable tool to investigate the effects of treatment on several clinical data.

No. 125

Unable to Regret: Travelling to Mexico Results in Lobotomy Performed Without Consent on Patient With Schizophrenia

Poster Presenter: Khalid Salim Khan, M.D.
Co-Author: Davin A. Agustines, D.O.

SUMMARY:

Background: Surgical intervention to treat serious mental illness is a topic that is shaded by a dark historical context. While psychosurgery for schizophrenia enjoyed increasing popularity during the early 20th century, it eventually fell out of favor due to the advent of effective antipsychotic medications. In countries where the informed consent process is not consistently used, however, patients can be subjected to invasive procedures without understanding what they entail. Numerous reports exist in non-scientific literature detailing forced lobotomy procedures that have occurred to patients living in various developing countries. Methods: Using a PubMed search, we found a single case of a patient with schizophrenia that had undergone prefrontal lobotomy in recent scientific literature (Kumagai 2016). We report on a case of a male diagnosed with schizophrenia, who while travelling to Mexico had a bilateral anterior capsulotomy performed without his consent. Results: Collateral information indicated that the patient had “bloqueo therapia” performed in Mexico. The patient and his family, however, were unsure of what procedure he had undergone. A subsequent CT scan of the head revealed findings indicative of an anterior capsulotomy or lobotomy procedure. Of particular note, the patient was persistently fatigued throughout the hospital admission, a symptom which has been correlated with the capsulotomy procedure. Discussion: The patient developed a known apathy syndrome, as well as tiredness from the procedure performed. His positive symptoms of psychosis remained, and required adequate treatment with Risperdal to minimize their intensity. As the utilization of psychosurgery for schizophrenia is essentially nonexistent in the US, it is important to realize that psychiatric interventions as well as the informed consent process may vary greatly in other countries when compared to the United States. Conclusion: Obtaining a detailed history of treatment approaches in patients that have received mental health services abroad can aid diagnostic formulation. It is important to recognize that negativism in schizophrenia with patients that have travelled abroad and received mental health services may be due to apathy secondary to psychosurgical procedures.

No. 126

Responsiveness of Depression to Parathyroidectomy in a Patient With Primary Hyperparathyroidism: A Case Report

Poster Presenter: Khalid Gamal Shehatto, M.B.B.S.

SUMMARY:

The incidence of primary hyperparathyroidism (PHPT) is about 21 cases per 100,000 person-years and is usually caused by a solitary parathyroid adenoma. Patients suffering from hyperparathyroidism may display a range of neuropsychiatric symptoms, including depression, anxiety, behavioral disturbances and psychosis, and reduced neurocognitive function. The diagnosis of pHPT may easily be missed if not suspected by the clinician and if the appropriate biochemical tests are not performed. The pathogenesis of psychiatric symptoms in PHPT remains unclear. Several studies suggest that surgical removal of the parathyroid adenomas may result in a clinical improvement of psychiatric symptoms. We present a patient with pHPT and treatment-resistant depression, where the level of calcium was in the normal range. His symptoms decreased in severity after surgery, and complete remission of symptoms on escitalopram. Our discussion of the case is placed in the context of the recent literature review on the topic of pHPT and neuropsychiatric symptoms. Mr. A, a 35-year-old man with long and recurring periods of depressive symptoms since the age of 12. He had recurring suicidal thoughts and one suicidal attempt using organophosphorus insecticide ten years ago.Most of

the antidepressants were tried including drug combinations beside ECT with partial response. He was on escitalopram 20mg od and duloxetine 60mg od. On early 2017, He developed acute anginal pain after which he was admitted for investigations, then he was diagnosed as pHPT and met criteria for parathyroidectomy.he was operated on February 2017. His depressive symptoms severity decreased with time. Currently, he is using escitalopram 10mg tab od with complete remission.

No. 127

Graves Disease-Induced Psychosis

Poster Presenter: Meelie Bordoloi, M.D.

SUMMARY:

Graves disease induced psychosis Co-authors Ravi Shankar, MD., Garima Singh, MD. Abstract We present a rare case study of a 44 y/o African American female who presented to the outpatient clinic with increased paranoia and auditory hallucinations. She reported that she was doing well in life until suddenly she started hearing voices on a Sunday afternoon in the month of March 2015 and within a period of 1-2 day she started hearing the voices all the time. There were multiple people talking inside her head. She reported that she was incapable of doing anything, she was unable to read, watch TV, had to quit her job in home health. She indicated that it limited her life so badly that she sought medical attention; her primary care physician started her on Olanzapine 2.5mg and referred her to psychiatry. She also had olfactory hallucinations including smelling perfumes and cooking odors that were not there, she had an MRI brain and EEG, which were unremarkable. She reported some response from the olanzapine but stated that she was scared to leave her house, felt that people were after her; they were plotting against her and her children. She has an adolescent child with developmental disability and she is the sole care giver to him and so did not want to go to the hospital and stated that she could take of herself. She also had some support from her church group. We titrated the olanzapine further to 10mg with some relief to the symptoms and did the basic lab work including TSH. Her vitals at the initial appointment were grossly normal other than mild tachycardia. Labs showed suppressed TSH, normal T3 and elevated free T4. On further evaluation, she also reported a one-month history of a chronic throat discomfort but otherwise denied any skin or hair changes, palpitations, diaphoresis, or hand tremor. She did not have gastrointestinal disturbances. Her energy level and mood had been stable. She noted occasional dry eyes with her contact lenses; no diplopia or other visual disturbances. She was referred to endocrinology for further management, they did a thyroid ultrasound, which was normal, but the RAI scan showed diffuse uptake indicating graves disease. So, she was started on Methimaxole 20mg for the hyperthyroidism. At the next follow up visit with the psychiatrist patient reported that she has been doing much better. She did not hear any voices for last 1 month. She has been back to school, looking for a job and reported that she has been able to focus, concentrate and take care of herself. Denied any side effects from the medication. The case we managed reminds us that psychiatric disorder can be manifestation of an endocrine disease and the importance of medical workup and physical examination in the course of treatment of mental disorder.

No. 128

Treatment of Agitation Associated With Hypoglycaemic Encephalopathy: Case Report and Literature Review

Poster Presenter: Muniza Majoka, M.B.B.S.
Co-Authors: Ramaswamy Viswanathan, M.D., D.Sc., Paulo Marcelo Gondim Sales, M.D.

SUMMARY:

Background:Hypoglycemia can lead to different symptoms ranging from diaphoresis, tachycardia, anxiety leading up to altered mental status, coma and convulsions [1], which characterize the presentation of hypoglycemic encephalopathy. Permanent neuronal damage can occur in the brain leading to due to varying severity and length of hypolycemia [2] The mechanism of brain injury in the brain secondary to prolonged and sever hypoglycaemia involves the increased level of extracellular glutamate, an alternative source of energy, which then leads to excitatory neurotoxicity and neuronal death by increasing intracellular calcium levels. Here we report the successful use of escitalopram in the treatment of agitation after

hypoglycemic encephalopathy that did not respond to treatment with other medications.Case Report:A 26-year-old gentleman with a history of insulin dependent Diabetes Mellitus, Hypertension, Stage 4 chronic kidney disease multiple previous episodes of profound hypoglycemia and poor glucose control on insulin pump presented to our emergency department after being found unresponsive in bed with a blood glucose level of 40 mg/dl and a GCS score of 7. He was intubated for airway protection and sedated initially with propofol and later with dexmedetomidine infusion. He was non-verbal with poor attention, disoriented and agitated with GCS 9 after extubation. Haloperidol and risperidone were use but led to ECG QTc prolongation and had to be discontinued, valproic acid and lurasidone had unequivocal effects. Over the next few weeks, he regained some verbal capacity but continued to be inattentive, disoriented with poor impulse control and agitated behaviour. He was found not to have decisional capacity and was maintained on constant observation for safety. The patient was then started on escitalopram 10 mg OD. Within the next two weeks of treatment, the patient's agitation episodes decreased dramatically and albeit resolved. He also began show continually improved mentation and cognitive function as well as improving language skills. Although he was not able to regain function at premorbid baseline,he continued to show good impulse control and lack of agitation during the rest of his 8-month long hospital course. Literature review & Discussion:A literature search was carried out on MEDLINE,Ovid as well as google scholar databases using different word combinations. No studies on the management of agitation or neuropsychiatric symptoms in a case of hypoglycaemic encephalopathy were found. Guidelines support the use of beta blocker, propranolol in particular, for agitation [3],questionable long term sequalae of Haloperidol use are reported,[4] while Risperidone use is reported with good effects[5] Use of antidepressants such as sertraline and citalopram has shown good results in patients with TBI.[6] Conclusion:Given the lack of serotonergic transmission post-brain injury,[7] SSRIs have a role in treatment of agitation that needs further resea

No. 129

Efficacy, Pharmacodynamics, and Correlated Neuroimaging Regarding Psychedelics: A Literature Review

Poster Presenter: Mustafa Kaghazwala, D.O.

SUMMARY:

Hallucinogens have a cultural basis among societies world wide due to their ability to allow the user to experience a reality not bounded by normal wakeful consciousness. These drugs were even used in clinical practice in the united states until their clinical significance was questioned which resulted in criminalization of use and consequent cessation of research. As our scientific understanding of the brain has advances, unfortunately there has not been a major therapeutic breakthrough treating depression, anxiety, and related mood disorders. Although there is limited data to draw on, this review will look at the comparative efficacy of mescaline, ketamine, LSD, psilocybin, Ayahuasca, and other psychedelics. This review will also explore the proposed effects of psychedelics on the serotonergic and glutaminergic systems; both of which are continually being researched to ameliorate symptoms of mood disorders . Lastly, clinical trials involving neuroimaging and concurrent psychedelic use will be reviewed in order to further understand the neuroplasticity and altered consciousness that the brain undertakes. Review of these studies will be used to discuss potential current treatment options not being utilized and implications for new pharmacological therapies.

Neutrophil-Lymphocyte Ratio as an Inflammation Marker in a Case With Neuroleptic Malignant Syndrome

Poster Presenter: Nesrin Karamustafalioglu
Co-Authors: Tevfik Kalelioglu, Guler Celikel

SUMMARY:

Introduction: Neuroleptic malignant syndrome (NMS) is a rare and life-threatening side effect of antipsychotic treatment. The core symptoms of NMS are hyperthermia, rigidity, autonomic instability, and altered mental status after initiation of antipsychotic medication (1). In this case report we aimed to discuss the role of inflammation in NMS and usefulness of neutrophil to lymphocyte ratio (NLR) as

an inflammatory marker even in the absence of leukocytosis. Case: A 30-years-old woman with a 17 years history of bipolar affective disorder was transferred to acute care psychiatry service with acute exacerbation. She was treated with haloperidol 20 mg/day i.m, biperiden 10 mg/day i.m. On the 7th day of hospitalization the patient developed rigidity, tremor and incontinence without fever. Thus haloperidol was stopped for probability of NMS. 8th day of admission ECT was initiated. At 11th and 12th day of hospitalization, haloperidol i.m. was used for acute excitations. Rigidity, confusion, diaphoresis, tremor, tachycardia, and incontinence occurred at the following day. Her temperature was 36.3, heart rate was 110 per minute, respiratory rate was 15-20 per minute, blood pressure fluctuated between 90/70 and 110/70 mm/hg and oxygen saturation was 97%. Laboratory findings revealed increased levels of CPK(>2000 IU/L; normal range= 20-200), AST (188 U/L; normal range= 5-45), ALT (66 U/L, normal range= 5-40), LDH (581 IU/L; normal range=60-200), CRP (1.84 mg/dl; normal range= 0-0,5), erythrocyte sedimentation rate (ESR) (44 mm/hour; normal range= 0-20). Leukocyte count (6.35 103/µL; normal range= 4.1-11.2) was in normal range. At 19th day, confusional state developed and by the day of 20, bromocriptin 5mg/day was initiated with the diagnosis of NMS using the criteria of DSM-5. On the 29th day of admission, all symptoms of NMS disappeared. Antipsychotic treatment initiated with clozapine 12,5 mg/day because of excitation. The patient developed rigidity as cogwheel sign, dystonia, altered mental status, autonomic dysregulation after 6 days of clozapine initiation and interned to intensive care unit at 37th day of admission. After 6 day of hospitalization in intensive care unit, she was transferred back to psychiatry service. On 43th day, bromocriptine was increased up to 10 mg/day for presence of rigidity and dystonia. By the day of 57, no symptoms of NMS was observed. Discussion: In our case; NLR level was above 9 at the time of NMS diagnosis before initiation of NMS treatment. We did not observe fever and leukocytosis during hospitalization. Although leukocyte levels were in normal range, NLR levels were nearly as higher as a systemic infection level. In addition, the NMS development after starting clozapine showed a NLR level of >5 which is between the cut-off level of local infection levels (2). In our case we observed a relevance between NMS treatment and NLR levels. (shown in Table)

No. 131

Pareidolia in a Patient With Major Depressive Disorder: A Case Report

Poster Presenter: Olaniyi O. Olayinka, M.D., M.P.H.
Co-Authors: Olawale Ojo, M.D., Chiedozie Obinna Ojimba, M.D., M.P.H., Tolulope A. Olupona, M.D., Ayodeji Jolayemi, M.D.

SUMMARY:
Introduction: Pareidolia is defined as a type of complex visual illusion that involves the perception of ambiguous forms as meaningful objects. It is a peculiar, natural, function of the human brain that causes us to impose patterns on random collections of images or sounds. The ability to recognize faces is a function of the Fusiform Face Area (FFA) located in the fusiform gyrus of the temporal lobe of the human brain. Pareidolic illusions have been reported in Lewy Body Dementia and Parkinson disease but rarely in Major Depressive Disorder (MDD) as in the index case. MDD affects approximately 7% of the population and may be associated with perceptual disturbances (i.e., illusions and hallucinations). The presence of visual perception disturbances pose a treatment dilemma and often portend a worse outcome in mental disorders and neurocognitive disease. Case Summary: We describe the case of a 63-year-old Hispanic woman who presented to the emergency room for evaluation for a persistently depressed mood. She presented with an agitated and disorganized behavior as a result of seeing “the ugly looking” devil. She stated that the images were present while she was awake as well as in her dreams. She endorses perceptual disturbances of seeing the faces of evil spirits trying to talk to her and engage her. She had only minimal interactions with peers on the unit and showed a low drive and motivation and a downcast appearance. Patient has a past history of postpartum depression with a suicide attempt and a past medical history of pseudo-seizures. The patient was treated with Buspirone 10mg PO tid, with a favorable response in her mood and resolution of her illusions. Discussion: This case is an example of complex visual illusions in the context of a major depressive episode which resolved with the initiation of an antidepressant.

Consideration for temporal lobe seizure was made however numerous neurological examinations prior to presentation make the diagnosis of seizures very unlikely.

No. 132

Is the Kynurenine Pathway a Bridge Between Serotonergic and Glutamatergic Systems in the Schizoaffective Spectrum?

Poster Presenter: Paulo Marcelo Gondim Sales, M.D.
Co-Authors: Ezra Schrage, Richard Coico, Michele Tortora Pato, M.D.

SUMMARY:

Introduction: The Kynurenine Pathway (KP) is responsible for up to 95% of the tryptophan degradation in humans(1), and a recent meta-analysis suggests that both bipolar disorder and schizophrenia share differences on levels of KP metabolites when compared to healthy controls(2). Despite evidence suggesting the influence of neuroinflammatory pathways in the pathogenesis of schizoaffective spectrum disorders and biological evidence that cytokine levels directly influence levels of KP metabolites, only a limited number of studies investigated susceptibility genes involved in the dialogue between the KP and inflammation. Methods: A critical review was conducted on MEDLINE, EMBASE, Cochrane, and PsycINFO to identify genetic studies that investigated the kynurenine pathway in schizoaffective spectrum disorders. Results: In 2006, Aoyama et al published the first single-marker and haplotype analyses for 6-tag Single-Nucleotide Polymorphisms (SNP) of the Kynurenine Monooxygenase (KMO) in an association study with schizophrenia(3). However, despite evidence confirming the reduction of the KMO gene expression and KMO enzyme activity in a postmortem study of schizophrenia patients(4), the findings were not replicated using a second independent set of samples of Japanese ancestry(3). In 2009, investigating SNPs located in six genes in a predominantly Caucasian population, an increased odds ratio for the combined diagnosis of schizophrenia and bipolar disorder was found in carriers of the complex genotype HM74, which was observed in 30% of the cases(5). The authors proposed that this may derive from co-regulation of the kynurenine pathway by interacting genes or alterations in the metabolism of melanotropin receptor ligands through the KP metabolism. Also, during another genotypical investigation of 15 KMO SNPs in a predominantly Scandinavian population, no difference in the allele frequency between patients and healthy controls(6), similarly to what was found by Aoyama et al. The first genome-wide association study investigating KP metabolites was only published in 2016(7), in a study that found an association between elevated cerebrospinal fluid levels of kynurenic acid with positive psychotic symptoms and executive function deficits in bipolar disorder with a common variant within 1p21.3, which was lastly linked with reduced SNX7 expression. Table 1: outlines the common markers and different populations, reviewed by these core studies and show where their results supported and refuted each other. Discussion: Altogether, there is a paucity of studies that investigated the genetic determinants that regulate the cross-talk between KP and inflammation. Tryptophan catabolites might be responsible for driving neuroplastic changes through 5-HT and glutamate in schizoaffective spectrum disorders. Further studies are necessary to clarify the roles of kynurenine pathway susceptibility genes for the phenotypical manifestation of schizoaffective spectrum disorders.

No. 133

Periodic Catatonia Marked by Hypercortisolemia and Exacerbated by the Menses

Poster Presenter: Samantha Zwiebel, M.D., M.A.

SUMMARY:

Introduction: Since catatonia was first introduced by Kahlbaum in 1874, other psychiatrists including Kraepelin have observed patients with a periodic, recurrent catatonia. Gjessing, a Norwegian psychiatrist dedicated his life to study the biological abnormalities of patients with periodic catatonia. Leonhard, a German psychiatrist proposed that periodic catatonia was a specific subtype of familial schizophrenia. Case description: The grandmother (mother of her father) of this patient died in a psychiatric hospital probably due to a catatonic episode. At the time of admission to a long-term psychiatric unit in a state hospital, the patient was 40-year-old female who was followed for more than 4 years in which she had 4 episodes of catatonia that

were exacerbated by the menses. Results: On the first day that the senior author saw the patient with catatonic symptoms, he misdiagnosed her with overwhelming anxiety of unknown cause and treated her with oral lorazepam. During the catatonic episodes, she had elevations in serum creatine kinase (CK) and hypercortisolemia with pronounced leukocytosis. Her CK values peaked as high as 4,920 U/L during times of severe agitation and during the second catatonic episode that lasted 13 months, CK elevations were accompanied with elevations on the serum lactate dehydrogenase (LDH) up to 424 U/L. She had hypercortisolemia with late-afternoon values as high as 28.0 mcg/dL. Her white blood cell (WBC) counts went up to 24,200/mm3 accompanied by neutrophilia without any infection. Before coming to the state hospital she had 16 prior psychiatric admissions in private hospitals. The psychiatrists at these hospitals for the most part did not appear to be familiar with the diagnosis of catatonia but described elevations on WBC and LDH and an abnormal response to dexamethasone suppression test (DST) that normalized with electroconvulsive therapy (ECT). Discussion: We proposed that 1) the serum CK and LDH elevations reflect the severity of muscle damage incurred during her catatonic episodes, 2) her leukocytosis with neutrophilia was probably explained by demargination of neutrophils into active circulation by hypercorstisolemia, and 3) the hypercortisolemia may be compatible with the abundant literature of the relevance of fear in catatonia. This case is discussed in the context of a comprehensive review of the literature on 1) menstrual exacerbations of catatonia, 2) biological abnormalities on periodic catatonia and 3) familial periodic catatonia as a possible separated diagnostic entity. Conclusion: This patient exhibited a possible familial form of periodic catatonia that worsened when her menses and was accompanied with hypercortisolemia during the catatonic exacerbations.

No. 134
Encephalitis in Autism
Poster Presenter: Shweta Jain
Co-Author: Shahbaz A. Khan, M.D.

SUMMARY:

Autism was discovered in 1943 by Leo Kanner who believed it to be caused by the emotional unavailability of the child's mother. There is a growing body of literature that demonstrates an inflammatory etiology of autism. Evidence of inflammation in autism spectrum disorder (ASD) includes microglial activation and elevated anti-NMDA receptor antibodies, particularly in regressive autism. There is research suggesting that up to 69% of ASD patients have microglial activation and neuroinflammation. Variation in the pathogenesis of autism with both neuroinflammatory and psychosocial models calls for the use of differentiated therapy such as intravenous immunoglobulins and steroids in the former, and conventional symptomatic treatment for the latter. The objective of this translational literature review is to create a decision tree that incorporates the neuroinflammatory model and illustrates a more differentiated workup and management to mitigate ASD symptoms in certain patients.

No. 135
Exercise in Psychiatry Schizophrenia: Effect of Exercise on Negative and Cognitive Symptoms
Poster Presenter: Zeshawn Ali, D.O.
Co-Author: Rashi Aggarwal, M.D.

SUMMARY:
Often medications target the positive symptoms of schizophrenia but have very little effects on the negative symptoms as demonstrated by current literature. Exercise is an inexpensive treatment method that is not fully harnessed in the treatment of patients in private and organized settings. We will review how the benefits of exercise can apply to improving the negative symptoms and quality of life in patients with schizophrenia by reviewing evidence for effect on contributing conditions (depression and anxiety) and its direct impact on cognition and negative symptoms. Method: Literature review was done on PubMed and Google search by using the keywords "exercise", "schizophrenia", "depression", "anxiety", "cognition", "brain." Results: Numerous articles were reviewed for the purposes of this literature review. 8 studies were reviewed in detail with respect to to aerobic exercise and positive impact on cognition and brain plasticity in general. In schizophrenic patients (atrophy demonstrated in

areas of the brain) one study in particular demonstrated plasticity in the hippocampus of schizophrenic patients with increase in size and some associated functional relevance in cognitive domains. With respect to anxiety and depression the studies to be referenced are 4. The main study with respect to depression is an extensive meta-analysis published in 2016 that demonstrates a large antidepressant effect (aerobic exercise), when compared to controls, establishing it as a clear evidence based treatment for depression. The studies of interest with respect to anxiety show significant effect of mild to moderate exercise on anxiety likely via exposure therapy (mimicking physiological state), affecting negative memory, and building self efficacy. 10 studies were were reviewed in detail demonstrating evidence that aerobic exercise improved performance in cognitive domains in schizophrenics along with improvement in global functioning and depression in one meta-analysis. Overall there was significant improvement noted in domains such as negative symptoms, social cognition, working memory, attention, and processing speed. Discussion :The evidence for aerobic exercise improving negative symptoms in schizophrenia is fairly solid. There is heterogeneity in some studies with respect to what the exercise entails. Interestingly so, as noted in some, the complexity of the exercise can open new doors in treatment settings with respect to treating negative symptoms, encouraging complex social interaction and identity formation. Studies are already present with respect to schizophrenia showing impairments in object affordance and sensory integration, everything that more complex exercise can help with. Studies that are more specific in the types of exercise and take into account cognitive theories should be undertaken to further elucidate the effect this can have. This can perhaps give rise to clear specific evidence which fuels funding for more integrative programs.

No. 136

Metabolic Disturbances and Psychosis Case Report: Hypercapnia Secondary to Tracheal Stenosis Exacerbating Psychosis

Poster Presenter: Zeshawn Ali, D.O.
Co-Authors: Juvaria Anjum, Ghulam Sajjad Khan, M.B.B.S., Najeeb U. Hussain, M.D.

SUMMARY:
A 57-year-old female patient with a past history of paranoid schizophrenia and asthma presented with disorganized behavior, auditory hallucinations and was internally preoccupied and superficially cooperative. Physical examination was significant for stridor (inspiratory and expiratory) and scar tissue on the anterior aspect of the neck secondary to tracheotomy. The underlying story behind the tracheotomy was unclear (given patient's disorganization). Patient's lab, oxygen saturation was within normal range, she was medically cleared, and it was assumed that stridors were due to the scar tissue. Aripiprazole was started but the patient was noted to be more psychotic, paranoid, disorganized and withdrawn. Hence it was crosstitrated with Olanzapine. Depakote and Gabapentin were also added. Patient's affect, mood and judgment improved. However, psychotic symptoms seemed to remain stable. While on the Psychiatric inpatient unit, stridor persisted and worsened;eventually she had wheezing and troubled breathing (with drop in O2 saturation)for which she was started on nebulizer treatments (had been seen by medicine). Despite adequate consultation and care she collapsed on the unit and was transferred to medicine and subsequently the surgical unit secondary to hypercapnic respiratory failure and treated for her respiratory acidosis. She became stable but could not speak (tracheotomy) and expressed herself in writing. She was on same medications and dosages of antipsychotics. The patient was far more linear in her writing (had written before in a very disorganized fashion) and denied auditory and visual hallucinations, stating she felt better in that aspect specifically, while writing she no longer saw the shadows or heard voices for the first time in her nearly month stay. This was just a week removed from her inpatient psychiatric stay, and complicated medical hospitalization. In this poster, we demonstrate how metabolic conditions like "subclinical" respiratory acidosis affect the central nervous system and potentially exacerbate psychiatric conditions despite not being evident in the classical sense, and how this can potentially confound treatment of a patient.

No. 137

"Doctor, Is My Brain Wired With Excess Copper?": A Case of Neuropsychiatric Symptoms in Untreated Chronic Idiopathic Copper Toxicity

Poster Presenter: Merry Mengyuan Huang
Co-Author: Ozra Eslampanah Nobari, M.D.

SUMMARY:
Introduction: Copper is a highly reactive metallic ion [1]. The highest concentrations of copper in the human body is located in the liver and brain [2]. Copper is an important cofactor for enzymes involved in neurotransmitter synthesis and collagen production. However, its excess causes oxidative damage and tissue deposition leads to global organ impairment [3]. Copper excess is commonly recognized interchangeably as Wilson's disease, however, isolated chronic copper toxicity can be an organic cause to psychiatric disturbances. Case: The patient is a morbidly obese wheelchair-bound 43 years old Caucasian female with dysphonia in the form of distinct child-like intonation and a complex medical and psychiatric history. She presented to the Emergency Department (ED) by police due to Suicidal Ideation (SI) and behavioral disturbances and considering the patient's extensive history of over 33 psychiatric hospitalizations, she was admitted to inpatient care. During the course of her hospitalization, the patient was initially agitated and combative. After minor medication adjustment, her mood improved and anger outbursts decreased, however, her long-standing passive SI remained unchanged. Clozapine and lithium were not tried to target her suicidality due to past failed trials [4]. Patient's hospitalization prolonged due to complicated post discharge placement, which allowed the primary team to revisit the diagnosis and investigate the underlying cause of her clinical presentation. Her past medical history was significant for a wide range of diagnoses including osteoarthritis, seizure disorder, Obstructive Sleep Apnea, recurrent Deep Vein Thrombosis, chronic pain, dermatitis, nonspecific thyroid disorder, anemia, endometriosis, numerous gastrointestinal problems, and status post bariatric surgery with multiple revisions. Chart review for psychiatric history revealed the diagnosis of developmental delay and intellectual disability at a young age as well as series of emotional, physical, and sexual abuses. Patient experienced a new onset of seizures, migraines, and hallucinations at her 20s and was placed on SSDI for her disabilities. The rest of the psychiatric history was inconsistent and puzzling. In this poster, we present a case of a 43 years old female with significant medical and psychiatric history. We explore the role of idiopathic copper toxicity at explaining this patient's diverse clinical symptoms. Discussion: Micronutrients imbalance cause psychiatric disturbances. Chronic idiopathic copper toxicity is suggested to be considered as an organic cause of unexplainable neuropsychiatric symptoms especially in the setting of other seemingly unrelated medical problems. Medications used to treat excess copper is extremely inexpensive compared to the costs of inpatient hospitalizations. We suggest that detection of copper toxicity and early intervention can improve patient care outcomes.

No. 138

"How Many Warning Signs Did I Miss to End Up in the Psychiatric Unit, Doctor!": The Mysterious Case of Trauma Related Catatonia

Poster Presenter: Ozra Eslampanah Nobari, M.D.

SUMMARY:
Case Report: A 40-year-old female with a psychiatric history for multiple episodes of untreated depression was brought to the emergency department by her friend for incoherent speech, isolative and odd behaviors and passive suicidal statements in the past year which had intensified in the last two months. Reportedly, the patient was not able to care for self and was found the day prior to admission wandering in her neighborhood, walking in circles. The friend explained that the patient was highly educated and successful professional for years. At the time of admission, she appeared to be anxious and oriented to place and person only. Her speech was incoherent, tangential and pseudo-philosophical in nature. She was unable to answer basic questions regarding her emotions, seemed to be paranoid, demonstrated odd movements and appeared to be responding to internal stimuli. Her vitals also were suggestive of dysautonomia. Patient's medical history was only significant for recent primary care physician visits over the past few months due to worsening abdominal discomfort and fever, without any etiology identified. Upon

admission, a full medical workup, including first episode psychosis work up and OB-GYN and neurology consults were unrevealing. Formal assessment of catatonia revealed grimacing, mannerisms, rigidity, negativism, withdrawal, impulsivity, mutism and Mitgehen (with a score of 20 on the Bush-Francis rating scale). Benzodiazepine challenge test improved the patient's symptoms. She was initially diagnosed with Major Depressive Disorder (MDD) with psychotic features and catatonia. She responded well to benzodiazepine treatment. During hospitalization and as the patient started to improve, she was able to report the loss of a close relative two months prior to admission. Her daily conversation with the team was remarkable for symbolism and religious meaning in life which in combination with catatonia symptoms were indicative of her progress. When the symptoms of acute catatonia improved, the team discussed starting antipsychotic medications. She consistently declined medications to treat her mental illness because taking medications was contradictory to her belief system including the primacy of therapy. However, after she finally agreed to try antipsychotic medications, optimal improvement observed. Later in hospitalization, the etiology of her catatonia and mood symptoms was not fully understood. A psychology consult revealed the history of trauma following depressive episodes, highlighting an unreported suicidal attempt which was not fully executed due to the patient's decreased cognitive function. The patient explained the incident of trauma which took place two years ago and the amnesia to the events around the time of incident due to the head injury. She acknowledged that her mental condition declined severely and steadily right after the incident. She was discharged with the additional diagnosis of Post Traumatic Stress Disorder on ari

A Case of Visual Hallucinations Following Basal Ganglia Stroke

Poster Presenter: Saad Ahmed, M.D.
Co-Authors: Shahed Hossain, Ayodeji Jolayemi, M.D.

SUMMARY:

Introduction: The etiology of visual hallucinations in elderly usually involves lesions to subcortical structures,including basal ganglia, as can be seen in Lewy body dementia.These basal ganglia lesions are degenerative in nature. We report a case,where the patient presented with similar to presentation of Lewy body dementia. However, clinical presentation along with radiological studies suggested that visual hallucinations in this patient might have been a result of basal ganglia stroke. Case Summary: We present a case of an elderly male who was brought to the psychiatric ER for visual hallucinations and no obvious cause and was initially suspected for Lewy Body Dementia.However,the absence of key criteria evidenced by the patient's generally intact cognition and motor system in conjunction with his favorable response to antipsychotics largely preclude its likelihood.Suspect diagnosis also sharing features with patient's presentation include peduncular hallucinosis,seizure activity and Charles Bonnet Syndrome but the patient's timing of his experiences unrelated to sleep wake cycles,imaging studies not implicating the thalamus,midbrain and brainstem,that he displayed no other characteristic features of seizures including lack of altered sensorium or postictal elements and that he was not visually impaired render them unlikely.Charles Bonnet Syndrome was further challenged by the patient's fearful emotion demonstrating lack of insight and preserved visual integrity,despite the history of cataracts and glaucoma.Patient ambulated without visual aid and his neural circuitry was therefore not deprived of the visual input which could have then otherwise incited inhibitory release thereby sparking hallucinations.Another diagnosis of interest was inspired by the patient's past medical history of HTN and DM,mild cognitive decline and supporting MMSE/MoCA scores which are suggestive of psychosis secondary to vascular dementia.It is especially a viable candidate in light of its status as the second most common cause of neurocognitive decline,after Alzheimer's disease. His intact motor functioning,gait and his preserved urinary continence however once again suggests alternative explanations.The most conspicuous element inspiring deeper investigations was a lacunar infarct seen on brain MRI which the literature revealed to be a known and rare cause of psychosis and hallucinations.The phenomenon is partially explained by the interplay between prefrontal cortex and subcortical structures though

reports have also surfaced detailing hallucinations post lesions in a wide variety of neuroanatomical structures. Conclusion: Further studies to consider include a clarification as to what agents may promote perceptual disturbances in stroke patients versus agents that disrupt said factor as well as the anticipated onset of psychosis post CVA. Long term surveillance of treated patient may also be of utility.

No. 140

"Shaky Pain": A Case of Beta Blocker Non Responsive Akathisia

Poster Presenter: Saad Ahmed, M.D.
Co-Authors: Olaniyi O. Olayinka, M.D., M.P.H., Tolulope A. Olupona, M.D., Ayodeji Jolayemi, M.D.

SUMMARY:
Introduction: Akathisia is the one of the most common forms of Extrapyramidal Symptoms (EPS) resulting from the use of neuroleptics. It usually presents as motor restlessness with a compelling urge to move and an inability to sit still. When akathisia is present, our first intervention is a cautious reduction in antipsychotic dose, if feasible, with close monitoring of the patient for exacerbation of psychotic symptoms. If decreasing the antipsychotic drug dose is not feasible or inadequate, medication treatment is suggested. One of the most commonly prescribed medication used for treatment for neuroleptic induced akathisia is beta-blocker, most commonly Propranolol. Case summary: Here we report a case akathisia in a middle-aged female with Schizophrenia who failed to respond to beta blocker. Patient received Propranolol in the past without any improvement of her symptoms, rather her symptoms worsened. Patient continued to exhibit symptoms of akathisia and complained of "shaky pain". Benztropine was introduced to the regimen at a low dose, up-titration of Benztropine initially seemed to help with the symptom of akathisia, but patient continued to complaint of "shaky pain", which was observed to be related to anxiety associated with akathisia. Subsequently Clonazepam was introduced with expectation of reducing anxiety related to akathisia, but symptoms did not subside and was subsequently discontinued. Trihexphenydyl was introduced which provided symptomatic relief and proved to be most effective of the medications attempted to date for this patient. Discussion: Although akathisia is one of the most common EPS presentations, its management beyond beta blockers remain unclear. This case examines the possibility of using a commonly overlooked medication in treatment of akathisia. Conclusion: As side effects are the most common causes of noncompliance with medications and therefore relapse, management of side effects need to be robust. This is especially true for side effects with poorly understood pathophysiology which can complicate treatment choices. In cases where conventional treatment fails to provide adequate response, trial of less commonly used medications may provide better response. Further studies are encouraged to focus on currently available pharmacotherapeutic agents that could possibly be used to treatment and prevention of side effects.

No. 141

Ulysses Syndrome: Immigrant Syndrome of Chronic and Multiple Stress

Poster Presenter: Gonçalo Sobreira
Co-Authors: Cátia Alves Moreira, João Oliveira

SUMMARY:
Introduction The eponym Ulysses Syndrome, coined by Spanish Psychiatrist Joséba Achotegui, was first used in 2002 to describe a condition afflicting migrants(1). These populations, who might have already experienced enormous stressor levels (often near lethal migratory journeys), are then later exposed to adaptation stressors like different languages, isolation, lack of work opportunities, diminished social status or a sense of failure and are thus at risk of developing this syndrome, a severe psychosomatic disorder leading to Adjustment Disorders(2). Methods Case report and narrative literature review of the PubMed database about Immigrant Syndrome. Case report The authors report the case of a 33-year-old, Sub-Saharan African Woman, residing in a Portuguese refugee centre since 2015. The patient came to Portugal searching for refugee status due to political conflicts in her home country. She was first electively admitted in June 2016 to an Interventional Neuroradiology Unit for treatment of multiple aneurisms, found after third cranial pair paresis investigation. The intervention resulted in retroperitoneal hematoma,

hypovolemic shock and parietal-occipital stroke. During the next two months, she had multiple ER visits due to orbitofrontal headaches. However, after careful evaluation organic causality was discarded and she was then referred, in late December, to psychiatric treatment at a Refugee Treatment Group due to Adjustment Disorder with Depressive Symptoms (DSM5 – ICD10 F43.21). Nevertheless, she was then voluntarily admitted (March 2017) to a Psychiatric Unit, after referral by her case manager to the ER due to depressive mood, irritability, aggressive behaviour, disorganised speech, persecutory delusions, and inversion of sleep pattern, with the diagnostic hypothesis of Psychotic Disorder due to another medical condition with delusions (DSM 5 – ICD10 F06.2). During her admission, she was evaluated by Liaison Neurology and Internal Medicine and organic causality was again discarded. Several symptoms of the PTSD spectrum were present but full criteria were not met (no criterion C) and the previously considered delusional thoughts were later evaluated by transcultural psychiatry and deemed adequate considering her cultural background. She attained provisional response after 37 days (HAMILTON scores improvement from 7 to 1) and was discharged after 44 days with the diagnosis of Depressive episode with insufficient features (DSM5 ICD10 – F32.8). Conclusion Even though Ulysses Syndrome is not a consensual entity the stressors faced by migrant population in their welcoming countries might lead to the development of Adjustment Disorders which might result in severe functional loss. Strategies should be put in place in order to improve mental health and quality of life of these populations.

Sociodemographic Characterization and Analysis of Clinical Effectiveness of Utilizing rTMS for Refractory Depression at a Military Treatment Facility
Poster Presenter: Michael Sieun Yang, D.O.

SUMMARY:
Background: The mechanism of action for the efficacy of TMS is still debated but stimulation of neurogenesis via BDNF production is a popular theory. This study evaluated whether rTMS treatments resulted in a measurable and statistically significant improvement in depression symptoms for treated military beneficiaries in Hawaii suffering from depression. It also examined rTMS utilization rates by branch of service, active duty status, and other demographic factors. **Objective:** This study seeks to evaluate whether rTMS treatments resulted in a measurable and statistically significant improvement in depression symptoms for treated military beneficiaries in Hawaii suffering from depression. It also examines rTMS utilization rates by branch of service, active duty status, and other demographic factors. **Methods:** A retrospective chart review of 77 rTMS patients who received and completed treatment between January 1, 2010 and October 31, 2016 was performed. Under a typical treatment regime, patients receive rTMS for six weeks, totaling 31 treatments, as well as weekly psychiatric assessments, which included completion of Beck's Depression Inventory (BDI) and Posttraumatic Stress Disorder Checklist (PCL). Data extracted included patient gender, race and ethnicity, age, status and branch of service if applicable, primary and secondary diagnosis, history of antidepressant treatment to include number of medications prescribed and length of time taken, and pretreatment and post-treatment testing scores for BDI and PCL. A mixed model repeated measures analysis was done assuming an autoregressive order one covariance structure to evaluate changes over time. Adjusted analyses were done to assess whether changes over time differed by age, prior diagnosis of PTSD, active duty status, and gender. **Results:** The majority of patients were from the Army (74%) and 56% were active duty servicemembers. Just over half (53%) were male. BDI and PCL scores were significantly lower at end of treatment on average compared to the pretreatment baseline scores. Mean differences for BDI and PCL were significant with $p<0.001$ at 1–15, 16–30, and 31–45 days after TMS treatment was initiated. Overall, 44% of patients experienced a reduction of 10 points or more on BDI, and 38%

experienced a reduction of 10 points or more on PCL. **Conclusion:** Our research found that rTMS treatments produced a significant reduction in symptoms of depression and PTSD in patients at this treatment facility. Broader implementation of this treatment modality may prove beneficial for the purposes of military readiness, given current policies and restrictions on servicemembers who are initiated on antidepressant medications. These results may also provide further support for the use of rTMS to treat non-depressive disorders such as PTSD and bipolar disorder.

No. 145

ADHD and TMS: Efficacy and the Emergence of Biomarkers; a Review

Poster Presenter: Pranav Milind Jagtap, M.D.

SUMMARY:

Introduction: ADHD is characterized by inattention, impulsivity, and hyperactivity. These symptoms are present in a variety of psychiatric illnesses such as bipolar disorder, Tourette's and tic disorders, anxiety, psychosis, substance use, and more; but because evaluations are subjective, the condition can be misdiagnosed and consequently mistreated. Daily TMS of the left prefrontal cortex (PFC) is FDA approved for treatment resistant depression and its mechanism of action is hypothesized to alter dysfunctional neuro-circuitry. However, the utility of this novel therapy in other psychiatric disorders remains to be determined. Since most psychiatric disorders are characterized by cognitive executive dysfunction, we took a closer look at TMS and its effects on attention deficits. Methods: Pubmed was surveyed for literature using the terms: ("Attention Deficit Disorder with Hyperactivity"[Mesh]) AND ("Transcranial Magnetic Stimulation"[Mesh] OR transcranial magnetic stimulation); filters were: 10 years, Humans, English. The results were further manually sorted by both authors to identify literature reviews, meta-analyses, and randomized/sham controlled trials (RCTs) pertaining to ADHD. Findings from these studies were summarized to provide a broad overview of the current applications of TMS for ADHD. Results: The initial search results returned 119 entries matching the query; and of these four were RCTs, 27 were literature reviews, and there were two meta-analyses. One cross-over double blind RCT (3) demonstrated improvements in attention immediately following high frequency rTMS to right dorsolateral PFC. Wu et al (8) delivered a proof-of-concept for fMRI navigated rTMS by stimulating the supplemental motor area to elicit hemodynamic changes in the motor cortex. Two RCTs (1,4) corroborated reliable changes in the TMS evoked potential N100, as a marker of motor cortical inhibition and correlated it clinically with symptomatic improvement. Several trials also favored the utility of short interval intra-cortical inhibition (SICI) as a biomarker for inhibitory cortical circuitry in ADHD and related disorders. Conclusion: These findings provide encouragement for the community as we inch closer towards the era of precision psychiatry (2). TMS can be applied focally to improve attention deficits by reconfiguring activity in dysfunctional networks; and given that PFC connectivity within attention networks is sensitive to the slightest of changes in stimuli (5), it is unsurprising to see even a single session of rTMS induce clinical improvement. SICI and TMS-N100 potential were replicated in various studies to substantiate clinical utility as objective proxies for hyperactivity and motor cortical inhibition in ADHD and related conditions. The relatively side-effect free profile of TMS is an attractive feature while patients will likely appreciate generalizable cognitive benefits across many domains and co-morbid afflictions (6,7).

Is ECT + Ketamine 1/∝ Catatonia?

Poster Presenter: Raissa Elaine Lavin Tanqueco, M.D.
Co-Author: Gretchenjan Lactao

SUMMARY:

Ketamine has been hailed as the must try medication in treatment resistant depression. There is limited literature regarding ECT with use of ketamine as anesthesia for catatonia (most recent was Z Litvan, 2017 in a case of depression and dementia in a geriatric patient). In this poster, we explore a case of a much younger patient and review the highs, lows, and lessons learned. Mr. K is a single, domiciled, unemployed young adult Asian male with past psychiatric history of major depressive disorder with psychotic features, poor adherence to treatment, and was brought in to the

emergency department by family members due to concerns of Mr. K's refusal to eat for several days. On exam he appeared to be catatonic, with prominent features of negativism, mutism, and posturing. Mr. K's lack of engagement, poor self care, and failure to thrive progressed during hospitalization and resulted in >30 lb weight loss in two months. He intermittently accepted lorazepam and fluoxetine. Curiously, Mr. K eventually signed to voluntarily receive ECT. However, no notable improvement was evident after multiple rounds of ECT. A trial of ketamine as anesthetic was used for subsequent ECT treatments. Upon returning to the unit following the first dose of ketamine received during ECT, Mr. K appeared to be more cooperative with care, nutrition, and medications. Ketamine was used for an additional four times during ECT. Mr. K progressed to be more motivated, less isolative, no longer requiring prompting with meals or medications, joining group therapies, responding appropriately to questions, and speaking spontaneously at times. After nearly three months in the hospital, Mr. K requested to be discharged home. His family felt comfortable with this plan, and he was scheduled to continue ECT twice a week on an outpatient basis with outpatient psychiatric follow-up. How do you think our protagonist fared?

No. 147

Response to Preexisting Paruresis Along With Major Depression and Generalized Anxiety Disorder Treated With Electroconvulsive Therapy (ECT)

Poster Presenter: Rassam Khan, M.D.
Co-Author: Ye-Ming J. Sun, M.D.

SUMMARY:
Background/objective: Paruresis manifests in a fear and inability to urinate in public restrooms when other persons are present. Paruresis can create significant social, interpersonal, and occupational distress. Individuals with paruresis are at noted risk for both major depressive disorder and generalized anxiety disorder. About 50% of individuals with paruresis have at least one other comorbid diagnosis. From most to least common, comorbid diagnoses include social anxiety disorder, major depressive disorder, alcohol use disorder, and obsessive-compulsive disorder. Case Report: A 24-year-old Egyptian American male, single, unemployed, living with parents complains of "I can't urinate when I am away from home and even at home when I hear foot steps". Patient has the history of paruresis since age 8. However, in the past several months the patient has worsened. He has poor self-esteem, troubled sleeping, feeling helpless and hopeless. He has passive suicidal ideation but no active suicidal or homicidal ideations. He also reported excessive anxiety and worrying over many things not necessary for many years. These symptoms have worsened to the point they are interfering with his social and professional activities. Patient has exhausted all his options from therapy to different cocktails of medications; none seemed to improve his symptoms. Patient uses alcohol and cannabis occasionally. There is no known family history of psychiatric illness. At the time of initial evaluation patient was already on Clonazepam 1mg q12 hr, risperidol 0.25mg bid, venlaxfaxine 75mg daily, hydroxyzine 50mg bid. After ECT, patient stated he is now able to initiate urination when not at home. Also noticed improvement in symptoms of depression and anxiety. Method/Results: ECT was administered with a MECTA Spectrum 5000Q unit. Average seizure length was 42.2 seconds measured by EMG and 70.1 seconds measured by EEG. The patient was followed with Hamilton Depression rating scale (HAM-D), Yale Brown Obsessive Compulsive Scale (YB-OCS), and Social Phobia Inventory (SPIN), and Beck's Anxiety. The baseline scores consisted of HAM-D score 20, SPIN 48 (severe), Beck's 29 (moderate), YB-OCS 38 (severe), MMSE 30/30. After ECT there was improvement with the following scores of 11, 28, 18, 23, 30/30 respectively. Discussion: Treatments currently available to patients suffering from paruresis are limited (Soifer, Zgourides, Pickering, 2001). While cognitive behavioral therapy shows consistent efficacy in managing symptoms of paruresis (Soifer&Walsh, 2008). Pharmacological intervention has generally proven "disappointing" in the treatment of paruresis (Bohn and Sternbech, 1997). Our hope is that this report will add further discussion about the possible usage of ECT in similar cases where paruresis with comorbid diagnosis of major depression and anxiety can show improvement in the patient's symptoms overall.

No. 148

A Case of Periorbital Erythematous Plaques Possibly Induced by Electroconvulsive Therapy

Poster Presenter: Sarita Sharma, M.D.
Co-Authors: Vinod N. Alluri, M.D., Nana K. Cudjoe, M.D., Maggie Armstrong

SUMMARY:
Background: Psychiatrists use electroconvulsive therapy (ECT) to treat a variety of psychiatric conditions. Contrary to popular belief, ECT is safe (Tess and Smetana, 2009). ECT has several well-known, though often benign side effects, which notably do not include rash (Tess and Smetana, 2009). The most common somatic complaints of ECT are headache, disorientation and memory deficits. Side effects do not change early or late in the ECT course and are not influenced by ECT electrode placement or dosage (Devanand, et al., 1995). Clinicians may have difficulty finding the etiology for adverse dermatologic reactions to ECT, and though such reactions are infrequent, they can be quite distressing for patients. There is little, if any, literature to date that demonstrates adverse dermatologic reactions directly related to ECT (Gomez, 1975). Case Presentation: A 55-year-old woman presented for inpatient ECT following the recommendation of her psychiatrist for treatment of severe, recurrent major depression without psychotic features. After medical clearance, the patient underwent her first bilateral ECT treatment. The next day, the patient developed new bilateral, periorbital erythematous plaques which were neither painful nor pruritic. She denied the use of new soaps or lotions and denied self-injury; antinuclear antibody (ANA) and Erythrocyte Sedimentation Rate (ESR) were within normal limits. Three days following treatment, her rash appeared to be resolving and the decision to continue with a second ECT treatment was made. For the next several treatments, her rash would wax and wane with the timing of ECT; her bilateral, periorbital plaques would flare in intensity within 24 hours following ECT and diminish between treatments, though never fully resolving. After discontinuing the use of all soaps and lotions, intramuscular diphenhydramine, topical hydrocortisone 1%, and changing sedative medications from Methohexital to Propofol failed to affect the dermatologic course, the decision was made to change from bilateral to unilateral ECT. Following right-sided unilateral ECT treatment, the right-sided unilateral, periorbital erythematous plaques flared while the left-sided periorbital rash resolved. Conclusion: Possible etiologies of the patient's dermatologic condition included new soaps and lotions, which the patient denied, and medication reaction, including anesthesia, which would typically present as a diffuse reaction. The patient's localized, relapsing and remitting rash seems unlikely to have resulted from a new topical treatment or medication We hypothesize that the ECT treatment itself is what precipitated the unique rash-like presentation in the patient. A possible explanation includes an underlying dermatologic condition that was previously unknown to the patient and exacerbated by the electrical current. This dermatologic reaction may be a result of ECT and could be distressing to patients, though such reaction would be both rare and benign.

No. 149

The Effectiveness of Combined Etomidate and Ketamine in Electroconvulsive Therapy (ECT) for Optimal Treatment in Major Depressive Disorder

Poster Presenter: Tolu Oyetunde
Co-Authors: Rassam Khan, M.D., Ye-Ming J. Sun, M.D.

SUMMARY:
Background: The effectiveness of an Electroconvulsive therapy (ECT) session is determined by a multitude of factors, one of which is seizure quality and duration. Our aim is to compare the duration of seizures using different anesthetics. An optimal seizure duration lasts about one minute. Our aim was to determine whether etomidate and ketamine combination would produce longer seizure duration. In addition ketamine alone has been used effectively treating Major Depressive Disorder. Thus, the combination of etomidate and ketamine would boost the effectiveness in ECT treating treatment-resistant Depression. Case: Mr. L is a 55 year-old Caucasian male, with a psychiatric history of Major depressive disorder severe w/o psychotic features and generalized anxiety disorder. He was on sertraline 200mg, quetiapine 200mg Qhs and vistaril 100mg tid. These medications were not helping his symptoms and he continued to present with flat

affect, poor sleep, anhedonia, helplessness, hopelessness and suicidal ideation without plan. No homicidal ideations or hallucinations. He has a previous history of alcohol abuse but quit 2 years ago. Initially his mini mental status exam was 30/30 and Ham-D was 21. Due to treatment-resistant depression, he was started on ECT treatment. Method/Results: ECT was administered with a MECTA Spectrum 5000Q unit (MECTA Corporation, Portland, Oregon). Standard unilateral-right electrode placement was used, with seizure activity monitored. Patient was started with methohexital (140mg) and seizure duration was inadequate even with 500mC maximum charge. Then the patient was given ketamine (70mg) and methohexital (70mg) with a mean charge delivered at 499.9mC in which his seizure lasted 23 seconds by EMG and 25 seconds by EEG. In order to produce more effective seizure duration, the patient was given Etomidate (15mg) and Ketamine (70 mg). For this treatment first mean charge delivered 224.5mC and subsequent stimulation was 325.1 mC. The first mean charge produced seizure duration of 19 seconds measured by EMG and 29 seconds measured by EEG. Subsequent stimulation measured 25 seconds by EMG and 44 Seconds by EEG. Succinylcholine i.v. was used for muscle relaxation. Conclusion: Our results indicate that the combination of etomidate and ketamine is the best combination than ketamine and methohexital or methohexital alone in optimizing seizure duration as well as depression improvement.

No. 150

Clozapine and Aripiprazole for Borderline Personality Disorder With Multiple Suicide Attempts: A Case Report

Poster Presenter: Felix Oscar Priamo Matos, M.D.
Co-Authors: Darmant Bhullar, M.D., Panagiota Korenis, M.D., Daniel Romulus Roman, M.D.

SUMMARY:
Borderline personality disorder (BPD) is a pervasive pattern of instability of interpersonal relationships, self-image and affects, with marked impulsivity, beginning by early adulthood and present in a variety of contexts (1). Pharmacotherapy with antipsychotics, antidepressants and mood stabilizers has been used to control brief psychotic episodes, depressed and labile mood, and impulsivity (2). This is a 34 year-old female with a psychiatric history of BPD, schizoaffective disorder, post-traumatic stress disorder, multiple hospitalizations and suicide attempts, and multiple episodes of sexual abuse, with a medical history of seizure disorder, polycystic ovary syndrome, hypothyroidism, asthma, obstructive sleep apnea and obesity who was admitted to the inpatient psychiatric unit due to suicidal ideation and command auditory hallucinations. During the initial evaluation, Ms. K reported command auditory hallucinations of unrecognizable voices of both genders encouraging self-injurious behavior. The patient also reported passive suicidal ideation without a plan and vivid dreams about the previous episodes of sexual abuse. She was successfully treated with Clozapine titrated to 600 mg oral (200 every morning, 400 at bedtime), Aripiprazole Maintena 400 mg intramuscularly monthly, Sertraline titrated to 100 mg oral daily, Prazosin 5 mg oral at bedtime, and Oxcarbazepine 900 mg every morning and at bedtime for a period of sixty one days. During the inpatient course, she constantly reported suicidal ideation with a plan of slashing her wrists and jumping from a chair, and responded to command auditory hallucinations encouraging her to bang her head against the wall, leading to multiple restraints and seclusions. This behavior led to the patient being placed on constant visual observation and receiving multiple intramuscular injections, and as needed medications to control the above self-injurious behaviors. A significant and sudden improvement was noticed in self-injurious behavior and psychotic symptoms with the above regimen during the last week of hospitalization, in contrast to previous case reports where the patients improved clinically within 2 weeks, on average, with 400 mg or less of clozapine, without receiving other antipsychotics or augmentation with Oxcarbazepine (3). More importantly, the delayed response to therapy could be due to her multiple medical comorbidities, as well as psychiatric history of schizoaffective disorder and post-traumatic stress disorder could explain the difference in her hospital course compared to other BPD patients.

No. 151

Tintin, the Secret Identity: A Study Behind Tintin's Personality Traits

Poster Presenter: Jaime Valero
Co-Author: Juan Cano, M.D., M.Sc.

SUMMARY:
Personality has been defined from different perspectives, a variety of scales has been used in order to measure the numerous personality traits. Scales that gave little guidance with poor concept-name relation with some of these traits and also that varies according to each assessor's scale interpretation. In order to fight against this problematic, an integration of concepts with the introduction of a descriptive model in personality psychology was the solution to it. An extenuating researched that involved along the years several variables in order to determine five dimensions had to be made to structure the taxonomy in human personality. These variables rated from people with no more than high school education to first year graduate students, ratings by peers, supervisors, teachers, or experienced clinicians in diverse settings. The analyses, made at the time by Tupes and Christal found five strong and recurrent factors between descriptions. This five-factor structure was later replicated by Norman, Borgatta (1963), Goldberg in the 1981 named them "Big five" to emphasize the amplitude of each factor (1). The Adventures of Tintin (Les Aventures de Tintin) a series of 24 comic albums that were created by a Belgian cartoonist George Remi who wrote under the pseudonym of Herg'. He created a personage that became one of the most popular European comic characters of the 20th century. It is developed during a pretty realistic era. It was written in more than 70 languages around the world, with sold over to 200 million copies. This case is then a study of Tintin's personality traits, a man in his early twenties. Tintin is a clever journalist and adventurer/pilot. Also, a man with a particular endurance who has survived collisions and crashes, capable of fight to bring two men by himself, fight corruption without too much effort. He has excellent people skills and speaks a bunch of languages which is very helpful in connect to different humans, let`s not forget that he also loves animals, for example his loyal partner Snowy ("Milou" in French). So, we have a person who has a very good reputation if we ask captain Haddock (his adventure companion), and has no bad habits and apparently is one of the best humans in the comic world. However, to the question how can such a wonderful human being can be alone? The interest to know some of his personality traits could showed some psychopathology or the fact that he is just gay, some facts are that he never showed interest in girls, a dog that is unambiguously heterosexual having the tendency to be distracted by lady dogs, tendency that is blocked by his owner, what about his best friend, a middle-aged sailor? Really? So, the writer might want to keep him in the closet all these years (2).

No. 152
Use of Electroconvulsive Therapy in Patients With Major Depression and a Comorbid Borderline Personality Disorder
Poster Presenter: James Hyun Lee

SUMMARY:
Background: Previous research suggests that electroconvulsive therapy (ECT), a gold standard in the treatment for severe unipolar depression, is not as effective when the patient presents with a comorbid borderline personality disorder (BPD). To test this claim, ECT outcomes of patients with and without BPD were compared in a retrospective chart review. Methods: The study consisted of 137 patients with a diagnosis of unipolar major depression who completed the McLean Screening Instrument for Borderline Personality Disorder (MSI-BPD). 29 met criteria for BPD. The difference in PHQ-9 scores before and after ECT was compared between the BPD and non-BPD groups. Data about rehospitalizations and follow-up PHQ-9 scores post-treatment were collected and analyzed. Results: ECT markedly improved symptoms of depression in both patients with borderline personality disorder and those without the disorder (Mean PHQ-9 score pre-ECT = 20.42; Mean PHQ-9 score post-ECT = 7.24; $p < .001$). There was no difference in PHQ-9 score differences between the BPD (Mean difference = 14.38) and non-BPD groups (Mean difference = 12.84, $p = .851$). After ECT treatment, both groups underwent a characteristic increase in PHQ-9 score. There was no difference in the degree of PHQ-9 increases between the two groups over the following six months after receiving treatment ($p = .763$). Conclusions: Unlikely prior research, these

data show that patients with and without BPD respond equally well to ECT, and the rates of symptom recurrence post-ECT and rehospitalization were not significantly different between the two groups. These findings may reflect that clinicians in our institution have learned to avoid ECT in the treatment of chronic misery in BPD but still use the treatment for severe neurovegetative depressions in patients with and without BPD. Consideration of ECT in these cases of BPD may be warranted.

No. 153

Psychological Attributes and Psychosocial Barriers to Prevention of Recurrent Self-Inflicted Burns

Poster Presenter: Joshua Ryan Smith, M.D.

SUMMARY:

We report the case of a 31 year old Caucasian male who has repeatedly presented to our institution for self-harm by chemical burn using sodium hydroxide (Oven Cleaner) and who has required multiple surgical interventions over a five year period. This case report was done in conjunction with the plastic surgery department. In this vein, we discuss self-inflicted burns from both a surgical and psychiatric perspective. From a surgical standpoint the mortality, specifics of injury, and need for psychiatric co-management of cases similar to this are explored. Additionally, the difficulty with diagnostic nosology of recurrent self-inflicted injury is discussed along with challenges in obtaining stable outpatient psychiatric follow up in rural communities. This is done by investigating the specifics of funding for community service boards in Virginia. Lastly, given that this patient demonstrates features of Borderline Personality Disorder, the need for widespread application of generalist practices to meet psychotherapeutic needs of patients with similar presentations is discussed. This is a novel case report given that the topics of interdisciplinary care, diagnostic nosology, approach to generalist psychotherapeutic practices, and treatment availability are able to be discussed.

No. 154

The Reemergence of Borderline Personality Disorder Symptomatology in an Older Patient

Poster Presenter: Michael Frederic Weil Dreyfuss
Co-Authors: Andre Burey, M.D., Ross E. Goldberg, M.D., Julie B. Penzner, M.D.

SUMMARY:

Borderline personality disorder (BPD) symptomatology is typically seen to diminish with age, including decreased impulsivity, self-injurious behavior and suicidality. However, features of affective instability, unstable interpersonal relationships and identity disturbance may be more persistent across the lifespan of individuals with BPD. We present the case of a 69-year-old patient with BPD who presented with depressive symptoms and affective lability in the setting of multiple life stressors and recent retirement. Her presentation occurred following a period of relatively stable symptomatic dormancy during middle life while she was employed. Her example illustrates that patients may be susceptible to a resurgence of BPD symptoms in the setting of later life stressors and biological maturation, suggesting an enduring core psychopathology of BPD that is environmentally sensitive. BPD in later life is relatively less well studied. This case highlights the importance of understanding the course of BPD into later years, and examining which individual and environmental factors predict sustained remission.

No. 155

The Psychiatric Management of Adults With Intellectual Disability and Comorbid Borderline Personality Disorder: Is Medication Helpful?

Poster Presenter: Rupal Ekeberg
Co-Author: Richard John Hillier, Ph.D., MB.Ch.B.

SUMMARY:

Borderline personality disorder (BPD) is characterized by pervasive instability of emotions, interpersonal relationships, self-image, and behaviour. It has received increased clinical attention and has been more widely researched compared to other personality disorders, perhaps due to the nature of its presentation and associated risks and morbidity. It is present in approximately 1% of the population and has a lifetime prevalence of around 6% though rates in the intellectual disability (ID) population are not well understood or reported. We know that there is a higher prevalence in woman, perhaps because they are more likely to present to services for help. The numbers of people

with BPD are likely to be underestimated in the ID population as positive behavioural support plans are widely used to manage challenging behaviour1. Thus the challenging behaviour of BPD is often managed using positive behavioural support without the official diagnosis of personality disorder ever being given. There are a number of people at the mild end of the ID spectrum who do present more classically with mood instability, suicidal ideation and repeated deliberate self harm, often complicated by alcohol and substance misuse. These people have often been started on different medications for their depressive or anxiety symptoms, often with the working diagnosis of anxiety and depression. As occurs in the mainstream, these people often become embedded to a model of perceiving their hope in finding the "right" tablet that will resolve all of their symptoms. In the UK, there is currently no drug that has the marketing authorisation for the treatment of borderline personality disorder but in clinical practice, medications are often used to help manage comorbid mood symptoms and crisis situations2. Moreover, there is little evidence to support of the effectiveness of medications in BPD with few randomised controlled trials of interventions and further research necessary. In this poster we looked at adults with ID and an established diagnosis of BPD across two community services in London. We discuss how successful we have been in supporting these people to re-evaluate their treatment options and move away from the model of looking for the "perfect pill". We look at the role of psychotropic medication within the multidisciplinary management plan and effectiveness of medication on their clinical presentation.

Treatment-Refractory Self-Injury by Starvation in an Adolescent Male With Borderline Personality Disorder

Poster Presenter: Brooke R. Mastroianni, M.D.

SUMMARY:

Borderline Personality Disorder is defined by DSM-5 as a pathological personality resulting in significant inability to function both personally and in society. Criteria of a borderline personality disorder include poorly developed self-identity, chronic feelings of emptiness, inability to set and pursue goals, disturbances in interpersonal functioning including decreased ability to empathize with others, emotional lability, frequent anxiety, depressed mood, fear of abandonment, and self-harm behavior. Self-harm behaviors most often are in the form of cutting, although this can encompass any self-injurious behavior. This case is of a 16-year old male with borderline personality disorder whose primary method of self-harm is self-starvation. This case is atypical due to the patient's presentation, co-morbid psychiatric conditions, and resistance to treatment. The most prominent co-morbid psychiatric symptomatology complicating treatment is severe obsessive-compulsive thoughts and behaviors, thus far refractory to treatment. The initial trigger for his self-harm behaviors and obsessive-compulsive tendencies was looking at pornography at 14-years-old and feeling extreme guilt afterwards. His guilt persisted and he felt the need to "punish" himself. This, along with emotional instability, disturbance in self-image, splitting, many episodes of self-harm by cutting and scratching, and ultimate self-harm by starvation brought his diagnosis of borderline personality disorder to light. There has been a significant debate regarding primary and subsequent diagnoses, understandably so as this is an incredibly complex case that has not responded to any treatment modality to date. The patient has persisted with food restriction, suicidal ideation, self-harm behavior, and mood instability through a variety of psychiatric facilities. His unique presentation, non-response to a variety of psychiatric treatments, and diagnostic complexity are discussed in this poster for a comprehensive look at this atypical case of self-starvation.

Reviewing the Cluster A Personality Disorders Through the Music and Composition of Billy Joel

Poster Presenter: Shawen Maryrose Ilaria, M.D.
Co-Author: Anthony Tobia

SUMMARY:

We aim to review the Cluster A Personality Disorders, including Paranoid Personality Disorder, Schizoid Personality Disorder, and Schizotypal Personality Disorder through the music and composition of Billy Joel. We review the etiology and

clinical characteristics of these Personality Disorders through multiple works of the singer and songwriter including Pressure, Sometimes a Fantasy, and You May Be Right. To our knowledge, this is the first pedagogic analysis of personality disorders through music.

Factors Associated With Improvements in Real-World Functioning in an Early Stage of Schizophrenia: A One-Year Follow-Up Study

Poster Presenter: Leticia Gonzalez-Blanco
Co-Authors: Maria Paz Garcia-Portilla, Leticia Garcia-Alvarez, Lorena de la Fuente Tomás, Pilar A. Sáiz, Celso A. Iglesias, Julia Rodriguez-Revuelta, Angela Velasco, Julio Bobes, M.D., Ph.D.

SUMMARY:
Background: Negative, cognitive and depressive symptoms, as well as physical comorbidities, have a great impact on the real-world functioning in patients with schizophrenia (SZ) (1,2,3). However, not all the studies have considered all these factors simultaneously nor have been analyzed in longitudinal studies. The objective was to determine if clinical or biological factors at baseline could predict improvements in the functionality of SZ at 1-year follow up. Methods: Prospective study of 57 stable outpatients with SZ (less than 10 years of illness) [mean age= 31.5±6.5; 63.2% males]. Clinical variables: PANSS, CGI-Severity, Clinical Assessment Interview of Negative Symptoms (CAINS) - Motivation/Pleasure (MAP) & Expression (EXP) domains-, Brief Negative Symptom Scale (BNSS), Calgary Depression Scale (CDS), MATRICS Consensus Cognitive Battery (MCCB), PSP. Biological variables: Glucose, cholesterol, LDL, HDL, triglycerides, TSH, prolactin, insulin, uric acid, alkaline phosphatase (APh), C-reactive protein (CRP), TNF-α, interleukin(IL)-6, IL-2, IL-1β, IL-1RA, homocysteine, HT (% hemolysis), lipid peroxidation (LPO), catalase. Pearson correlations and multiple linear regression analyses were performed to identify variables significantly related to changes in PSP scores at follow-up [PSP follow-up score − PSP baseline score]. Age, sex, education, and other potential confounding factors were considered. No significant changes in BMI, waist circumference, smoking or antipsychotic equivalent doses at follow-up were detected, but they were also considered in regression analyses. Results: At follow-up PSP average score did not significantly change from baseline (56.3±19.9 vs. 54.5±18.3; t= -1.397). Final regression model for improvements in PSP total score at follow-up (R2=0.312, F=5.605, p=0.003) identified that speed of processing T-scores of MCCB (β= 0.337), % hemolysis (β= 0.310) and homocysteine levels (β= 0.310) were significant predictors. Discussion: Increased levels of oxidative stress biomarkers and better cognitive performance at baseline, specifically the speed of processing domain, predict better outcomes of real-world functioning at 1-year in an early stage of SZ.

No. 159

Computer-Delivered Cognitive Behavior Therapy as Care Augmentation for Depressed Primary Care Patients

Poster Presenter: Arthur Secundino Leitzke, M.D.
Co-Author: Roderick R. Stuart, M.D.

SUMMARY:
Background: The 12-month and lifetime prevalence rates of Major Depressive Disorder in the US are 6.6% and 16.2%, respectively . Depressed individuals are most frequently treated in the primary care setting . Cognitive behavior therapy has been shown to have efficacy similar to antidepressant medication for Major Depressive Disorder and to be at least as efficacious as other psychotherapies . Computerized Cognitive Behavioral Therapy (cCBT) offers an avenue for addressing the demand and cost of CBT and providing its benefits in primary care , .. To date there have been no published studies that determine the financial benefit to a health plan of offering cCBT to its adult primary care population. Our randomized controlled study evaluated the efficacy of depression treatment augmentation with cCBT in primary care patients. Methods: The study setting was Kaiser Permanente's Family Medicine Clinic in Fontana, CA. Adult patients newly diagnosed with depression were emailed or mailed an invitation to participate, and were asked to visit a recruitment website where they completed a questionnaire to assess eligibility (PHQ-9 score ?5). Eligible patients who provided informed consent were randomized to intervention or treatment as usual. Participants in the treatment arm were were

emailed a code to access a computerized 8 week Cognitive Behavioral Therapy program (Thrive - Waypoint Health Innovations). The primary outcome was PHQ-9 scores. These scores were measured at baseline and 2 and 6 months follow-up, Preliminary data from the 2 month follow-up are reported . Results: 297 patients were randomized, of whom 180 (60%) completed the two month follow up and were analyzed. Participants mean age was 47.2, and19% were male. Baseline PHQ-9 scores for for theintervention and control group were not significantly different (mean=14.32 vs. mean=14.75p=0.9473). At 2 months follow-up, the PHQ-9 score was significantly different between the intervention and control groups (mean=8.531 vs. mean=11, P=0.0098). Endpoint subgroup analysis of the PHQ-9 score between control and treatment groups showed significance only for those patients with initial score between 5-9 (P=0.0168) (Mean – Control=6.8, SD=3.489; Treatment=4.0, SD=3.024) and 10-14 (P=0.0494) (Mean – Control=9.516, SD=4.106; Treatment=7.259, SD=4.736). Patients with initial PHQ-9 score of 15-19 (P=0.5719) and 20-27 (P=0.6132) did not show significant difference between control and treatment groups. Conclusion: In adult patients diagnosed with depression in primary care, the addition of a 8 week computerized CBT program reduced depressive symptoms among patients with mild to moderate symptoms.

No. 160

Starting a New Psychodynamic Psychotherapy Resident Teaching Clinic: Wellness for Patients, Residents, and Supervisors

Poster Presenter: Kathleen K. Burns, M.D.
Co-Authors: Jacqueline A. Hobbs, M.D., Gary Lawrence Kanter, M.D.

SUMMARY:
ACGME requires that residents have significant experience evaluating and treating individual psychotherapy patients longitudinally for at least one year, along with demonstrating competence in psychodynamic psychotherapy. Psychodynamic psychotherapy clinic was created to allow residents protected time for education, development and utilization of learned skills, and to receive supervision from attendings to improve competency and quality of care. It all started when a psychiatrist with 35 years of private practice experience as a psychodynamic psychotherapist decided to come back to academics. His dream was to develop a psychodynamic psychotherapy training clinic for residents. One year later after his feet were firmly planted in the academic world, the training director reminded him of his dream then told him to make it happen. Twelve residents participating in their PGY-3 yearlong longitudinal outpatient experience were divided into two groups. Each group was assigned to either a Tuesday or Thursday 4-6 PM psychodynamic psychotherapy clinic. The structure included two 50-minute patient sessions and group supervision with two attendings and other residents in the same clinic between and after the sessions. Attendings used a structured supervision covering major themes, goals of therapy, identified affects, appropriate patient selection, etc. The goal of group supervision is to assist the resident in preparing for individual supervision, which occurs for 2 hours at additional times during the week. Prior to the first scheduled patient, there was a 1-month weekly seminar during the same 4-6 PM time to prepare residents for the beginning of psychotherapy clinic. Supervisors interviewed patients through a one-way mirror to allow residents to see how an initial psychodynamic psychotherapy interview is performed and how it is different from the typical new patient evaluation. Other teaching techniques included the use of the HBO series In Treatment to discuss psychodynamic themes. Results to date are that residents have learned the importance of being present and connected with the patient. They are learning to truly listen, follow the patient's "agenda" and not their own, and maintain appropriate boundaries. They are also learning the intricacies of supervision. Ultimately, via the psychodynamic psychotherapy clinic, the residents are getting back to a true focus on their patients that will hopefully contribute to improving their overall satisfaction with the training experience and enhancing their wellbeing. Faculty supervisors are rediscovering the joy of teaching through observing the weekly growth of the budding psychodynamic psychotherapists.

No. 161

Improvement of Patient Follow-Up in the UT Health SA Psychiatry Resident Psychotherapy Clinic

Poster Presenter: Kavita Demla

Co-Author: Adrian Paolo Agapito, M.D.

SUMMARY:
Background: Psychotherapy has been shown to improve patient outcomes in many mental health conditions when compared to treatment with medications alone and can also be effective monotherapy in some cases. Training in psychotherapy is therefore an important element of education for psychiatrists. Psychiatry residents at the University of Texas Health San Antonio have an ongoing therapy training experience at the ADVANCE clinic. However, many patients entering the ADVANCE clinic do not follow up after their initial evaluation, which impedes patient care, resulting in poorer outcomes, and leads to deficiencies in resident education. This study aims to increase the number of completed follow-up psychotherapy appointments by 50% during a two-month period. Methods: baseline data were extracted from the electronic medical record to review number of follow-up appointments attended over a two-month period. These patients were surveyed to determine barriers to psychotherapy attendance. At the start of intervention, psychoeducation regarding commitment for maximal therapeutic response was provided in both verbal and written format via discussion of goals and expectations and providing a flyer to the patient, respectively. Additionally, multiple follow up appointments were scheduled after the initial evaluation. Results: findings from the survey of barriers to attending follow-up appointments demonstrated the following in order of highest to lowest mode of responses: patient being too busy, change of insurance, patient disliking therapy, limited provider availability, patient disliking therapist, provider-initiated, patient preferring medication management only, and transportation issues. Results of percent of residents with more than three follow up appointments over a two-month period of intervention were averaged to be 30%, which is not statistically significant when compared to results from before the intervention. Conclusion: our aim was not successfully achieved thus far from preliminary results, however data from subsequent two-month cycles of intervention will continue to be collected. We also aim to collect baseline and subsequent Hamilton Anxiety rating scales in order to trend another possible component of improvement with this intervention. If results continue to be statistically insignificant, we will reevaluate and address other variables in barriers to follow-up. This includes expanding scheduling options by considering a weekend or evening clinic and creating a task force to explore and assess therapist variables to improve patient-therapist fit. Aiming to increase therapy follow-up will contribute to improvement in patient symptoms, resident education and competency, and support of clinic revenue to allow for continued ability to address the mission of education.

Decoding Psychotic Images Through Art Psychotherapy and Exploration of Potential Application of Virtual Reality
Poster Presenter: Mani Yavi, M.D.

SUMMARY:
The application of art psychotherapy allows exploration of psychotic mental states and can assist in recreation of disconnected mental images. Through the empathetic guidance of the therapist and artistic self-expression, where the logical expression and the pressure of time are minimised, patients are able to express deep affective and idiosyncratic material. Pictures created in art therapy can be valuable windows to the intrinsic mental states of the schizophrenic patient. In this report we present and detail the application of art therapy on the inpatient setting, in particular focusing on cases with schizophrenia, to transform anxious, psychotic mental imagery to forms that are psychologically more adaptive and reality-oriented. Lastly we will review the literature on advances in the field of Virtual Reality and discuss the potential of this emerging technology to augment treatment modalities.

No. 163
Is It Possible to Experience the Nature of Psychotherapy in One Session for the Medical Students?
Poster Presenter: Yong Chon Park, M.D.
Co-Authors: Yubin Cho, Mirim Yun, Seokmin Noh

SUMMARY:
Receiving psychotherapy is one of the best ways of

training for psychotherapy, along with supervision and the literature review. However the medical students in Korea learn psychotherapy in the classroom and the contents are limited to introducing theories of psychotherapy. For over twenty years, the author found that touching the emotion is the most influential impact to the medical students, for most of them have alexithymia tendency. The only chance for medical students to experience psychotherapy is during the rotational clerkship. Therefore, the author tried to develop the way of experiencing psychotherapy for medical students in one session.

No. 164

Clozapine-Induced Symptomatic Hepatotoxicity

Poster Presenter: Stephanie Sutton, M.D.
Co-Author: Sriram Ramaswamy, M.D.

SUMMARY:

We present a case of symptomatic clozapine-induced hepatotoxicity in a 48-year-old Asian American female at the VA Hospital. The patient was started on clozapine for treatment-resistant Schizophrenia after failing multiple antipsychotic trials including dual antipsychotic therapy. She initially tolerated the medication well and experienced a significant improvement of symptoms including auditory hallucinations. She was followed weekly in the VA clozapine clinic. About six weeks after the initiation of clozapine, the patient presented to the clinic with malaise, fatigue, and abdominal pain. After evaluation by the psychiatrist and the primary care physician including obtaining lab work, it was determined that the patient had developed clozapine-induced hepatotoxicity. The medication was discontinued due to her side effects including rising LFTs. Most psychiatrists focus on the risk of agranulocytosis in patients on clozapine requiring CBC with differential, however it is also important to monitor other labs early on during the initiation process including CMP. Some elevation of LFTs during clozapine treatment can be asymptomatic and transient, however there have been cases of fulminant hepatic failure in the literature (1). Deciding whether or not to re-challenge clozapine after elevated transaminases is a decision the provider needs to make. While there are not many cases of clozapine-induced symptomatic hepatotoxicity in the literature, a surprising number of the reported cases are found in female patients ranging from ages 39-50 (2). Multiple patients had Asian background such as our patient. We will explore if female gender or Asian ethnicity puts a patient at risk of clozapine-induced hepatic adverse effects. While clozapine can be an extremely effective medication for patients who suffer from treatment-resistant Schizophrenia, Schizoaffective Disorder, and Bipolar Disorder, it requires close monitoring due to serious side effects that can lead to morbidity and and even mortality.

No. 165

Wellbutrin-Induced Dystonia: A Case Report and Review of Literature

Poster Presenter: Vikas Gupta, M.D., M.P.H.
Co-Authors: Roopma Wadhwa, M.D., M.H.A., Marsal Sanches, M.D., Ph.D.

SUMMARY:

Case: Ms. A., a 28-year-old Caucasian female with a past psychiatric history of major depressive disorder, ADHD and alcohol use disorder, presented to psychiatric outpatient clinic with worsening jaw clenching since the past month. She has complaints of neck and jaw stiffness and feels she has been more fidgety lately. Patient notes that jaw clenching and difficulty with head rotation is making it very difficult for her to function. She has tried physical therapy and used dental guard to protect her teeth. Patient has also maintained sobriety from alcohol for the past 2 months. Prior to coming for this visit, Ms. A. was being prescribed 20mg fluoxetine, 40mg lisdexamfetamine dimesylate (Vyvanse) and 450mg bupropion XL. Bupropion XL was started 8 weeks ago with dose augmentation in the past month. Reduction of the bupropion dosage to 300mg XL once daily improved the symptoms in 3 days and further reduction to 150mg daily totally resolved the symptoms after 2 days of dose reduction TO 150mg.
Discussion: Medication-induced focal dystonias may present with dramatic head and neck muscle spasm with occasional jaw clenching, bruxism, and TMJ syndrome. In this case, the jaw clenching and neck stiffness resolved partly with dose reduction in 3 days and ameliorated completely on further reduction of dose of the offending agent.
Conclusion: This case suggests that some patients

may experience dose-related acute dystonic adverse reactions to bupropion. Dystonias have been linked to acute dopamine depletion and basal ganglion-derived gamma synchronization dysfunction. This is more commonly seen in antipsychotics. However, bupropion also has been implicated in reports of medication-induced dystonia.

No. 166

Aripiprazole and Gambling Disorder: A Qualitative Review of Literature

Poster Presenter: Yam Giri

SUMMARY:

Background: Aripiprazole (ARI), a second-generation atypical antipsychotic, is among one of the commonly prescribed psychotropic medication. Food and Drug Administration (FDA) has approved it for the treatment of schizophrenia, an acute manic episode of bipolar disorder, as an adjunct for both major depressive disorder and maintenance phase of bipolar disorder, and autism-related irritability. ARI-related gambling disorder (GD) has been increasingly reported in the literature, mostly from Australia and Europe, and it causes psychological distress, financial losses, and social consequences. It is believed to cause GD due to the hyperdopaminergic state in the meso-limbic pathway as a result of its agonist properties in dopamine-3 (D3) receptors and partial agonist action in D2 receptors. Methods: To gain deeper insights of this growing concern, we conducted the literature search in PubMed/Medline, Google Scholar, relevant websites, and textbooks, and reviewed the published articles. We included three case reports, five case series encompassing 18 cases, one case-control study, and other review articles that were published in the English language. Results: We identified 21 published cases of GD associated with ARI included in three case reports, five case series. Majority of subjects were male (number of cases, n=20) and remained one was female. The average age of the subjects was 34.7 years. Majority of patients received oral ARI 15 mg/day (n=9), followed by 20 mg/day (n=6), 10mg/day (n=4) and 5mg/day (n=2). Out of 21 cases, 12 cases were found to have increased in prior gambling behavior after ARI treatment, whereas remaining nine subjects developed new onset GD. The onset of gambling after ARI initiation was few months (n=11), few weeks (n=4), few years (n=3), and few days (n=1). ARI discontinuation resulted in complete resolution of GD in the majority of cases (n=17) and decreased in gambling in one case whereas in two subjects GD was resolved with specialized care and psychotherapy without stopping ARI. Reducing the ARI dosage resulted in the reduction in gambling in remaining one case. In the majority of cases, GD resolved or decreased in severity in few weeks (n=9) to few months (n=7). Conclusion: All prescribers should be aware of the association of ARI and GD and patient should be assessed for the increased risk of GD before starting ARI especially with the prior history of impulse control disorders and gambling behavior. Close monitoring of such behavior, early identification, and appropriate treatment can help prevent the harmful consequences of GD.

No. 167

Severe Nephrolithiasis and Hyperammonemia Associated With Topiramate: Case Reports and Review of the Literature

Poster Presenter: Zhong Ye, M.D.

Co-Authors: Louis W. Solomon, M.D., Jacqueline A. Hobbs, M.D.

SUMMARY:

Topiramate is a pharmacologic agent approved for seizure treatment and migraine prophylaxis but is also recognized in the psychiatric community as an off-label agent for bipolar disorder, substance use disorders, bulimia nervosa, binge eating, PTSD and neuropathic pain. Its diverse usage is attributed to its wide range of CNS effects such as GABA agonism as well as antagonism of voltage-gated sodium channels, L-type voltage-activated calcium channels, carbonic anhydrase isozymes and AMPA/kainite receptors. Thus, topiramate's most noted side effects are fatigue, dizziness, memory impairment, paresthesia, coordination problems and visual deficits – all attributed to topiramate's direct effects on the CNS. Less talked about are the metabolic effects. The discussion of topiramate-induced metabolic side effects rarely spans beyond anorexia and weight loss. This poster presents two cases that address two less known metabolic effects – topiramate-induced nephrolithiasis and topiramate-induced hyperammonemic encephalopathy. In the

former, a 57-year-old female patient with bipolar disorder and PTSD was admitted to the psychiatric hospital for treatment of severe depression. Topiramate was initiated due to the patient's complaint of severe migraine headaches exacerbating her depression. Within 6 weeks, she developed severe flank pain, fever, vomiting, low urine output, and hematuria. Imaging revealed a left 7-mm obstructing stone and bilateral nephrolithiasis. Though the patient had a history of nephrolithiasis and a stent placement over 25 years ago, the timing of such a severe exacerbation after so many years may indicate a role of topiramate that is known to contribute to nephrolithiasis. In the latter case, a 56-year-old female with a history of bipolar disorder, PTSD and seizures was admitted for suicidal ideations in a major depressive episode. She was restarted on her self-reported home medications, one of which was topiramate 100mg TID for seizure disorder. She started becoming more confused and by day 5, she was obtunded and transferred to the emergency room. Her ammonia level was 155. She was promptly treated with lactulose, and topiramate was discontinued. Her ammonia levels trended down, and she recovered quickly. She later stated she was not sure if she had actually been taking topiramate at home. Neurology was consulted and concluded that this was a case of topiramate-induced hyperammonemia. Both cases above resulted in severe patient compromise that resolved after topiramate was discontinued. The mechanisms behind these adverse reactions are not entirely understood, but the top hypothesis for both stem from topiramate's inhibition of carbonic anhydrase. Given topiramate's frequent and ever-expanding off-label use, psychiatrists should be aware of these possible adverse effects. This awareness should prompt careful consideration of past medical history prior to prescribing topiramate as well as proper monitoring and preventative measures.

No. 168

The Black Box Warning of Cymbalta - Fact or Fiction?

Poster Presenter: Hanan Khairalla, M.D.
Co-Author: Vandana Doda

SUMMARY:
The FDA warns about the increased risk of suicidal thoughts and behavior in patients who are prescribed antidepressants, particularly children, adolescents and young adults. Short-term studies did not show an increase in the risk of suicidality with antidepressants compared with placebo in adults older than 24 years. In this case report, we discuss a case of a 29 year old patient with history of depression and chronic bilateral lower extremity pain who presented to the Emergency Room with new onset suicidal thoughts after an increase in the dose of Cymbalta from 60 mg daily to 90 mg daily. The patient had been on Cymbalta for 3 months prior to the emergence of the suicidal thoughts. He was subsequently hospitalized and treated with gabapentin, venlafaxine, melatonin and hydroxyzine. Within 24 hours, the suicidal thoughts dissipated and the depressive symptoms had improved. This case indicates that Cymbalta can increase the risk of suicide in individuals older than 24 years of age and that the risk is also present with higher dosages. Overall, Cymbalta is a safe medication but physicians should closely monitor all patients, irrespective of age during the first three months of treatment.

No. 169

Near Suicide Attempt in a 17-Year-Old With Pseudo-REM Sleep Behavior Disorder Associated With Undiagnosed Obstructive Sleep Apnea: A Case Report

Poster Presenter: Hanan Khairalla, M.D.
Co-Authors: Lancer Naghdeci, Nicole A. Guanci, M.D.

SUMMARY:
The importance of evaluating sleep quality in adolescents is tantamount. In this case report, we discuss a 17-year-old female with a history of major depressive disorder, recurrent, in partial remission and pseudo-REM Sleep Behavior Disorder (RBD) secondary to undiagnosed obstructive sleep apnea (OSA) who was found attempting to hang herself with no knowledge or recollection of the event in the absence of an acute mood episode. After not responding to her mother's calls, she was found in a "daze" standing in her underwear on a chair with a belt tied in a noose with scotch-tape and hung on a "toy string" on the ceiling. She was confused upon questioning by her mother and stated that was not aware of what she was doing – an apparent suicide attempt that was ego-dystonic to her. She

subsequently returned to baseline with no further incidences since. On evaluation three days later, the patient reported that she was dreaming about a friend who committed suicide by overdose when the patient was in sixth grade. The patient recalled that in the dream, she was extending her hand to try to reach out to her friend when she heard her mother calling her, causing her to awaken to finding herself standing on top of the chair with no recollection of how she got there. The patient reported history of misplaced objects in her room with no recollection of moving them. Her mother reported finding drawings of corpses on the wall while patient was sleeping once when she was in sixth grade. The patient admitted having issues with sleep duration and being unable to fall back asleep. Her mother denied recent changes in patient's baseline mood (described as "somber" and chronically depressed at 5/10), recent changes in behavior, and neurovegetative symptoms. The patient admitted that she often thinks about death but denied suicidal thoughts since one year prior, homicidal thoughts, manic, hypomanic or psychotic symptoms. Her family history included a sibling with autism and a father with parkinson's and dementia. On examination, the patient's vital signs were stable and mental status exam was within normal limits with the exception of a constricted affect. The patient was worked up for seizure disorder versus REM sleep disorder. The EEG study ruled out seizure disorders. However, the overnight polysomnography study showed findings consistent with a diagnosis of obstructive sleep apnea. Patient was thus diagnosed with OSA and Pseudo-RBD. This case highlights the importance of sleep studies and diagnostic clarification in adolescents presenting with stable mood symptoms and inconsistent behaviors related to disrupted sleep.

No. 170

A Case of Valproic Acid-Induced Hyperammonemic Encephalopathy Complicating Dementia

Poster Presenter: Yara Moustafa, M.D., Ph.D.
Co-Authors: Ivonne Torriente Crespo, M.D., Alican Dalkilic, M.D.

SUMMARY:
Valproic acid has been used in the treatment of epilepsy, bipolar and schizoaffective disorder, dementia-related agitation and neuropathic pain effectively. However, it can elevate blood ammonia levels, which might lead to clinically significant situations such as hyperammonemic encephalopathy. Valproic acid-induced hyperammonemic encephalopathy may occur in people with normal liver function, despite therapeutic doses and serum levels of VPA. Here we present a patient who has been on valproic acid for more than 7 years for treatment of Schizoaffective disorder and dementia-related aggressive behavior. Patient developed insidiously fluctuation in attention, and appeared to be sleepy and lethargic for most of the time over the course of several days. Ammonia level testing revealed high ammonia level 68 mumole/L (range is 0-47 mumole/L), despite that liver function enzymes and valproic acid level 95.8 (range is 50-100 MG/L) were within normal ranges. Interestingly, previous research showed that elevations in plasma ammonia levels, as high as 140 mumole/L, were well tolerated, and valproic acid dose reductions were not necessary if not symptomatic (Murphy and Marquardt, 1982). A review of the literature of similar reported cases and their management will be included, in addition to discussion of the course and outcome of this case.

No. 171

Should Cruelty to Animals Be Regarded as a Mental Illness?

Poster Presenter: Yara Moustafa, M.D., Ph.D.
Co-Author: Roger Peele, M.D.

SUMMARY:
Psychiatrists' efforts to explore and analyze animal cruelty behavior have been going on for over half a century. One of the earliest observations by Margaret Mead, was that the torturing or killing of "good animals" by a child may be a precursor for a more violent act in adulthood. In this paper, not having a word, we will use "Act." We will review the definition, the differential, the epidemiology, the legal status, preventive aspects and the pros and cons of conceptualizing the Act as a mental disorder. The Act refers to being cruel to animals and insects without sexual pleasure in doing so. It differs from zoosadism and zoophilia is that there is no sexual pleasure or attraction in being cruel to animals and insects. We are referring to intentional acts that

cause pain or suffering, such as beating, choking, dragging, burning, suffocating, drowning, kicking, stomping, mutilating, stabbing, throwing, etc. We are not including cruel behavior that is part of overworking farm animals, animal theft, dog or cock fighting, or hunting. While the Act might be part of conduct disorder or antisocial personality disorder, the Act only refers to the behavior of cruelty, not the other findings. We will cover DSM-5's expectations as to defining a mental illness. Moreover, investigating the motives behind the act of animal cruelty showed that inmates who abused animals out of fun in their youth was the most statistically salient motive for predicting later interpersonal violence. Taken together, Animal Cruelty Syndrome is particularly important for the Public health Sector, and should be part of public health policies.

No. 172

Paraphilia or Paraphilic Disorder? Dilemma for the Providers and Parents

Poster Presenter: Reena Kumar, M.B.B.S.
Co-Author: Jane Agnes Ripperger-Suhler, M.D.

SUMMARY:

Praaphilic disorders are not the most common cases seen in the hospital setting, Even if the pt is suffering from paraphilia, pt might not share it with the provider because of the shame associated with the disorder. Paraphilia denotes intense and persistent sexual interest other than sexual interest in genital stimulation or preparatory fondling with phenotypically normal, physically mature, consenting human partners. Paraphilia by itself does not necessarily require or justify psychiatric treatment in itself. Paraphilic disorder is defined as "a paraphilia that is currently causing distress or impairment to the individual or a paraphilia whose satisfaction has entailed personal harm, or risk of harm, to others".[5] One would ascertain a paraphilia (according to the nature of the urges, fantasies, or behaviors) but diagnose a paraphilic disorder (on the basis of distress and impairment). In this conception, having a paraphilia would be a necessary but not a sufficient condition for having a paraphilic disorder." Paraphilic disorder = paraphilia + distress/harm to self or others By this case report we hope to increase the awareness of this rare disorder and the stigma associated with it. As not all the patients with paraphilia become sexual offenders, but if parents and society's outlook towards the praphilia doesn't improve, then we will be increasing patient's mental illness, like what happened in this case and may be adding to the number of suicides.

No. 173

Paraphilia Go! A Case Report of a 14-Year-Old Male With Rare Co-Existing Vorarephilia and Toonophilia Who Was Admitted With Psychosis

Poster Presenter: Meredith A. Okwesili, M.D.
Co-Authors: Sindhura Kunaparaju, M.D., Candace Romo

SUMMARY:

Paraphilias are rare disorders characterized by bizarre or unusual preferences and acts which are repeated and preferred to normal sexual activity. In this poster, we present a rare case of co-occurring paraphilias in a 14 year old hispanic male patient with no previous psychiatric history, admitted to the inpatient unit with superficial cutting and command auditory hallucinations to end his life. He reported having a "nervous breakdown" after his mother took away two of his plush toys; "mega evolution/mega Gardevoir." As per collateral information from his mother, she walked in on the patient performing sexual acts on his Pokemon plush toys. He denied any command auditory hallucinations regarding performing sexual activities. He reported the emergence of hallucinations following psychosocial stressors such as bullying which began two years prior. He was often seen to be isolative with a decrease in memory and concentration. He was diagnosed with toonophilia, among other diagnoses, as he expressed obsessive sexual thoughts about Gardevoir with feelings of anxiety, confusion and conflict with self. Vorarephilia ("vore") is an infrequently presenting paraphilia, characterized by the erotic desire to consume or be consumed by another person or creature. In addition to his love affair with the Gardevoir, he reported watching "vore" multiple times a day in order to relieve stress/anxiety. Few data exists on vore, but there have been some cases where vorarephilic interests were expressed. Because this sexual interest cannot be enacted in real life due to physical and/or legal restraints, vorarephilic fantasies are often composed

in text or illustrations and shared with other members of this subculture via the Internet. With the emerging use of social media and internet use, there is increasing scope for an emergence of rare paraphilias such as vorarephilia and toonophilia in the adolescent population. In this poster, our goal is to educate, create awareness, and discuss the challenges and importance of recognizing such paraphilias, in regards to the well-being of children and adolescents.

No. 174

Case Report: Topiramate-Induced Hypokalemia and Its Associated Risks in Combination With Other Psychiatric Medications

Poster Presenter: Ghulam Sajjad Khan, M.B.B.S.
Co-Authors: Shivanshu Vijaykumar Shrivastava, M.B.B.S., Juvaria Anjum, Najeeb U. Hussain, M.D., Ketan A. Hirapara, M.B.B.S.

SUMMARY:
In our case 31-year -old African American male with past psychiatry history of paranoid schizophrenia was presented for acting bizarre, sexually inappropriate behavior and hearing voices. Initially guarded and internally preoccupied. He was started on Clozapine, Fluoxetine and Topiramate. His initial EKG showed QTc prolongation and labs showed electrolyte imbalance of low Potassium levels. Patient was started on K- DUR. Fluoxetine was discontinued and repeat EKG was normal towards the end of first week. His potassium levels were still low. Potassium treatment was titrated and given. During his second week of inpatient hospital course patient's EKG was normal, less bothered by the auditory hallucination and more cooperative. Therefore, the concomitant use of Fluoxetine along with Topiramate and other psychiatric medications lead to the QTc prolongation. Our Poster will discuss about Pro arrhythmia caused by QTc- prolongation and multiple factors need to be considered for precipitating such an event including metabolic imbalance like hypokalemia, combination of two or more drugs affecting through different mechanisms and leading to cause the same result, as Topiramate act through many mechanisms including inhibiting carbonic anhydrase (lead to metabolic acidosis/ Hypokalemia). Novel antidepressants, fluoxetine (SSRI's), prolong the QT interval by inhibiting potassium channel. Patient's response to a drug is very individual and therefore an individualized system of drug administration and monitoring needs to be developed.

No. 175

Protracted Amnesia/Catatonia Post Anesthesia: Case Report, Status Post Propofol Induced Routine Anesthesia, Protracted Amnesia, and Catatonia Symptoms

Poster Presenter: Ghulam Sajjad Khan, M.B.B.S.
Co-Authors: Erin Zerbo, M.D., Juvaria Anjum

SUMMARY:
A 32-year-old female with no past psychiatric history, presented to the emergency department with four-day history of amnesia, confusion and paucity of speech following gastroscopy and colonoscopy performed under monitored sedation using Propofol. Following the procedure, the patient exhibited minimal speech, redirected multiple times and had difficulty with recall for several hours. Diazepam was given with little improvement and patient was discharged home with family and a prescription and were told to return to the hospital if symptoms did not improve. She subsequently returned to the hospital and received full neurological workup which was negative. Later, patient presented to the psychiatric emergency room, she was guarded, disinterested, mute with blunted affect, cognition was grossly intact, but was unable to be assessed for thought process and content. She was given Lorazepam and was admitted to the inpatient psychiatric unit where she was evaluated for mutism, amnesia, blank stare, poor eye contact and psychomotor deficits. Patient denied any symptoms of depression, mania, psychosis, suicidal or homicidal ideation. She was restarted on lorazepam, titrated dose based upon her response. There was a significant improvement noticed in her memory, mood, and ability to perform routine task. In our poster, we will discuss our case report of response to lorazepam and co-occurring catatonia with amnesia and the importance of diligence to diagnose especially in postoperative states.

No. 176

Exposure to Dim Light at Night During Sleep May

Have Effect on Next Day Fatigue in Humans
Poster Presenter: Ahreum Cho
Co-Author: Chul-Hyun Cho

SUMMARY:
Background: Exposure to light at night has become pervasive in modern society. Effect of dim light at night (dLAN) exposure during sleep on human's fatigue is not well recognized. We aimed to study the impact of dALAN exposure during sleep on human's fatigue through well-designed experimental study. Methods: 30 healthy young male volunteers from 21 to 29 years old were enrolled into the study. They were randomly divided into two groups depending on light intensity (Group A: 5 lux and Group B: 10 lux). After exclusion of problematic sleepers, 20 male subjects finished the whole study. Data about the fatigue were gathered from each participant after each night with no light (Night 1) followed by the next night (Night 2) with two different dim light conditions (5 or 10 lux) by means of self-reported fatigue scale. Results: Exposure to dLAN during sleep was significantly associated with increased overall fatigue ($F=19.556$, $p<0.001$) and ocular discomfort ($F=5.671$, $p=0.028$). But, there was no significant group-night interaction. Conclusion: We found that dLAN during sleep probably affects human's fatigue in some aspects. These findings suggest that dALAN during sleep exerts a negative effect on human's fatigue.

No. 177
Pediatric Bipolar: New-Onset Bipolar Disorder
Poster Presenter: Hadia Crider

SUMMARY:
BACKGROUND:16 year old male with no past psychiatric history seen for the first time in Psychiatry clinic for bizarre behavior starting 1.5 months ago. On assessment patient was disorganized and circumstantial. He endorsed AH/VH hallucinations with a male voice talking to him outside his head. His friends observed him talking to himself when nobody was present multiple times. Patient was responding to internal stimuli during assessment and would get distressed when discussing the voices. Patient screened for mania with history from mom. Mom reported over the past month patient stayed up for two straight days, would speak rapidly, and was rearranging his room late at night. He was not acting like himself. He endorsed delusional thoughts regarding the military. Patient endorsed suicidal thoughts with a plan to shoot himself. Patient was referred for acute inpatient psychiatric stabilization from clinic. He was diagnosed with Bipolar Disorder Type 1 with psychotic features. This was confirmed with psychological testing with the Minnesota Multiphasic Personality Inventory Adolescent (MMPI-A). He is currently taking Lithium 300mg BID, Seroquel 100mg qhs, and Trazadone 50mg qhs for mood stabilization, psychotic features, and insomnia and is stable. Patient's biological father had similar psychiatric issues. DISCUSSION It is challenging to diagnose a child with Bipolar Disorder. Children find it difficult to verbalize their feelings. Their symptoms can have different meanings based on their developmental levels. There is a high rate of comorbid psychiatric disorders with pediatric bipolar disorder (ADHD, Anxiety, substance use, ODD, Conduct Disorder, Autism, and OCD). Symptoms overlap with these comorbid conditions, making it hard to accurately diagnose Pediatric BPD. Statistics show for each year of untreated illness, bipolar youth have a 10% lower recovery rate. This indicates the importance of an accurate diagnosis and proper treatment of BPD early on in the disease process. CONCLUSION Pediatric Bipolar can be difficult to diagnose due to comorbidities as well as symptom presentation. Children are still developing their brains, especially the frontal cortex. The frontal cortex performs reasoning, planning, impulse control and judgement. Since teenagers are often still developing this area of their brains they have a higher tendency to be impulsive and make poor decisions, which are also diagnostically indicative of bipolar disorder. This makes it difficult to differentiate between normal teenage behavior and manic symptoms. The early recognition and maintenance treatment of BPD in children is of extreme importance to reduce psychosocial issues that can occur including social isolation, poor academic performance, and legal issues. Treatment includes family and school psychoeducation, family and individual therapy, and mood stabilizers (Lithium, antiepileptics, and antipsychotics).

No. 178

The Role of Laboratory Values in Medication-Induced Female Sexual Dysfunction in the Outpatient Setting

Poster Presenter: Aisha R. Mondal, M.D.

SUMMARY:

Patients with major depressive disorder or bipolar disorder have a high prevalence of sexual dysfunction, including lowered sexual desire, compared to the general population. Additionally, medications used to treat these conditions may further contribute to sexual dysfunction. Hormonal contraceptives and SSRIs are two classes of medications that may decrease sexual desire in women. The two patient cases presented reflect the potential utility in ordering specific hormonal lab values to aid in diagnosis and treatment of medication-induced sexual dysfunction. Each case features a female patient in her early 20's in a committed, long-term relationship, who after being treated with both an oral hormonal contraceptive and a SSRI, experienced a significant decrease in sexual desire. In both cases, the contraceptive and SSRI were started in close proximity to each other, making it difficult to distinguish from history alone the agent most likely contributing to the sexual dysfunction. The first patient had attempted tapering off SSRI through her PCP and switching to a transvaginal hormonal contraceptive through her OBGYN with worsening mood symptoms and no improvement in sexual desire before presenting to outpatient psychiatry for evaluation, prompting hormonal blood tests. Interpretation of results and response to recommendations will be discussed and compared to the management of the second patient. This presentation will demonstrate how to use laboratory values (TSH, testosterone, SHBG, prolactin, DHEA-S) can be incorporated into assessment and management of decreased sexual drive.

No. 179

Oncosexology and Psychiatry: A Portuguese Approach

Poster Presenter: Ana Luisa Almada
Lead Author: Filipa Henriques
Co-Author: Lúcia Monteiro

SUMMARY:

Background: Cancer diagnosis and its treatment can deeply compromise patient´s physical, psychological and social balance and functioning. One of the most affected areas are intimacy and sexual life. Studies show that about 59% to 79% of people with cancer have a significant decrease in sexual activity. Besides its huge prevalence, sexual problems or malfunctions are seldom screened or prevented. OncoSexology rose as a clinical and multidisciplinary discipline focused on understanding, screening, preventing and treating, as much as possible, the sexual side effects of cancer disease and its treatments, in order to improve sexuality and general quality of life of the patients and their partners. This work focuses on the role of psychiatry in Oncosexology Clinic, at Portuguese Institute of Oncology of Lisbon (IPO - Lisbon). Methods: It is a descriptive, observational and retrospective analysis of patients followed at the OncoSexology/Psychiatry Outpatient Clinic, in IPO - Lisbon, during 2016. The characterization focused in demographic (age, sex, race, marital and parental status), oncological (referrals, diagnosis and treatment), sexual (diagnosis and treatment) and other psychiatric factors (co-morbidities). Results: In 2016, 79 Oncosexology/Psychiatry appointments were carried out. A total of 45 patients were observed, 57,8% female (n = 26) and 42,2% male (n = 19), with an average age of 50 years. The majority of the patients were married (73.3%) and had children (68.9%). Majority of referrals came from Breast Clinic (n = 16, 35.6%). The most prevalent oncologic diagnoses were Breast cancer (n = 19, 42.2%) and Prostate cancer (n = 7, 15.6%). Most cancer treatments carried out were surgery (82.2%), radiotherapy (68.9%) and chemotherapy (62.2%). The mean gap time from cancer diagnosis to the first oncosexology appointment was approximately 2.5 years. The most prevalent sexual diagnoses were Genito-pelvic pain/penetration disorder (n = 18), Erectile disorder (n = 12) and Female sexual interest/arousal disorder (n = 12). Almost half of the patients had another concurrent psychiatric diagnosis (n = 21, 46.7%), mainly depressive disorder (57.1%). All patients received brief psychosexual interventions, including psychoeducation, support information, and symptom management. Other sexual specific interventions included vaginal rehabilitation with lubricants, moistures and digital massage (62%) and

selective phosphodiesterase-5 inhibitors (24.4%). Some patients also needed antidepressants (35.6%) and brief psychotherapy to improve coping strategies or marital life. Discussion/Conclusion: Our study is a descriptive characterization of the patients observed at Psychiatry in Oncosexology outpatient Clinic, in IPO – Lisbon, over 2016. Psychiatric disorders are common in Oncosexology Clinic. Psychiatric expertise is complementary, but essential in a multidisciplinary OncoSexology Clinic.

No. 180

Less Is More: Importance of Antidepressant Drug Interactions

Poster Presenter: Pratik Bahekar, M.B.B.S.

SUMMARY:

Buspirone is a partial 5HT1A agonist at the presynaptic hetero receptors and post-synaptic receptors modulating the increased release of serotonin. Buspirone is used to improve libido in those who have decreased libido due to use of psychotropic. We submit a case report; hyper sexuality with buspirone administration after several different trials. With Naranjo adverse drug scale score of 10 buspirone was “definitely: responsible for the side effect. Mr. X is 80-year-old male retired Airforce veteran with a previous history of Major Depressive Disorder, General Anxiety Disorder, and insomnia. The patient was diagnosed with stage IV Non-Hodgkin’s Lymphoma, drug induced cardiomyopathy and atrial fibrillation and was on polypharmacy for medical and psychiatric illness. He had limited symptoms relief with selective serotonin reuptake inhibitors, selective norepinephrine reuptake inhibitors, and mirtazapine. The patient was initiated on 5mg of buspirone and was titrated to 15mg, with a good clinical resolution of symptoms. However, with increasing doses of buspirone, Mr. X reported hypersexual thoughts and increased sexual drive. After three months of continued treatment, the patient began experiencing distressing obsessional hypersexual ideation. Of note, he reported no erections in the past three years and did not have intercourse in 40 years. Due to reported feeling guilty about his hypersexual thoughts, buspirone was slowly tapered off. Which resulted in a gradual decrease of hypersexual thoughts. After six months, Mr. X requested another trial of on buspirone as the medication helped relieve anxiety symptoms. Mr. X was restarted on buspirone 10mg daily which resulted in resurfacing of hypersexual thoughts. Buspirone is primarily metabolized by CYP2D6, CYP3A4, CYP3A5 and CYP3A7 cytochrome enzymes. Mr. A was on carvedilol, digoxin, flunisolide, glipizide, simvastatin, tamsulosin, torsemide, tramadol, Trazodone, Mirtazapine, & warfarin for his psychiatric problems and medical comorbidities. The medications which were metabolized by the same cytochrome enzymes had substrate-substrate interaction, inhibitor-substrate interaction and inhibitor-inducer-substrate interactions. Increase in the buspirone levels and may have contributed to the hyper sexuality. Authors acknowledge genetic variations are seen in the cytochrome enzymes functioning and no genetic studies were done in the patient. With no prior published case reports, we report for the first time that low to moderate use of buspirone causes hyper sexuality which is reversed of the drug depicting the causal relationship between the medication and symptoms. Thus, an association of hyper sexuality with buspirone is conceivable.

CANTAB (Cambridge Neuropsychological Test Automated Battery) Reveals Impaired Sustained Attention in Offspring of Bipolar Parents and Healthy Controls

Poster Presenter: Ayesha Masood

SUMMARY:

Background: Bipolar disorder (BD) is mainly characterized by dramatic mood shifts due to the biased process of emotional information. An overlooked aspect of BD is the potential development of cognitive deficit amongst various cognitive domains that have influence on course of illness. We used Cambridge Neuropsychological Test Automated Battery (CANTAB) to analyze if group of Bipolar Offspring (BPO) shows any trait of deficit compared to healthy controls (HC). Methods: 26 participants (age 7-17 years inclusive; 10 bipolar offspring and 16 healthy controls) were enrolled

from an outpatient specialty mood disorders clinic. CANTAB cognition test battery was administered with desired modules. The rapid visual processing (RVP) task is a measure attention and psychomotor speed. We used post-hoc ANOVA to compare results of different cognitive tests between groups while adjusting for age and sex. Results: The RVP mean latency ($p = 0.321$) is significant between HC and BPO. Compared to HC, bipolar offspring have a longer response time therefore showing lower sustained attention span. Conclusion: Preliminary data reveals early evidence of cognitive function deficit in bipolar offspring group by means of lower sustained attention tendency when compared to HC. Impaired sustained attention can serve as a biological marker for prodromal diagnosis and improved prognosis. Further work is necessary to see the neural underpinnings of this tendency in bipolar offspring in order to improve prognosis of such individuals.

No. 183

Hormone Treatment in Transgender Patients and Mental Health

Poster Presenter: Gaurav Kumar, M.D.

SUMMARY:

Gender dysphoria is defined as the discomfort arising in some individuals from the incongruence between their gender identities and their external sexual anatomy at birth. Hormone replacement therapy for transgender individuals involves sex hormones or other hormonal medications which are administered to transgender individuals to synchronize their secondary sexual characteristics with their gender identity. However, adverse effects of long term hormone treatment and psychiatric outcomes in the transgender population have not been well studied. This case study focuses on a patient undergoing hormone replacement therapy and subsequently developing a manic episode, requiring hospitalization. Studies have shown that androgenic steroid use is associated with increased aggressiveness, heightened irritability, hyperactivity, changes in libido, and unprovoked violence. The risk of suicides seems to be increased in male-to-female patients, but appears to be similar to the general population in female-to-male patients undergoing hormone replacement therapy. Hormone therapy also appears to have a beneficial effect on depression. Management of patient's hormone treatment medications, as well as consideration of psychiatric medications to treat the patient's mental illness, while evaluating the overall risks and benefits of utilizing hormone replacement therapy for these individuals are discussed.

No. 184

Don't Call Me "He" OR "She": A Case Report on Prepubertal Gender Dysphoria

Poster Presenter: Lovejit Kaur, M.D.
Co-Author: Sourav Sengupta

SUMMARY:

Gender dysphoria in children is defined in the DSM-5 as a longstanding "marked incongruence between one's experienced/expressed gender and assigned gender." We intend to describe a case of prepubertal gender dysphoria and discuss clinical issues related to treatment. A 9-year-old Chinese female,adopted by Caucasian parents at the age of 10 months from China, presented for psychiatric evaluation. The patient has received mental health treatment since the age of 5 and has been diagnosed with attention-deficit/hyperactivity disorder, autism spectrum disorder, reactive attachment disorder, and generalized anxiety disorder. She has been tried on multiple stimulants and selective serotonin reuptake inhibitors in the past, however has not achieved remission of symptoms, due to being an ultra rapid metabolizer of CYP2D6. She is currently prescribed escitalopram and long-acting methylphenidate, and has had marked remission of her symptoms. The patient is currently enrolled in a social skill building group due to her history of autism spectrum disorder and limited ability to understand social cues. The patient first started to have discomfort with gender at the age of 6 years old and preferred to be called "He" instead of "She.". There were also time periods when the patient did not like to be identified as either gender. The patient began dressing as a male, including getting a short hair cut and choosing games traditionally played by boys. The patient preferred to play and identify with male peers. The patient preferred to be addressed by first name and the use of gendered pronouns would often lead to yelling and aggression. The patient would get into fights

with other children in school or summer camp due to the discomfort and anxiety experienced in anticipation of being judged because of a female appearance. Treatment of gender dysphoria in children can be challenging due to limited community resources and the stigma related to it. Collaboration with the school and therapist and parent psychoeducation play integral roles. The patient is working on the goals of exploring gender identity role and expression, alleviating internalized transphobia and promoting resilience. Psychotherapy is individualized varying on the emphasis on individual's needs and discomfort. Hormone therapy and surgery in prepubertal age is not well researched as there have been studies which describe some children and adolescents grow out of gender dysphoria due to social, environmental or sexual experiences and might experience remission of dysphoria. Exploring into gender constancy and gender identity role are most crucial tasks at this developmental stage.

No. 185

Coincidence or Correlation? A Genetic Anomaly and Gender Dysphoria in an Adolescent in Psychiatric Residential Treatment

Poster Presenter: M. M. Naveen, M.D.

SUMMARY:

Background/Objectives: GG is a transgender adolescent with gender dysphoria. This new term in DSM-5 is characterized by marked distress over the incongruence between one's birth and identified gender. GG also has a rare deletion on chromosome 6, specifically 6q14.1-14.2. To date, no studies note an association between chromosome 6q deletions and gender development. This report encourages readers to consider whether chromosome 6q deletions impact gender development and contribute to gender dysphoria. Methods: The authors of this abstract worked with GG in a residential treatment center over a period of 6 months. She was evaluated on a regular basis and received medication management. In addition to a thorough chart review, the authors spoke with GG's father and several treatment center staff, including nurses, social workers, clinical milieu managers, and mental health workers. Results: In addition to gender dysphoria, GG suffers from major depression and demonstrates several characteristic features of borderline personality disorder, most notably recurrent self-injury. This is consistent with results from a recently published study on the mental health disparity between transgender and cisgender adolescents, which notes a 2- to 3-fold increased risk for adverse mental health outcomes in transgender youth. A number of factors contribute to this, in particular peer bullying, social rejection, and a lack of family support. All of these are challenges faced by GG. Discussion: Clinicians should keep in mind that chromosome 6 deletions may influence gender development. Accordingly, an adolescent with gender dysphoria who has notably distinctive facial features, engages in recurrent self-injury, or manifests other symptoms of borderline personality disorder may warrant karyotype analysis to evaluate for such a deletion. To best establish and maintain a therapeutic relationship with gender nonconforming youth, it is important to eliminate bias and judgment and simply listen to and learn about what a youth is experiencing and feeling about his or her gender.

No. 186

Beyond the Gender Binary: A Trans Perspective From India

Poster Presenter: Nandini Murali

SUMMARY:

The Indic tradition is supportive of pluralities in gender and its diverse expressions across the gender spectrum. Represented in murals and stone carvings, the iconic form of Ardhanareeshwara (half woman and half-man) is one of the many instances of the validation of non-binary gender representations. In India, the community of trans women or male to female (m2f) trans persons, is popularly known as hijra, aravani or thirunangai. Although a highly visible gender minority, they are one of the most marginalized, ostracized and stigmatized gender minority people in the country. In current gender and diversity discourse, there has been a perceptible shift from the traditional binary notions of sex/gender to a spectrum model that recognizes the diversity, pluralities and fluidity of non binary sex and gender. The incongruence between the anatomical sex and gender identity is termed Gender Incongruence, or Trans Genderism and the resulting feelings of confusion, loneliness, anxiety, guilt and

shame are termed Gender Dysphoria. In India, trans gender is an umbrella term that includes a range of people with diverse gender identities and experiences and includes pre-operated effeminate or feminized men (kothis), postoperative trans gender women, and non-operated trans sexual people (both of whom identify with the gender that is diametrically the opposite of their biological sex), and cross dressers. A male to female (m2f) trans gender person is referred to as a trans woman, and a female to male (f2m) trans gender person as a trans man. The concept of gender binary or gender binarism is crucial to understand the social exclusion and vulnerabilities experienced by Trans Gendered individuals. The term describes a societal worldview that splits people into opposing male and female, sex and gender, masculine and feminine—all of which are seen as hierarchical, opposing and disconnected and compartmentalizes people into male and female gender roles, identities and attributes. People who are gender diverse are marginalized and thereby excluded because they do not conform to normative gender expectations and associated with one's biological sex.
Heteropatriarchy refers to the dominance of heterosexual males in society and is organized in such a way that the power endowed on men by patriarchy gets carried into heterosexual relationships. Transphobia refers to the widespread hatred and avoidance of Trans Gender people whose gender identity and experience are at variance with their biological sex. Ostracized their vulnerabilities are compounded by social institutions such as the family, school, law and work place. The presenter highlights the story of a resilient woman living life on her own terms, as a trans woman with dignity and courage as she weaves the aesthetic, political and ethical warp of the trans community into a narrative of hope and triumph.

No. 187

Psychiatric Challenges for the Transsexuals After Sex Reassignment Surgery

Poster Presenter: Syed Saleh Uddin, M.D.
Co-Author: Javeria Sahib Din

SUMMARY:

Psychiatric challenges for the transsexuals after sex reassignment surgery Syed Saleh Uddin M.D, Javeria Sahib Din M.D, Asghar Hossain M.D Abstract Background "Gender identity disorder of childhood" (GID) was recognized as a "disorder" in 1981. The word "transgender" is an umbrella term used for persons who do not identify into their assigned gender and hence challenge the customs of their gender. Transsexuals are individuals who desire to be surgically transformed, by a surgery known as sex reassignment surgery. Sex reassignment surgery (SRS) is performed in transsexuals to make their physical appearance according to their desired sex. Sometimes, those individuals who undergo SRS are referred to as trans sexed individuals. Method A prospective review will be used to study challenges faced by transgender psychiatric patients after sex reassignment surgery. Patients will be interviewed; electronic and paper charts will be reviewed. Available literature from PubMed is reviewed Objective Our goal is to highlight the factors involved in stabilization of transsexuals during and after sex reassignment study. Conclusion Variable results are available regarding the psychiatric morbidity associated with sex reassignment surgery i.e., the psychiatric challenges faced by the transsexuals after sex reassignment surgery. Improvement in psychological problems has been reported in many studies. But there is some psychiatric manifestation after sex reassignment surgery. Some of the conditions reported include regret, suicide attempts etc., after SRS. A meta-analysis study on the psychological outcomes after SRS reports that 80 percent of transsexuals improve in terms of quality of life and gender dysphoria. A Swedish study reports an increase in mortality, psychiatric inpatient hospitalizations and suicide rate after SRS. Higher criminal convictions have also been reported in female to male transsexuals. Increase in cardiovascular mortality and malignancies has also been observed after transformation. Sex reassigned individuals have reported friends and family as the greatest support factor after SRS. Surgeons and psychologists were also among persons from whom transsexuals were seeking psychological support. Sex reassigned individuals require a prolonged psychiatric care after SRS to prevent psychological decline. Literature review Gender identity is the term used to recognize a person as male or a female. It does not include only the appearance of genitalia, but it also comprises the innate desire and role as a

man or a woman, and as a girl or a boy. Similarly, the inability to psychologically accept the designated gender and its associated discomfort is termed as Gender dysphoria. The term sexual orientation does not depend on gender identity. Gender variance or gender nonconformity is characterized by having interests that are not in accordance with the cultural norms of the assigned gender. "Gender identity disorder of childhood" (GID) was recognized

No. 188

Gender Dysphoria (Gender Identity Disorder) as a Precipitator of Psychosis and Poor Prognosis in Schizophrenia: A Case Report

Poster Presenter: Muhammad Navaid Iqbal, M.D.
Co-Authors: Mehwish Hina, Ghulam Sajjad Khan, M.B.B.S., Ali Raza, Asghar Hossain, M.D.

SUMMARY:

Background: Schizophrenia and gender dysphoria are the two psychiatric disorders, which may mutually overlap or coexist with each other. Gender Dysphoria can be defined as distress experienced by the patient due to mismatch between biologic sex and gender identity. Early diagnosis and prompt treatment of gender dysphoria may prevent psychotic decompensation and prevent deterioration of functional status in patients. It is very imperative to manage the psychosocial stressors associated with gender dysphoria, which may culminate into various psychiatric disorders including schizophrenia. Untreated cases of gender identity disorder in context of schizophrenia have substantial impact on long term prognostic outcome. **Objective:** The primary objective of this case report is to emphasize the need to effectively manage gender dysphoria before it may give rise to any significant psychiatric illness like schizophrenia. This also highlights how coexistent schizophrenia and gender dysphoria impact long-term prognostic outcome. **Case:** We present a case of 20-year-old male to female transgender patient with past psychiatric history of schizophrenia who was admitted to our inpatient psychiatric unit secondary to worsening of her psychosis and suicide attempt. She had multiple inpatient hospitalizations due to her mental illness and also noncompliance to her medications. Patient started transitioning from male to female at age 16 years and started hormonal therapy. She started having psychotic and mood symptoms during her transitioning phase. Although patients gender change was well accepted by her family and friends, it became a significant precipitating factor in worsening of her mental illness and contributed to her poor functioning and quality of life. **Discussion:** In the present day world, gender dysphoria has increasingly shown predisposition to precipitation of psychosis. This has been supported by available literature and emphasize on numerous psychosocial stressors induced by social society, which ultimately affect patients experiencing gender dysphoria. Few case reports on coexistence of schizophrenia and gender dysphoria highlights the poor prognostic outcome because of its complexity and inadequate treatment. As seen in our reported case, patient's gender dysphoria was leading cause for psychotic decompensation and subsequently impinging on long-term prognosis. Researchers advocate strongly for effective management of gender dysphoria to prevent over burden of psychotic diseases for a healthier society; hence, emphasizing the significance of our case report. **Conclusion:** In light of this case report we recommend managing cases of gender dysphoria promptly and effectively before they culminate into a psychotic disorder. Inadequately treated cases may have adverse outcome and subsequently impacts future prognosis. We recommend further research in this regard to prevent overwhelming burden of psychotic illnesses in our society.

No. 189

Precipitation of Post-Physical Restrain Delirium

Poster Presenter: Muhammad Navaid Iqbal, M.D.
Co-Authors: Mehwish Hina, Naveed Butt, Asghar Hossain, M.D.

SUMMARY:

Physical restrain is one the treatment modality primarily used to manage agitated or aggressive behavior in psychiatric inpatient units and nursing homes. It's rationalized use prevents physical injuries to patients which they may sustain due to their behavioral outbursts if not promptly contained. There is wide array of etiologies of patient's aggressive behavior ranging from overt psychosis to deliberate self-injury due to suicidality. Restraining

on one hand is effective to prevent self-injury, but on contrary, may precipitate some complications due to variety of reasons. Delirium stands out as one of the common psychiatric manifestation patients may experience during post restrain phase. It can be defined as fluctuating sensorium with waxing and waning pattern, primarily affecting middle age and geriatric population in heath care setting; which could be either hyperactive, hypoactive or mixed type. Transient hypoxia to neurons seems to be the etiological factor in such cases, which partly attributes to co-existent acute medical comorbidities like congestive cardiac failure and chronic obstructive pulmonary disease. Physicians recommend monitoring for early signs of decompensation like hyperventilation, panic attacks, and persistent agitation while in physical restrains; as they tend to precipitate hypoxia culminating into acute delirium. Generally, physical restrains are used as last resort to contain behavior when intervention with chemical restrains remains unsuccessful or physical restrains imminent to prevent patient's physical injury. Close monitoring of post restrain status of patients is very imperative. It's highly advisable to adequately medicate such patients as persistence of aggressive and agitated behavior while in physical restrains may lead to infliction of overt physical injuries and prolong immobilization of extremities of patients post restrain. Considering the high rush of catecholamines in such patients due to their aggressive behavior, cautious use of short acting benzodiazepines along with antipsychotics in psychotic patients help to effectively manage patient's aggressive behavioral outbursts. While onset of delirium depends on multitude of factors; its early management and detection of subtle warning signs helps in effectively managing acute physically aggressive episodes without precipitating complications like delirium. Skilled interpersonal communication and frequent patient interaction of the physician also helps in reducing the time of physical restrain, which leads to less probability of any complications. In extreme cases, if delirium not managed promptly and effectively may led to death due to cardiovascular decompensation, which potentially can be avoided with collaborative team effort. This literature review emphasis upon the need to intervene in timely manner in cases of physical restrains to prevent complications of delirium in context of hypoxia or asphyxia.

Case: Recent-Onset Psychosis in a 56-Year-Old Male

Poster Presenter: Jayson Takeji Masaki, M.D.

SUMMARY:

A 56-year-old single white male presented to inpatient psychiatry unit from a nursing home with progressive and rapid psychotic decompensation over the course of 1 year , with prominent worsening in the last 3 months as noted by 3 hospital readmissions for what appeared to be treatment resistant schizophrenia. Admission labs were significant for moderate pancytopenia, prompting a repeat CBC confirming pancytopenia. Follow-up testing for HIV screening and a CT head was done which showed positive HIV serology and imaging with impression of extensive white matter changes and generalized mild cerebral atrophy. HIV positive status was confirmed and testing for opportunistic infections was done to rule out any complicating medical factors. The patient was started on anti-retroviral therapy (in addition to antipsychotic olanzapine) and made a significant recovery as evidenced by no further psychiatric hospitalizations in the following 6 months. This is a case of Progressive Multifocal Leukoencephalopathy (PML), a rare and serious opportunistic brain disease caused by reactivation of latent John Cunningham virus (JCV) in immunocompromized individuals, most commonly seen in HIV/AIDS patients. Left untreated, rapid neurological deterioration and fatal progression ensues with most patients dying in a few months. Symptoms are variable, but often presentation is mistaken for psychiatric disorders due to cognitive impairment and psychosis. Since there is no specific treatment for JCV infection at this time, the clinical approach is addressing the underlying cause of immunosupression. In this case, initiating highly active antiretroviral therapy to treat HIV is the best therapeutic option, which may halt further progression of neurological damage and may reverse some psychiatric symptoms if such symptom pathology is due to inflammatory processes in the brain. Paradoxical transient worsening of symptoms during initial treatment may occur, which clinicians

should be aware of as it may cause undue alarm and questioning of therapeutic efficacy if not expected.

Expanded Clinic-Based Mental Health Services: Association With HIV Viral Suppression

Poster Presenter: Raina Aggarwal, M.D.
Co-Authors: Kathleen McManus, Rebecca Dillingham

SUMMARY:

Background: The University of Virginia Ryan White HIV Clinic increased clinic-based mental health (MH) services including substance use counseling in 2013. The study objectives are to characterize the changing demographics of the people living with HIV (PLWH) who initiated MH care and to determine MH services' effects on HIV outcomes, specifically HIV viral suppression. Methods: The cohort included PLWH who received clinic-based MH services 2012-2014. Cohorts A and B initiated MH care before or during 2012 and during 2013-2014, respectively. Demographics were analyzed, and for Cohort B, viral suppression rates for pre- and post-MH care initiation were compared. Results: Cohort A (n=130) represents 19% of all 2012 clinic clients; Cohort B includes 182 subjects. By 2014, 41% of all clinic clients had established MH care. MH visits increased from 385 in 2012 to 941 in 2013 and 1,183 in 2014. Compared with Cohort A, Cohort B had almost three times the number of subjects with CD4 counts below 200 (p=0.02). 96% of Cohort A had been prescribed antiretroviral therapy (ART) before MH care initiation compared with 82% of Cohort B (p=0.009). About one-third of Cohort B had detectable viral loads compared to less than 20% of Cohort A (p=0.01). Cohort B received more substance use diagnoses in the year following MH care initiation compared to Cohort A (p=0.005). For those in Cohort B who had HIV viral loads in the year before and year after MH care initiation (n=170), 43% had detectable viral loads before establishing MH care. The viral suppression rates for Cohort B in the year before and after establishing MH were 57% and 87%, respectively (p<0.001). Conclusions: PLWH who gained access to MH services in 2013-2014 had lower CD4 counts. They were more likely to not be prescribed ART and to have a detectable viral load. Importantly, initiation of MH services was associated with increased rates of viral suppression. Increased access to co-located MH and substance use services helped high risk PLWH achieve optimal HIV outcomes.

Level of Experience and Attitudes Toward the Use of Physical Restraints of Acute Psychiatric Inpatients

Poster Presenter: Michael A. Landolfi

SUMMARY:
